Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Use of virtual care in ophthalmology in Ontario, Canada in 2020 during the COVID-19 pandemic

Ya-Ping Jin,*†‡ Mayilee Canizares,* Sherif El-Defrawy,* Wongel Bogale,† Yvonne M. Buys*

Objective: To investigate the use and trends of virtual care in ophthalmology and examine associated factors in a universal health care system during the COVID-19 pandemic in 2020.

Design: Cross-sectional study.

Participants: Ontarians eligible for the Ontario Health Insurance Plan.

Methods: We used physician billing data from 2017–2020 to describe the use of virtual versus in-person care. We used logistic regression to examine factors associated with virtual care use.

Results: The uptake of ophthalmic virtual visits increased immediately following the government’s directive to ramp down clinic activities and institution of a new virtual fee code (17.6%), peaked 2 weeks later (55.8%), and decreased immediately after the directive was lifted (24.2%). In March–December 2020, virtual visits were higher in female (11.6%) versus male (10.3%) patients and in patients <20 years of age (16.4%) and 20–39 years of age (12.3%) versus those aged 40–64 years (10.8%) and 65+ years (10.6%). Patients residing in the poorest/poorer neighbourhoods (10.9%) had similar use as their counterparts (11.1%). Patients with an acute infectious disease (14.2%) or nonurgent diagnosis (16.2%) had the highest use. Those with retinal disease had the lowest use (4.2%). Female ophthalmologists (15.4%) provided virtual care more often than male ophthalmologists (9.9%). Ophthalmologists aged 60–69 years (13.1%) provided virtual care more often than any other age groups (<40 years: 11.3%; 40–49 years: 11.0%; 50–59 years: 10.0%; and 70+ years: 7.7%). Multiple logistic regression models revealed similar results.

Conclusion: Virtual care in ophthalmology increased significantly during the initial phase of the pandemic and decreased thereafter. There were significant variations in virtual care use by patient and ophthalmologist characteristics.

To limit the spread of the COVID-19 and maintain patient care, virtual visits were encouraged in many jurisdictions. Consequently, rapid adoption of digital tools and technologies for health care delivery has grown exponentially worldwide during the pandemic.1,2 Several terms such as telehealth and telemedicine were used in the literature to name medical services provided through digital tools and technologies. In this study, we used virtual care to refer to “any interaction between patients and/or members of their circle of care, occurring remotely, using any forms of communication or information technologies, with the aim of facilitating or maximizing the quality and effectiveness of patient care,” as defined in the Virtual Health Symposium.3

A recent U.S. study showed striking variation among medical specialties in the use of virtual care, with the lowest use in ophthalmology.4 In ophthalmology, information is limited regarding which patients and ophthalmologists adopted virtual care more often and if the initial surge in virtual care services was sustained during the pandemic period. In the United States, a report suggested that during the pandemic marginalized populations were less likely to receive ophthalmic virtual care.5 Socioeconomic disparities in eye care thus were widened during the pandemic.5 It is unknown whether this reported disparity holds true in Canada with a universal publicly funded health system.

Using population-based health administrative data, we describe the use and trends of virtual care in ophthalmology and examine factors associated with the use of ophthalmic virtual care in Ontario during the COVID-19 pandemic in 2020.

Materials and Methods

In Canada, medically necessary services are universally covered for all residents by publicly funded health insurance administered at the provincial level. In Ontario, the largest province in Canada by population (>14.7 million in 2020), ophthalmologists submit claims to the Ontario Health Insurance Plan (OHIP) for payment of insured services, including in-person and virtual visits.

Data sources

Study data were obtained from 3 population-based databases housed at ICES from 2017 to 2020: OHIP physician billing database, ICES Physician Database and Registered
Persons Database.7 The OHIP database provided patient—physician encounter information (e.g., date of visit, diagnosis, fee/service code). The ICES Physician Database furnished physician-related information (e.g., physician sex, age, and specialty). The Registered Persons Database contained demographic information (e.g., age, sex, and neighbourhood income quintiles) for OHIP-insured Ontarians. There were 5 health regions (Toronto, Central, North, West, and East) in Ontario in 20209 (Fig. 1). Database linkages were done using encrypted unique health card numbers in a protected environment by ICES analysts. Aggregated data were provided for analyses. This study was approved by the Research Ethics Board at the University of Toronto.

