Association of three SNPs in the PARP-1 gene with Hashimoto’s thyroiditis

Arzuhan Koc1, Muge Aydin Sayitoglu2, Funda Karakurt1, Bahadir Batar1, Mutlu Niyazoglu3, Ilhan Onaran1, Ertugrul Tasan3 and Gonul Kanigur Sultuybek1

Poly(ADP-ribose) polymerase-1 (PARP-1) has a vital role in the progression of the inflammatory response, and its inhibition confers protection in various models of inflammatory disorders. Therefore, we investigated the effect of promoter and exon variations of the PARP-1 gene on the risk for the inflammatory disease Hashimoto’s thyroiditis (HT). This case–control association study was comprised of 141 HT patients and 150 controls from a group of women in a Turkish population. Two polymorphisms in the promoter region of the PARP-1 gene, rs2793378 and rs7527192, were analyzed using the PCR-RFLP method. In addition, single nucleotide polymorphism (SNP) rs1136410, which is located at codon 762, was analyzed using bidirectional sequencing. The combined genotype and haplotype analyses of these polymorphisms were performed using SPSS 18 and Haploview 4.2. The results were statistically analyzed by calculating the odds ratios and 95% confidence interval using Pearson’s χ²-test and Fisher’s exact test (two-sided). Although we had a number of significant results, the associations became nonsignificant following a Bonferroni correction for multiple comparisons. Nonetheless, a protective factor against HT was still observed for the heterozygous genotype (TC) of SNP rs1136410 (P = 0.001), even following Bonferroni correction, and according to the rs2793378–rs7527192 combined analysis, the occurrence of the TT/GA combined genotype was significantly higher in the controls (P = 0.007). These results prove that the heterozygosity of SNP rs1136410 provides a protective effect against HT disease in a group of women in a Turkish population.

INTRODUCTION

Hashimoto’s thyroiditis (HT), which is characterized by the production of autoantibodies against the thyroid gland, is a localized autoimmune disease. HT has been found to have a 55% concordance rate in monzygotic twins.1 Repplinger et al.2 reported that there is a high prevalence for the increased occurrence of HT in women, which is seven times greater than in men. Different genetic and environmental factors are involved in the pathogenesis of this disease.3 It is well established that the chronic inflammation that occurs during the course of HT causes a significant increase in the levels of cytokines and other inflammatory mediators, which ultimately leads to the destruction of the thyroid gland.4 More precisely, the interactions of multiple genes and environmental factors can increase susceptibility to HT and the severity of the disease.5 Poly(ADP-ribose) polymerase-1 (PARP-1) is thought to be one of the candidate genes responsible for the pathogenesis of inflammatory situations. PARP-1 is thought to have an important role in the initiation of the DNA repair pathway, although high levels of its activation are also associated with increased apoptosis. Recently, it was shown that the development and progression of inflammatory diseases were impeded in PARP-1 knockout animal models that used PARP-1 inhibitors.6,7 Results from several studies have shown that the inactivation of PARP-1 protects against endotoxic shock, colitis, lung inflammation and other diseases, such as traumatic brain injury, cerebral and myocardial ischemia, stroke, rheumatoid arthritis and diabetes mellitus-associated heart cascade.8–12 Although, the exact role of PARP-1 in the inflammatory cascade is not yet known, all of the available studies on PARP-1 suggest that this gene is a strong candidate and genetic factor for the development of HT.

The PARP-1 gene (OMIM 173870), which localizes to chromosome one (1q41–43), has been shown to accommodate allelic polymorphisms that have been linked to susceptibility for various diseases, some of which are inflammatory disorders.16,17 In addition, multiple binding sites for transcription factors have been identified in the PARP-1 gene promoter region; therefore, genetic variants within this region may affect PARP-1 expression.17 Several variations (C410T (rs2793378), Poly(A)n, C1362T and G1672A (rs7527192)) have been identified in the promoter region, and there are several studies that have investigated the relationship between these promoter polymorphisms and the pathogenesis of many diseases.16,17 In addition, the active-site polymorphism T2444C (rs1136410) (also known as Val762Ala), which causes a T to C, Val to Ala change in exon 17, was identified by Cottet et al.18 According to Wang and colleagues, the T2444C polymorphism reduces the enzymatic activity of PARP-1 by ~40%.16,19,20

In this study, we questioned whether two promoter polymorphisms (rs2793378 and rs7527192) and an active-site polymorphism (rs1136410) in the PARP-1 gene could predispose individuals to HT disease in a female Turkish population.

