Abstract 
This paper proposes to solve the bottleneck of finding training data for word sense disambiguation (WSD) in the domain of web queries, where a complete set of ambiguous word senses are unknown. In this paper, we present a combination of active learning and semi-supervised learning method to treat the case when positive examples, which have an expected word sense in web search result, are only given. The novelty of our approach is to use "pseudo negative examples" with reliable confidence score estimated by a classifier trained with positive and unlabeled examples. We show experimentally that our proposed method achieves close enough WSD accuracy to the method with the manually prepared negative examples in several Japanese Web search data. 

1 Introduction 
In Web mining for sentiment or reputation analysis, it is important for reliable analysis to extract large amount of texts about certain products, shops, or persons with high accuracy. When retrieving texts from Web archive, we often suffer from word sense ambiguity and WSD system is indispensable. For instance, when we try to analyze reputation of "Loft", a name of variety store chain in Japan, we found that simple text search retrieved many unrelated texts which contain "Loft" with different senses such as an attic room, an angle of golf club face, a movie title, a name of a club with live music and so on. The words in Web search queries are often proper nouns. Then it is not trivial to discriminate these senses especially for the language like Japanese whose proper nouns are not capitalized. 
To train WSD systems we need a large amount of positive and negative examples. In the real Web mining application, how to acquire training data for a various target of analysis has become a major hurdle to use supervised WSD. Fortunately, it is not so difficult to create positive examples. We can retrieve positive examples from Web archive with high precision (but low recall) by manually augmenting queries with hypernyms or semantically related words (e.g., "Loft AND shop" or "Loft AND stationary"). 
On the other hand, it is often costly to create negative examples. In principle, we can create negative examples in the same way as we did to create positive ones. The problem is, however, that we are not sure of most of the senses of a target word. Because target words are often proper nouns, their word senses are rarely listed in hand-crafted lexicon. In addition, since the Web is huge and contains heterogeneous domains, we often find a large number of unexpected senses. For example, all the authors did not know the music club meaning of Loft. As the result, we often had to spend much time to find such unexpected meaning of target words. 
This situation motivated us to study active learning for WSD starting with only positive examples. The previous techniques (Chan and Ng, 2007; Chen et al. 2006) require balanced positive and negative examples to estimate the score. In our problem setting, however, we have no negative examples at the initial stage. To tackle this problem, we propose a method of active learning for WSD with pseudo negative examples, which are selected from unlabeled data by a classifier trained with positive and unlabeled examples. McCallum and Nigam (1998) combined active learning and semi-supervised learning technique
by using EM with unlabeled data integrated into active learning, but it did not treat our problem setting where only positive examples are given. The construction of this paper is as follows; Section 2 describes a proposed learning algorithm. Section 3 shows the experimental results.

2 Learning Starting with Positive and Unlabeled Examples for WSD

We treat WSD problem as binary classification where desired texts are positive examples and other texts are negative examples. This setting is practical, because ambiguous senses other than the expected sense are difficult to know and are no concern in most Web mining applications.

2.1 Classifier

For our experiment, we use naive Bayes classifiers as learning algorithm. In performing WSD, the sense “s” is assigned to an example characterized with the probability of linguistic features \( f_1, ..., f_n \) so as to maximize:

\[
p(s) \prod_{j=1}^{n} p(f_i | s) = \max
\]

The sense \( s \) is positive when it is the target meaning in Web mining application, otherwise \( s \) is negative. We use the following typical linguistic features for Japanese sentence analysis, (a) Word feature within sentences, (b) Preceding word feature within bunsetsu (Japanese base phrase), (c) Backward word feature within bunsetsu, (d) Modifier bunsetsu feature and (e) Modifiee bunsetsu feature.

Using naive Bayes classifier, we can estimate the confidence score \( c(d, s) \) that the sense of a word instance “d”, whose features are \( f_1, f_2, ..., f_n \), is predicted sense “s”:

\[
c(d, s) = \log p(s) + \sum_{j=1}^{n} \log p(f_i | s)
\]

2.2 Proposed Algorithm

At the beginning of our algorithm, the system is provided with positive examples and unlabeled examples. The positive examples are collected by full text queries with hypernymms or semantically related words.

First we select positive dataset \( P \) from initial dataset by manually augmenting full text query.

At each iteration of active learning, we select pseudo negative dataset \( N_p \) (Figure 1 line 15). In selecting pseudo negative dataset, we predict word sense of each unlabeled example using the naive Bayes classifier with all the unlabeled examples as negative examples (Figure 2). In detail, if the prediction score (equation(3)) is more than \( \epsilon \), which means the example is very likely to be negative, it is considered as the pseudo negative example (Figure 2 line 10-12).

\[
c(d, \text{psdNeg}) = c(d, \text{neg}) - c(d, \text{pos})
\]

![Figure 1: A combination of active learning and semi-supervised learning starting with positive and unlabeled examples](image-url)
example is provided by human and added to the positive dataset P or the negative dataset N according to the sense of d.

The above steps are repeated until dataset reaches the predefined desirable size.