Virtual visits and ophthalmologists

Prior to the COVID-19 pandemic, physician services provided electronically were coded with a “U” prefix,7 which had rules and restrictions regulating when they could be used.7 In response to the COVID-19 pandemic, on March 14, 2020, the Ontario Ministry of Health introduced new temporary billing codes for physician encounters with insured persons by telephone or video.10 Specifically, the fee code “K083” was used by ophthalmologists to claim services provided by telephone or video.10 The new “K” code had few restrictions on use. The payment claimed for virtual services is determined by the number of units. To determine the number of units, the in-person fee listed in the Schedule of Benefits for Physician Services for the service provided is rounded to the nearest $5 and then divided by 5.10 For example, a partial assessment (A234) with a listed fee of $28.95 in the Schedule of Benefits for Physician Services would be 6 units ($28.95 rounded to the nearest $5, i.e., $30, divided by 5 represents 6 units) for virtual services10,11 Similarly, a specific assessment (A233) with a listed fee of $57.70 would be 12 units, and a consult (A235 or A253) with a fee of $82.20 would be 16 units.11 An ophthalmic virtual visit should never be billed for less than 6 units and is very unlikely to qualify for more than 16 units. Ophthalmologists were identified from specialty code.

Ophthalmology diagnostic groups

We grouped ophthalmic diseases into 8 categories: acute infectious disease (e.g., conjunctivitis), urgent eye condition (e.g., superficial injury of eye), cataract, glaucoma, diabetes, retinal disease, nonurgent eye conditions (e.g., amblyopia), and other unspecified eye conditions (i.e., diseases not included in any of the preceding groups). Details of the classification are presented in Appendix A (available online).
Surgery cannot be done virtually, so these services were excluded.

**Statistical analysis**

Descriptive data on the number and percentage of virtual encounters at the population level in Ontario were calculated yearly from 2017 to 2020. The percentage of virtual encounters was computed as the number of virtual visits (numerator) divided by the total number of virtual and in-person visits (denominator). To better understand the trend in use of virtual care during the 2020 pandemic period, we calculated the weekly use of virtual care, with week 1 defined as the week starting on March 16, 2020. We considered the use of virtual care from March 16, 2020, to December 31, 2020, as the study event, and patient characteristics (i.e., age, sex, neighbourhood income quintile, health region of residence) and ophthalmologist characteristics (i.e., age and sex) as the independent factors. These 6 variables were put into a logistic regression model to assess patients’ and ophthalmologists’ factors associated with virtual versus in-person visits and adjust for the confounding effects of covariates. Except for the independent variable in question (e.g., patient sex), all other 5 variables in the model served as covariates. These 6 variables were chosen because they were available in ICES databases, they were potential confounding factors and not in the causal pathway to virtual care, and their associated frequency data met ICES data-release rules. Results of these models are presented as adjusted odds ratios (aORs) with 95% CIs.

**Results**

The total number of ophthalmology assessments or consults (i.e., including in-person and virtual visits) was 2.51 million in 2017, 2.54 million in 2018, 2.53 million in 2019, and 2.02 million in 2020 (20% reduction compared with 2019). Considering virtual visits only, there were 1733 in 2017, 2007 in 2018, 2610 in 2019, and 167,633 in 2020. The percentage of virtual care use was 0.07% in 2017, 0.08% in 2018, 0.10% in 2019, and 8.31% in 2020.