PATIENTS AND METHODS

Study subjects

One hundred and forty-one women who were diagnosed with HT in the Endocrine and Metabolic Diseases outpatient clinic at Cerrahpasa Medical
Genotyping of the PARP-1 polymorphisms

The genomic DNA from the study subjects was isolated using an ethanol precipitation method. The concentration and purity of the DNA was measured on a NanoDrop Spectrophotometers (NanoDrop Technologies Inc., Wilmington, DE, USA) and determined using a 260/280 nm optical density ratio. The PARP-1 C410T and G1672A genotypes were determined using a polymerase chain reaction (PCR) based restriction fragment length polymorphism (RFLP) method. The primers used to amplify the polymorphic sites were F: 5′-TCAAGTGCCACTATC-3′ and R: 5′-GTTGAG AGCATTGCC-3′ for rs2793378, and F: 5′-GCAATGCCCTGCTCC TCAA-3′ and R: 5′-TCCCCCTTATTATTTTGAAGTCTC-3′ for rs7527192.16

The amplification products yielded a 298-base pair (bp) fragment for rs2793378 and a 187 bp fragment for rs7527192. Ten microliters of the amplification product of rs2793378 were digested with one unit of Hpy31 (New England Biolabs, Beverly, MA, USA), incubated for 12 h at 37 °C, and subjected to electrophoresis for 30 min at 120 V on a 3% agarose gel. The homozygosity of the common allele (represented by the CC genotype) was denoted via 145 and 109 bp bands, while the homozygosity of the variant allele (represented by the TT genotype) was represented by 127 and 109 bp bands. Ten microliters of the amplification product of rs7527192 were digested with one unit of Bsh1236I (BstUI) (MBI, Fermentas, Vilnius, Lithuania), incubated for 12 h at 37 °C, and separated on a 3% agarose gel. The homozygosity of the common allele (represented by the GG genotype) was denoted via 152 and 35 bp bands, while the homozygosity of the variant allele (represented by the AA genotype) was represented by a single 187 bp band, as this polymorphism destroys a restriction site for Bsh1236I.16

For rs1136410, the PCR conditions were set at 95 °C for 4 min for the denaturation, followed by 35 cycles of 94 °C for 30 s, 62 °C for 45 s and 72 °C for 45 s for the annealing step, followed by a final extension at 72 °C for 10 min. The primers that were used are as follows: forward primer 5′-TGAAGAGGCTCCGACCTG-3′ and reverse primer 5′-TGAAGGCA GAGGTTGTGC-3′. The sequential alterations for rs1136410 were determined using bidirectional sequencing. The amplicon sequences were evaluated using CLC workbench 3.6.1 (Denmark).

Haplotype analysis

Haplotypes were generated from the genotype data. The linkage disequilibrium (LD) and haplotype analyses were performed using Haploview 4.2, which uses the expectation maximization (EM) algorithm.