01 foreach d □ ( T – P – N )
02 classify d by WSD system □ (P, T-P)
03 c(d, pos) □ the confidence score that d is
04 predicted as positive defined in equation (2)
05 c(d, neg) □ the confidence score that d is
06 predicted as negative defined in equation (2)
07 c(d, psdNeg) = c(d, neg) - c(d, pos)
08 (the confidence score that d is
09 predicted as pseudo negative)
10 PN □ d □ ( T – P – N ) | s(d) = neg □
11 c(d, psdNeg) □ □ }
12 (PN is pseudo negative dataset )
13 end

Figure 2: Selection of pseudo negative examples

3 Experimental Results

3.1 Data and Condition of Experiments

We select several example data sets from Japanese blog data crawled from Web. Table 1 shows the ambiguous words and each ambiguous senses.

| Word       | Positive sense         | Other ambiguous senses                                                                 |
|------------|------------------------|--------------------------------------------------------------------------------------|
| Wega       | product name (TV)      | Las Vegas, football team name, nickname, star, horse race, Baccarat glass, atelier, wine, game, music |
| Loft       | store name             | attic room, angle of golf club face, club with live music, movie                      |
| Honda      | personal name (football player) | Personal names (actress, artists, other football players, etc.) hardware store, car company name |
| Tsubaki    | product name (shampoo) | flower name, kimono, horse race, camellia ingredient, shop name                        |

Table 1: Selected examples for evaluation

Table 2 shows the ambiguous words, the number of its senses, the number of its data instances, the number of feature, and the percentage of positive sense instances for each data set.

| Word | No. of senses | No. of instances | No. of features | Percentage of positive sense |
|------|---------------|------------------|-----------------|-----------------------------|
| Wega | 11            | 5,372            | 164,617         | 31.1%                       |
| Loft | 5             | 1,582            | 38,491          | 39.4%                       |
| Honda| 25            | 2,100            | 65,687          | 21.2%                       |
| Tsubaki | 6        | 2,022            | 47,629          | 40.2%                       |

Table 2: Selected examples for evaluation

Figure 3: Average active learning process

B-clustering is a standard unsupervised WSD, a clustering using naive Bayes classifier learned with two cluster numbers via EM algorithm. The given number of the clusters are two, negative and positive datasets.

M-clustering is a variant of b-clustering where the given number of clusters are each number of ambiguous word senses in table 2.

Human labeling, abbreviated as human, is an active learning approach starting with human labeled negative examples. The number of hu-
man labeled negative examples in initial training data is the same as that of positive examples in figure 3. Human labeling is considered to be the upper accuracy in the variants of selecting pseudo negative examples.

Random sampling with EM, abbreviated as with-EM, is the variant approach where \( d_{\text{min}} \) in line 26 of figure 1 is randomly selected without using confidence score.

Uncertainty sampling without EM (Takayama et al. 2009), abbreviated as without-EM, is a variant approach where \( \bar{d}_{\text{EM}} (P, N+N_p, T-N-P) \) in line 18 of figure 1 is replaced by \( \bar{d} (P, N+N_p) \).

Uncertainty Sampling with EM, abbreviated as uncertain, is a proposed method described in figure 1.

The accuracy of the proposed approach with-EM is gradually increasing according to the percentage of added hand labeled examples.

The initial accuracy of with-EM, which means the accuracy with no hand labeled negative examples, is the best score 81.4% except for that of human. The initial WSD accuracy of with-EM is 23.4 and 4.2 percentage points higher than those of b-clustering (58.0%) and m-clustering (77.2%), respectively. This result shows that the proposed selecting method of pseudo negative examples is effective.

The initial WSD accuracy of with-EM is 1.3 percentage points higher than that of without-EM (80.1%). This result suggests semi-supervised learning using unlabeled examples is effective.

The accuracies of with-EM, random and without-EM are gradually increasing according to the percentage of added hand labeled examples and catch up that of human and converge at 30 percentage added points. This result suggests that our proposed approach can reduce the labor cost of assigning correct labels.

The curve with-EM are slightly upper than the curve random at the initial stage of active learning. At 20 percentage added point, the accuracy with-EM is 87.0 %, 1.1 percentage points higher than that of random (85.9%). This result suggests that the effectiveness of proposed uncertainty sampling method is not remarkable depending on the word distribution of target data.

There is really not much difference between the curve with-EM and without-EM. As a classifies to use the score for sampling examples in adaptation iterations, it is indifferent whether with-EM or without-EM.

Larger evaluation is the future issue to confirm if the above results could be generalized beyond the above four examples used as proper nouns.

3.3 Dependency on Threshold Value \( \tau \)

Figure 4 shows the average WSD accuracies of with-EM at 0, 25, 50 and 75 as the values of \( \tau \). The each curve represents our proposed algorithm with threshold value \( \tau \) in the parenthesis. The accuracy in the case of \( \tau = 75 \) is higher than that of \( \tau = 50 \) over 20 percentage data added point.

This result suggests that as the number of hand labeled negative examples increasing, \( \tau \) should be gradually decreasing, that is, the number of pseudo negative examples should be decreasing. Because, if sufficient number of hand labeled negative examples exist, a classifier does not need pseudo negative examples. The control of \( \tau \) depending on the number of hand labeled examples during active learning iterations is a future issue.