In 2020, the weekly uptake of virtual visits increased immediately during the week of the Ontario government’s directive to ramp down clinic activities and institution of a new virtual fee code (17.6%, week of March 16, 2020), peaked 2 weeks later (55.8%, week of March 30, 2020), and decreased immediately after the directive was lifted (24.2%, week of May 25, 2020) (Fig. 2A). The use of virtual care was further reduced to 8%–16% in June 2020 and to 5%–10% in July–December 2020. By health region, the level of virtual care use was lowest in the West region versus any other region during the entire study period (Fig. 2B).

Figure 3 shows that during the 2020 pandemic period (March 16–December 31, 2020), higher uptake of virtual care was seen in female versus male patients and in patients <20 and 20–39 years of age versus those aged 40–64 and 65+ years. Patients residing in the poorest/poorer neighbourhoods used virtual care similarly to their counterparts (10.9% vs 11.1%). Patients with

---

**Fig. 2—** Weekly use (%) of virtual and in-person visits to ophthalmologists in 2020 in Ontario (A) and weekly use of virtual visits to ophthalmologists by health regions in 2020 in Ontario (B).
nonurgent eye diagnoses (16.2%), acute infectious disease (14.2%), or glaucoma (13.3%) had the highest use of virtual care. Those with a retinal disease diagnosis (4.2%) used virtual care the lowest.

Figure 4 shows that female ophthalmologists were 1.6 times more likely to provide virtual care than male ophthalmologists, and ophthalmologists aged 60–69 years were more likely to provide virtual care than those in any other age group.

Figure 5 shows the percentage of virtual care units claimed among all virtual care services stratified by ophthalmologist sex. For both sexes, about half (48%) of virtual services were billed as 6 units (partial assessment); an additional 30% and 16% were billed as 12 units (specific assessment) and 16 units (consult), respectively. In addition, about 2% of virtual care services were billed for 1–5 units and 1% for 17+ units (with the maximum number of units for one visit being 80).

Results of logistic regression analyses are shown in Figure 6. Significantly higher odds of virtual care use were found in female (aOR = 1.13) versus male patients, in patients <20 years of age (aOR = 1.57), and 20–39 years of age (aOR = 1.17) versus 65+ years of age; in patients residing in the Central (aOR = 1.37), East (aOR = 1.52), and North (aOR = 1.13) regions versus those in the Toronto region, and in female (aOR = 1.65) versus male ophthalmologists. Compared with ophthalmologists aged 60–69 years, those in other age groups were less likely to use virtual care.

Discussion

To mitigate the disruption of health care services from the COVID-19 pandemic and to protect both patients and health care providers, virtual care seems an ideal option. Using physician billing data from a single government payer, this study reports that the use of virtual care by ophthalmologists in Ontario had an 80-fold increase in the pandemic year 2020, from 0.07%–0.10% before COVID-19 to 8.31% in 2020. The increased use of virtual care in 2020 fluctuated closely with the government’s directive on health care service delivery and institution of a new virtual care billing code. After the first wave of the pandemic, virtual care represented 5%–10% of visits, much higher than the prepandemic level (0.07%–0.10%). Users of ophthalmic virtual care were more likely to be female patients, patients younger than 40 years of age, patients with an acute infectious disease or nonurgent diagnosis, patients residing in a health region other than the West, female ophthalmologists, and ophthalmologists aged 60–69 years.

The increased use of virtual care during the pandemic may be attributed to multiple factors, including social distancing mandates, government’s institution of a new virtual care billing code, the availability and affordability of electronic devices such as widely available personal telephones and home computers, and patient convenience. Decreased use of ophthalmic virtual care following the lifting of the government’s directive after the first pandemic wave suggests that ophthalmologic assessments require an examination of
the visual system that in most cases cannot be done virtually. The need of specialized equipment and use of technology for the diagnosis and management of most ophthalmic conditions require an in-person assessment. Thus, if the option of in-person care is possible, both patients and ophthalmologists will choose in-person services. This explanation is consistent with the report that among various specialties, ophthalmology has the lowest number of telehealth users. The higher use of virtual care for patients with an acute eye infectious disease (e.g., conjunctivitis) and the lower use of virtual care for patients with retinal disease further support this explanation. Many acute eye infectious diseases are superficial and can be diagnosed without requiring specialized equipment or technology, whereas

Fig. 4—Use (%) of virtual care during the pandemic period in 2020 (March 16–December 31) by ophthalmologist characteristics in Ontario.
retinal disease usually requires an in-person examination in order to view the back of the eye, which cannot be done via virtual tools at the present time. Hopefully, more research efforts and technology development in the future will make virtual examinations of the visual system possible so that more ophthalmic patients can be benefit from virtual care.