Data processing and analysis

The statistical analyses were performed using the Statistical Package for Social Sciences Statistical Software release 18 (SPSS Windows Version 18, SPSS, Inc., Chicago, IL, USA). The Hardy–Weinberg equilibrium (HWE) was determined in order to identify the compatibility between the patient and control groups using χ²-tests. The relationships between different parameters were evaluated using Spearman’s correlation analysis. The comparison of the frequencies and ratios between the groups was evaluated using χ²- and Fisher’s exact tests. The quantitative data containing normally distributed parameters between the groups were evaluated using Student’s t-test, while Mann–Whitney U-test was used for the remaining samples. The associations between the rs2793378, rs7527192 and rs1136410 genotypes and HT were analyzed by calculating the frequency of the variant allele (represented by the TT genotype) was denoted via 152 and 35 bp bands, while the homozygosity of the common allele (represented by the GG genotype) was represented by a single 187 bp band, as this polymorphism destroys a restriction site for Bsh1236I.16

For rs1136410, the PCR conditions were set at 95 °C for 4 min for the denaturation, followed by 35 cycles of 94 °C for 30 s, 62 °C for 45 s and 72 °C for 45 s for the annealing step, followed by a final extension at 72 °C for 10 min. The primers that were used are as follows: forward primer 5′-TGAAGAGGCTCCGACCTG-3′ and reverse primer 5′-TGAAGGCA GAGGTTGTGC-3′. The sequential alterations for rs1136410 were determined using bidirectional sequencing. The amplicon sequences were evaluated using CLC workbench 3.6.1 (Denmark).

Haplotype analysis

Haplotypes were generated from the genotype data. The linkage disequilibrium (LD) and haplotype analyses were performed using Haploview 4.2, which uses the expectation maximization (EM) algorithm.

Data processing and analysis

Haplotype analysis

Haplotypes were generated from the genotype data. The linkage disequilibrium (LD) and haplotype analyses were performed using Haploview 4.2, which uses the expectation maximization (EM) algorithm.

RESULTS

Study population

A total of 141 Hashimoto thyroiditis patients, aged between 39 and 55 years old (mean, 48.9 year), and 150 control subjects, aged between 37 and 54 years old (mean, 46.6 year), were recruited in this study. There was no significant difference between the ages of the cases and the controls.

The mean levels of thyroid stimulating hormone (TSH), AntiTPO and AntiTG antibody in the HT patients in this study were found to be 8.3 ± 6.8 μIU/ml, 806.7 ± 447.3 IU/ml and 382.7 ± 207.4 IU/ml, respectively. The TSH, AntiTG and AntiTPO antibody levels of the control subjects were 2.8 ± 1.2 μIU/ml, 65.4 ± 59.7 IU/ml and 27 ± 15.8 IU/ml, respectively. The levels of the TSH, AntiTPO and AntiTG antibodies of the HT patients were statistically higher than those of the control group, as expected (P = 0.0305, 0.0296, 0.0242, respectively).

The 141 HT patients and 150 control subjects were tested for rs2793378, rs7527192 and rs1136410. There were no statistically significant differences between the patients and controls in terms of their mean age (41.1 ± 11.7 years, P = 0.352), gender (all female, P = 0.881) and ethnicity (Turkish), indicating that the frequency matching between the groups was adequate.

Distribution of the PARP-1 SNPs in HT

The distribution of the rs2793378, rs7527192 and rs1136410 genotypes in the control group were within HWE. The distribution of the genotypes and the allele frequencies of all of the studied polymorphisms are shown in Table 1.

We found a significant association between PARP-1 rs1136410 and rs7527192 and HT. The frequency of the heterozygous TC genotype of rs1136410 was significantly greater in the controls compared to the patients (OR: 2.504, 95% CI: 1.48–4.23, P = 0.001). Moreover, the frequency of the C allele of rs1136410 was found to be statistically higher in the healthy group (OR: 1.632, 95% CI: 1.1–2.403, P = 0.013), and rs1136410 maintained its significance following Bonferroni correction. The frequency of the heterozygous genotype of rs7527192 was significantly higher in the controls (OR: 1.633, 95% CI: 1.017–2.623, P = 0.042) than in the patients. Additionally, the frequency of the A allele of rs7527192 was found to be statistically higher in the healthy group (OR: 1.492, 95% CI: 1.039–2.142, P = 0.03); although, neither the GA genotype nor the A allele of rs7527192 maintained significance following Bonferroni correction. In addition, the C allele of rs1136410 showed no significance following Bonferroni correction, and PARP-1 rs2793378 showed no protective or risk effect in HT disease. All of the results are shown in Table 1.

