Abstract: Fertilizing in a balanced way promotes crop quality and soil health as well as crop growth and production. This study was conducted to determine the best approach of fertilization for jute production in Bangladesh in the experimental fields under Bangladesh Jute Research Institute. A randomized block design with three replications was used to set up the experiment, which included ten fertilizer treatments. The treatments were: T1 – control (no fertilization), T2 – 50:10:30:20 kg N:P:K:S ha⁻¹, T3 – 100:10:30:20 kg N:P:K:S ha⁻¹, T4 – 150:10:30:20 kg N:P:K:S ha⁻¹, T5 – 100:5:30:20 kg N:P:K:S ha⁻¹, T6 – 100:15:30:20 kg N:P:K:S ha⁻¹, T7 – 100:10:60:20 kg N:P:K:S ha⁻¹, T8 – 100:10:90:20 kg N:P:K:S ha⁻¹, T9 – 100:10:60:10 kg N:P:K:S ha⁻¹, T10 – 100:10:90:30 kg N:P:K:S ha⁻¹. The purpose of this study was to determine what nutrition BJRI Tossa Pat-8 need for optimal growth and yield. The results indicated significant effect on yield and yield contributing characters over control with different NPK and S levels of BJRI Tossa Pat-8. The highest fibre and stick yield were obtained by the combination dose of N100 Kg ha⁻¹ with 10:60:20 kg P:K:S ha⁻¹. The plant height, base diameter also found highest with the same treatment of fertilizer combination. Therefore this combination (T7 – 100:10:60:20 kg N: P: K: S ha⁻¹) seemed to be optimum for good growth and high potential for BJRI Tossa Pat-8 for fibre production in Bangladesh.

Keywords: Fibre Yield, Growth, Nutrient, BJRI Tossa Pat-8

1. Introduction

Jute, an important and the largest natural fiber crop belonging to the genus Corchorus, family Tiliaceae, is an eco-friendly and the major cash crop of Bangladesh. Jute fiber is produced mainly from white jute (C. capsularis), and tossa jute (C. olitorius). Bangladesh and India produce over 92% of the total jute fibre of the world. The major jute growing areas in Bangladesh are Faridpur, Jessore, Manikganj, Kishoreganj, Mymensingh and Rangpur regions. It is one of the most popular fibre crops in every districts of Bangladesh. Corchorus olitorius is mainly known for its fibre product. Jute is highly responsive to chemical fertilizer and organic manures. Use of chemical fertilizers has positive as well as negative effect on soil microbial population and their activities. Soil organisms act as primary driving agents. The application of essential plant nutrients in optimum quantity and right proportion, through correct method and time of application is the key to increased and sustained crop production [1]. This over-fertilization by farmers, driven by the desire for higher yields, does not always contribute to high yield but it has recently become a common practice for farmers in China nonetheless [2]. Unfortunately, over-fertilization decreases the efficiency of nutrient use and causes a series of economic and environmental problems [3]. However, balanced mineral fertilizer inputs have played an important role in increasing the rice and oilseed rape yields. Therefore, it is very important to apply fertilizers in an efficient way to minimize loss and to improve the nutrient use efficiency [4]. Mineral nutrition of plants is important for controlling physiological and biochemical processes of plants. Its deficiency may lead to changes in these processes and disturbed plant growth and yield [5]. Nitrogen plays a key role in agriculture by increasing of crop yield [6]. Optimum, rate of N increases photosynthetic processes, leaf area production, leaf area duration as well as net assimilation rate [7]. Phosphorus deficiency is invariably a common crop growth and yield-limiting factor in unfertilized soils, especially in soils high in Calcium carbonate, which reduces solubility [8]. Potassium plays a vital role in the
plants especially in cell metabolism, activate enzyme activity and enhanced the plant growth and crop quality [9-11]. Sulfur is an essential nutrient for plant growth and metabolism. Responses in crop growth and yield to the addition of S have been reported [12]. Therefore, present study is aimed to determine the nutritional requirement of the BJRI Tossa pat-8 for fibre production.

2. Materials and Methods

The experiment was conducted in the experimental field under Bangladesh Jute Research Institute. The experiment was laid out in randomized complete block design with three replications. A total 10 treatment combinations along with a control were distributed randomly in each plot as one replication (Table 1). The dimension of unit plots was 3.1 m × 3.1 m having 1 m space between the plots, blocks and around the field. There was 20 cm deep drain around each block and plot. Each replication was divided into 10 unit plots and the total land required of 13.3 m × 42 m. At the beginning of the experiment, the land was well prepared and fertilizers were applied as per treatment.

| Tr. N-P-K-S- kg/ha | Tr. N-P-K-S kg/ha |
|-------------------|-------------------|
| T1: 00-00-00-00   | Tc: 100-15-30-20  |
| T2: 50-10-30-20   | Tc: 100-10-60-20  |
| T3: 100-10-30-20  | Tc: 100-10-90-20  |
| T4: 150-10-30-20  | Tc: 100-10-60-10  |
| T5: 100-5-30-20   | Tc: 100-10-90-30  |

Required amounts of N, P, K, S fertilizers were applied in the form of urea, TSP, MoP and gypsum. Half of Urea was applied at sowing and the rest half was top dressed at 45 days after sowing while all other fertilizers were applied at the time of sowing. Jute seeds were broadcasted at the rate of 8kg/ha. All cultural operations were done as and when necessary. The crop was harvested when 80% of the plants showed the sign of maturity. After shedding of leaves, the bundles were steeped plot-wise in pond water for 15-20 days for retting and fiber was extracted. At harvesting time, six plants were selected at random from each plot and tagged in the field to note plant height (PH), base diameter (BD), green yield (GY), fiber yield (FY) and stick yield (SY). Statistical analysis was done [13].

3. Results and Discussion

To introduce combination treatments, the experiment used four nitrogen levels (0, 50, 100, and 150 kg/ha) in conjunction with other nutrients. Plant growth and yield were altered by nitrogen levels compared to the control. Nitrogen @ 100 Kg/ha treatment (T7) produced significant highest fibre yield. But highest dose of N 150Kg/ha showed significantly lower yield than the dose N 100kg/ha. The growth indicator i.e. plant height and base diameter found significantly highest by N 100Kg/ha and treatment T4 where N 150Kg/ha used showed statistically lower base diameter to treatment T7 where used N 100Kg/ha. From the results, it was observed that 100 kg N/ha may be an adequate amount to produce BJRI Tossa Pat-8.

4. Conclusion

The use of combined chemical fertilizers had a considerable favorable impact on all yield contributing metrics as well as yield. Finally, we can conclude that combined dose of NPK and S 100-10-60-20 kg/ha is appropriate for the cultivation of BJRI Tossa Pat-8. The study evolved a technology which ultimately recommendation of fertilizer (NPK & S 100-10-60-20 Kg/ha) for BJRI Tossa Pat-8.

Conflict of Interest

The authors declare no conflict of interest exists.