In the United States, worsened disparity in access to virtual care during the pandemic was reported. This finding, however, was not evident in our study. Many factors, including the universal health care in Canada and the population-based nature of this study, may contribute to the different conclusions. However, in either privatized health
care in the United States or universal health care in Canada, female eye patients used virtual care more often than male eye patients. Similarly, when looking at all patient visits, female ophthalmologists used virtual care more frequently than male ophthalmologists (15.4% vs 9.9%; Fig. 4). These findings are in agreement with a report that females have followed preventive practices of physical distancing, mask wearing, and maintaining hygiene to a greater degree than males.19 Young patients were more likely to use virtual care, which is expected because young people are reported to be more savvy with technology,20 a key requirement for virtual care. However, we found that young ophthalmologists used virtual care less often than ophthalmologists aged 60–69 years (Fig. 4). This unexpected result may demonstrate different concerns and priorities and adherence to preventive health practices by ophthalmologists of different ages. Further studies are needed to understand the reasons why young ophthalmologists used less virtual care.

Major limitations of this study include that billing codes do not distinguish between video- and telephone-based services. In the United States, 92% of the ophthalmic virtual services are video based.5 We do not know if this is true in Ontario. Second, information is not available regarding patient ethnicity, levels of education and income, and spoken language; these are factors frequently discussed in the U.S. studies. However, the available information on neighbourhood income level in this study may have taken into account the effects of education and income on the use of virtual care, which reveal a different conclusion from the U.S. reports.5,18 Third, studies are needed to understand outcomes of virtual versus in-person care and patients’ and physicians’ views and perceptions of the benefits and challenges of delivering care virtually. Fourth, the new virtual billing code introduced during the pandemic, which has fewer restrictions than the virtual billing codes pre-COVID-19, limits comparisons of virtual care use in 2020 versus 2017–2019. However, the new virtual billing code has been validated since the onset of the pandemic, making comparisons of virtual care use during the pandemic period valid. Fifth, our analysis included data up to December 2020 only. Repeated shutdowns and reopenings in Ontario because of the different waves of COVID-19 call for an analysis with updated data to see how ophthalmic virtual care evolved in the various waves of COVID-19. Lastly, Ontario’s quick response to institute a new virtual billing code to cope with the COVID-19 pandemic was associated with some misunderstanding in how the new billing code should be used by physicians. We found both over- (units 17+) and underclaims (units 1–5) in the number of units for a single virtual encounter. These incorrect billings are harmful to both ophthalmologists (underpayment for units 1–5) and government (potential overpayment for units 17+). We communicated this billing issue to the Ministry of Health, which resulted in a bulletin to Ontario physicians further clarifying how the new virtual code should be billed.21 These incorrect billings, however, do not affect our results on the use of virtual care because the number of units billed affects the financial payment but not the number of virtual encounters.
In conclusion, the COVID-19 pandemic has expanded the use of virtual care in 2020 and onward. In response to the government’s directive and institution of a new virtual billing code, the use of virtual care in ophthalmology in Ontario increased significantly during the initial phase of the pandemic in 2020 and decreased immediately during the week the directive was lifted. This suggests that in-person care is preferred in ophthalmology. Both patients and ophthalmologists have subgroups associated with a higher level of virtual care use, reflecting different concerns and adherence to preventive health practices associated with the COVID-19 pandemic. Increased disparity in the use of virtual care observed in studies in the United States\textsuperscript{5,18} was not evident in this study based in Ontario.