Haplotype analysis of the PARP-1 SNPs

We also investigated whether the three polymorphisms were in linkage disequilibrium, and any common haplotypes associated with diseases and rare haplotypes (with a frequency < 5%) were excluded from the association analyses. The most common haplotypes of the three polymorphisms, calculated by Haploview 4.2, are summarized in Table 2.

The haplotypes were generated using the three PARP-1 intragenic SNPs (rs2793378, rs7527192 and rs1136410) among the HT cases and controls, and six different haplotypes were generated (with a frequency > 5%).

Protectivity of SNP rs1136410 in Hashimoto’s thyroiditis

Koc et al.
The prevalence of the CGC haplotype was significantly higher in the controls (ratio of the cases to the controls: 0.061:0.146, \(P = 5.6 \times 10^{-3}\) (calculated as 0.05/9). \(P\) value in bold is still maintained significance after Bonferroni correction.

### Table 1. Distribution of three SNPs in PARP-1 gene in Hashimoto thyroiditis

| Genotype/allele | Cases, n (%) | Controls, n (%) | OR (95% CI) | \(P\)-value |
|----------------|-------------|----------------|-------------|------------|
| rs1136410 TT (Val/Val) | 141 (98) | 150 (77) | 1 | 0.001 |
| CC (Ala/Ala) | 141 (31) | 150 (61) | 2.504 (1.48–4.23) | 0.001 |
| T (Val) allele frequency | 227 (81) | 215 (72) | 1 | 0.579 |
| C (Ala) allele frequency | 55 (19) | 85 (28) | 1.632 (1.1–2.403) | 0.013 |
| rs2793378 CC | 141 (62) | 150 (60) | 1 | 0.752 |
| CT | 62 (44) | 65 (43) | 0.92 (0.56–1.52) | 0.725 |
| TT | 17 (12) | 25 (17) | 0.66 (0.32–1.34) | 0.247 |
| C allele frequency | 186 (66) | 185 (62) | 1 | 0.556 |
| T allele frequency | 96 (34) | 115 (38) | 0.84 (0.47–1.50) | 0.391 |
| rs7527192 GG | 141 (75) | 150 (60) | 1 | 0.027 |
| GA | 62 (44) | 81 (54) | 1.633 (1.017–2.623) | 0.042 |
| AA | 4 (3) | 9 (6) | 2.813 (0.826–9.581) | 0.087 |
| G allele frequency | 212 (75) | 201 (67) | 1 | 0.347 |
| A allele frequency | 70 (25) | 99 (33) | 1.492 (1.039–2.142) | 0.03 |

**Abbreviations:** CI, confidence intervals; OR, odds ratios. *The corresponding amino acids of each genotypes of rs1136410 polymorphism were given in parentheses. The differences resulting from the genotypes were determined by proceeding \(x^2\)-test. \(P\) value after Bonferroni correction; \(P = 5.6 \times 10^{-3}\) (calculated as 0.05/9). \(P\) value in bold is still maintained significance after Bonferroni correction.

### Table 2. The distribution of PARP-1 haplotypes

| PARP-1 haplotypes (SNPs) | Frequency | \(x^2\) | \(P\)-value |
|--------------------------|-----------|--------|------------|
| rs2793378 rs7527192 rs1136410 Total Cases Controls | | | |
| T G C | 0.488 | 0.521 | 0.406 | 2.899 | 0.0687 |
| T A T | 0.128 | 0.132 | 0.115 | 0.145 | 0.7036 |
| C G T | 0.116 | 0.121 | 0.102 | 0.182 | 0.6694 |
| T A C | 0.096 | 0.091 | 0.106 | 0.142 | 0.7068 |
| C G C | 0.085 | 0.061 | 0.146 | 0.501 | 0.0252 |
| T G T | 0.078 | 0.065 | 1.109 | 1.465 | 0.2260 |

**Abbreviation:** SNP, single-nucleotide polymorphism. \(P\) value after Bonferroni correction; \(P = 8.3 \times 10^{-3}\) (calculated as 0.05/6).

