SUPPLEMENTARY FIGURES

Supplementary Figure 1. Pearson correlations between methylation clocks and with chronological age in samples from healthy pediatric patients: (A) blood, (B) buccal, and (C) saliva.

Supplementary Figure 2. Boxplots of residuals of the regression of methylation age to chronological age for samples from healthy children: (A) blood, (B) buccal, (C) saliva, and (D) brain.
Supplementary Figure 3. (A) Scatter plots of age estimates from seven clocks (x-axis), against estimated proportions of six blood cell types, adjusted for chronological age: (CD8+) T cells (CD8T), helper (CD4+) T (CD4t), natural killer (NK), B cells (Bcell), monocytes (Mono) and granulocytes (Gran). (B) Pearson correlations of data from (A), where correlations with adjusted (Benjamini-Hochberg) p-values < 0.05 are displayed.

Supplementary Figure 4. Boxplots of age acceleration for two sample types for the adult samples. Samples include unsorted brain tissue, and FACS sorted cells that are negative (NeuN-) for a neuronal marker. For the Skin and blood methylation clock, the NeuN- cells have significantly (adj. p = 0.038) lower age acceleration than unsorted brain cells. FACS sorted cells positive for neuronal marker (NeuN+) are not included here as there were only one adult patient with methylation data for NeuN+ cells.