### Table 3. The distribution of rs2793378- rs7527192 combined genotypes

| rs2793378- rs7527192 combined genotypes | Cases, n | Controls, n | OR (95% CI) | \(P\)-value |
|------------------------------------------|---------|-------------|-------------|------------|
| CC/AA, CT/AA, and TT/AA combined genotypes | | | | |
| rs2793378 CC/CG | 38 | 15 | 2.956 (1.114–7.840) | 0.027 |
| CT/CG | 20 | 21 | 2.66 (1.13–6.259) | 0.023 |
| CT/GA | 32 | 17 | 1.346 (0.582–3.113) | 0.487 |
| TT/GG | 6 | 3 | 1.267 (0.28–5.73) | 0.711 |
| TT/GA | 6 | 11 | 4.644 (1.445–14.822) | 0.007 |

**Abbreviations:** CI, confidence intervals; OR, odds ratios. CC/AA, CT/AA, and TT/AA combined genotypes were excluded in the table as none observed in the subjects or the size was not enough for the statistical analyses. \(P\) value after Bonferroni correction; \(P = 8.3 \times 10^{-3}\) (calculated as 0.05/6). \(P\) value in bold is still maintained significance after Bonferroni correction.

The prevalence of the CGC haplotype was significantly higher in the controls (ratio of the cases to the controls: 0.061:0.146, \(P = 0.0252\), \(x^2 = 5.01\)), as shown in Table 2. The first marker of the CGC haplotype, the C allele, is wild type for rs2793378. The second marker of the CGC haplotype, the G allele, is wild type for rs7527192. The third marker, the C allele, is mutant for rs1136410. The difference was based on the third marker, the C allele of rs1136410, which serves as a protective factor. However, because this study was based on a small sample size, we applied a Bonferroni correction to decrease the type I error. Following Bonferroni correction, the haplotype analysis did not show any significance. Furthermore, two of the SNPs in PARP-1 (rs1136410 and rs7527192) were in strong LD (Figure 1).

Combined genotype analysis of the PARP-1 SNPs

Tables 3–5 summarize the association studies among the combined genotypes of the three SNPs and the overall risk for HT. The PARP-1 rs2793378 and rs7527192 SNPs showed statistical significance among the combined genotypes in the HT patients and controls. The combined CC/GA, CT/GG and TT/GA genotype frequencies were significantly higher in the control group versus the HT group when compared with the combined CC/GG genotype (OR: 2.956, 95% CI: 1.114–7.840, \(P = 0.027\); OR: 2.66, 95% CI: 1.13–6.259, \(P = 0.023\); OR: 4.644, 95% CI: 1.455–14.822, \(P = 0.007\), respectively). Following Bonferroni correction, only the combined TT/GA genotype remained significant and was found to be a significant protective factor against HT disease (\(P = 0.007\), as shown in Table 3.

Aside from the abovementioned results, there were no other significant differences between the multiple comparisons of rs7527192-rs1136410, and rs2793378-rs1136410 in the HT patients and control groups (Tables 4 and 5).

### DISCUSSION

Based on genome-wide association studies (GWAS) of thyroid disorders, it is clear that genetic factors are thought to be considerable determinants of thyroid function and autoimmunity.
suggested involving the capability of PARP-1 to regulate the transcription of inflammation-linked genes. Several recent publications indicate that the nuclear protein PARP-1 regulates the transcription and synthesis of inflammatory mediators.\textsuperscript{30} In addition, the relationship between PARP-1 activity and inflammation has been widely investigated, and the link with inflammation was firmly established via the pharmacological inhibition of PARP-1 activity, which allowed the attenuation of the inflammatory response.\textsuperscript{30} The inhibition of PARP-1 activity is protective in a wide range of inflammatory conditions, such as cardiovascular disease, diabetes, rheumatoid arthritis and stroke.\textsuperscript{13,31} Therefore, the PARP-1 gene may be a strong candidate based on the observations made in knockout mice, and it provides promising therapeutic approaches to inflammatory diseases using PARP-1 inhibitors.

Alternatively, PARP-1 protein concentration is controlled by the direct regulation of promoter activity. Therefore, polymorphisms within the promoter region may also affect PARP-1 activity. Multiple transcription sites, as well as 3 sets of CCAAT/TATA boxes, have been identified in the promoter region, which provide a binding site for YY1 transcription factors.\textsuperscript{26} In addition, four sequence variations have been identified in this region: rs2793378, Pol(A)\textsuperscript{n}, C1362T and rs7527192.\textsuperscript{16,20} According to Infante \textit{et al.},\textsuperscript{32} the C410T polymorphism that is found in the heterozygous state increased the risk for Parkinson’s disease, while rs7527192 heterozygosity significantly delayed the onset of the disease. In this study, we did not find any significance in regards to rs2793378.

Recently, rs2793378, rs7527192, and rs1136410 have been investigated in many inflammatory autoimmune diseases, including RA,\textsuperscript{33} asthma,\textsuperscript{34} nephritis and arthritits in SLE patients\textsuperscript{35} and Alzheimer’s disease.\textsuperscript{36,37} As described above, in our study, the heterozygous GA genotype of PARP-1 rs7527192 was found to have a protective effect on HT disease in the Turkish population. This is comparable to the results of Infante \textit{et al.}, which showed that certain promoter variations (rs2793378 and rs7527192) are associated with protection against Parkinson’s disease.\textsuperscript{34} We also previously determined that the heterozygous genotype of rs7527192 was significantly associated with susceptibility to allergic rhinitis (AR) in the Turkish population. Moreover, in this study, according to the multiple comparisons of the combined genotypes of rs2793378–rs7527192, the frequency of the TT/GA combined genotype was significantly higher in the controls versus the HT group when compared with CC/GG combined genotype. Following Bonferroni correction, only the TT/GA genotype continued to show significance as a protective factor. When the mutant form of rs2793378 and the heterozygous form of rs7527192 were combined, a significant protective effect was observed in the HT patients.

The PARP-1 promoter haplotypes have also been shown to be related to susceptibility to some chronic inflammatory diseases, such as AR, RA and celiac disease.\textsuperscript{16,33,38} The protective effect of a haplotype of the PARP-1 gene polymorphisms for Alzheimer’s disease was also detected.\textsuperscript{37} The rs2793378, rs7527192 and rs1136410 haplotypes were not associated with an increased risk for AR.\textsuperscript{33} According to Pascual \textit{et al.},\textsuperscript{16} PARP-1 haplotypes (−410, −1327, CA microsatellite repeat) play a role in susceptibility to RA in the Spanish population, whereas the rs7527192 variant did not appear to be part of this haplotype. Although the CCG haplotype was found to have a protective effect based on the C (Ala) allele of rs1136410, it did not survive Bonferroni correction.

rs1136410 is present in approximately 53%–33% of the general population.\textsuperscript{19} We previously reported that the T (Val) allele of rs1136410 is associated with an increased risk for asthma.\textsuperscript{34} Furthermore, rs1136410 was significantly associated with coronary artery disease, which is also an inflammatory process.\textsuperscript{39} Hur \textit{et al.}\textsuperscript{35} demonstrated that the nonsynonymous variant +40329T→C (V762A) was also significantly associated with an increased risk

for arthritis in Korean SLE patients. However, according to Onaran et al., rs1136410 was not associated with a risk for rheumatoid arthritis. The Val762 variants of PARP-1 rs1136410 have also been found to increase the risk of diabetic polyneuropathy in Russian type 1 diabetic patients. Additionally, we found that the heterozygous TC (Val/Ala) genotype of rs1136410 still had a protective effect on susceptibility to HT in the Turkish population even following Bonferroni correction.

PARP-1 and nuclear factor kappa B (NF-kB) have both been suggested to play a considerable role in inflammatory diseases. It has been shown that PARP-1 can act as a coactivator of NF-kB in terms of inflammatory processes in the cell. These findings provided us with new insights into the pathogenesis of different inflammatory disorders, such as HT. We previously reported that the frequency of the deletion allele of NF-kB rs28362491 that accompanies high interleukin-6 (IL-6) levels was significant in an HT patient group. This study is a follow-up to our previous research.

Moreover, it should be kept in mind that the small sample size, which may have influenced the statistical power of our analyses, may be considered to be a limitation of this study. Although a study with low statistical power has a reduced chance of detecting a true effect, case–control studies with small sample sizes are still widely used, and they can be used to assess previously identified candidate regions under selection and more precisely determine the selection targets. Nonetheless, a larger sample size and replication study will provide reassurance for further studies.

We carried out single and combined genotype and haplotype analyses to evaluate the SNPs rs2793378, rs7527192 and rs1136410 in a population-based case–control study. To the best of our knowledge, there are no published studies exploring the associations between these PARP-1 variants and HT disease. We found that the heterozygous genotype of rs1136410 had a significantly decreased risk for HT disease in a group of women from the Turkish population. Molecular heterosis may be present in 50% of all of the gene associations, and it has also been found to be related to elevated IL-6, IL-1 (rs7527192, rs28362491 and rs696) were recently reported for variations in the PARP-1 gene. 32,34 The biological meaning of the ‘protective’ effect of the heterozygous genotype of rs1136410 toward HT cannot be easily explained by the existing observations regarding the PARP-1 SNPs. However, it has been demonstrated that the modulation of cytokine production by various stimulators is more strongly affected by the heterozygous variants of several SNPs in various genes than by the homozygous variant. For example, the heterozygous genotypes of four SNPs (rs7527192, rs2793378, rs28362491 and rs696) were recently found to be related to elevated IL-6, IL-1β and tumor necrosis factor alpha (TNF-α) cytokine production in Graves’ disease in a Turkish population. In addition, the 4257GA heterozygous genotype was found to be associated with higher IL-13 levels in asthmatics. A relationship between the heterozygous -137 G/C genotype in the IL-18 gene with elevated IL-18 serum levels and bladder cancer risk was detected in a North Indian population. Moreover, the T cells from heterozygous TC-carrier rheumatoid arthritis patients produced higher TNF-α, IL-17, and interferon-γ when compared with patients carrying the TT-TC carrier type. All of these studies show meaningful associations between the heterozygous genotype and increasing cytokine production.

PARP-1 is required for the activation of several transcription factors via the inflammation of several mediators. It has been speculated that a different PARP-1 binding and activation mechanism because of the heterozygous genotype of rs1136410 may affect the expression of the genes involved in the inflammatory response, perhaps via an altered inflammatory pathway. Therefore, this polymorphism may confer a protective effect against HT. However, this hypothesis still requires further investigation.

In summary, it is possible that the interactions of variants of the PARP-1 gene have key roles in organizing the various changes that occur during the inflammatory response in HT disease. However, replication studies or additional functional studies with a larger sample size are required to confirm the putative protective role of these PARP-1 gene variants. More precisely, larger trials and replication studies that include different ethnic groups are highly recommended to properly define the relationship between the PARP-1 polymorphisms (especially rs1136410 TC) and the development of HT, as well as the prognosis of the disease.

ACKNOWLEDGEMENTS

This study was supported by a grant from the Scientific Research Projects Coordination Unit of Istanbul University (Project no. 4055).

AUTHOR CONTRIBUTIONS

All of the authors read and approved the final version of the manuscript. AK collected and isolated the DNA samples, performed the genotyping and statistical analyses of the data and drafted the manuscript. MAS and FK also performed the genotyping studies. BB helped to analyze the statistical data and provided critical revisions. OC, MN and ET collected the blood samples from the patients and controls. IO and GKS designed the study and provided advice. All of the authors discussed the results and commented on the manuscript.

COMPETING INTERESTS

The authors declare no conflict of interest.
