Synthesis of spiromidazopyridineoxindole, spiropyridopyrimidineoxindole and spiropyridodiazepineoxindole derivatives based on heterocyclic ketene aminals via a four-component reaction†

Fatemeh Rahimi, Mohammad Bayat* and Hajar Hosseini

Here, we have described the synthesis of novel spiropyridineoxindole derivatives containing a pyridone ring via a four-component reaction between various diamines, 1,1-bis(methylthio)-2-nitroethylene, isatin derivatives and Meldrum’s acid in the presence of p-toluenesulfonic acid. This protocol has some advantages such as the availability of starting materials, good yields, facile separation of products, the use of ethanol as an environmentally benign solvent and easy formation of three new bonds in one operation.

Introduction

The indole moiety is the most well-known heterocycle and a common and important feature of a variety of natural products and medicinal agents. Furthermore, it has been reported that the addition of the indole 3-carbon atom in the formation of spiroindoline derivatives highly enhances biological activity.

Spirooxindoles are a key structural element in a wide range of natural products with biological activities. They have attracted significant attention due to their useful pharmacological properties and biological activities including antimicrobial, anti-tumor, anti-tubercular, anti-inflammatory, anti-HIV, anti-fungal, the action as inhibitors of the human NK-1 receptor, anti-cancer, antibiotic, and anti-malarial.

Spirocyclic oxindoles containing a six-membered moiety, especially a six-membered piperidine structure at the C-3 position, have a wide spectrum of biological activities; examples include the non-peptidyl growth hormone secretagogue MK-0677 (ref. 14) and potent non-peptide MDM2 inhibitors, which may have utility as anticancer agents (Fig. 1).

During the last years, there has been considerable interest in the synthesis of spirooxindoles fused in the 3-position from three-membered to seven-membered spiro-rings and other fused heterocyclic compounds, which have multi-ring structures similar to spirooxindole dihydropyridines and spirooxindolepyrans.

Fig. 1 Bioactive and medicinally important compounds containing a spiropyridineoxindole skeleton.
a catalytic amount of NaCl by using ethylcyanoacetate and heterocyclic ketene aminals.\(^\text{28}\) In 2014, another reaction was reported using benzyloctonitrile and 2-(nitromethylene)imidazolone in ethanol and trimethylamine, which led to the corresponding product B.\(^\text{28}\)

In 2013, a method was developed using a mixture of ethyl trifluoroacetate, HKA and different isatins in the presence of piperidine in ethanol to give product C.\(^\text{24}\) In 2019, the four-component reaction of various amines and nitroketene dithioacetal with isatin and barbituric acid derivatives in water afforded spiroxindole D.\(^\text{21}\)

As a part of our program on the study of developing new multi-component reactions for the synthesis of heterocyclic compounds, we report the efficient synthesis of novel spiroimidazopyridineoxindole, spiropyrlyridopyrimidineoxindole and spiropyridodiazepineoxindole structures via a one-pot, four-component reaction of nitro ketene aminals derived from the addition of various 1,6-diamines to 1,1-bis(methylthio)-2-nitroethylene, isatin and its derivatives and Meldrum’s acid in the presence of p-TSA. To the best of our knowledge, these structures have not been synthesized so far and there are no reports on the preparation of spiroxindoles from Meldrum’s acid.

### Results and discussion

We prepared the spiropyridineoxindole derivative 5 via one-pot four-component condensation of diamine 1, 1,1-bis(methylthio)-2-nitroethylene 2, isatin 3 and Meldrum’s acid 4 in the presence of p-TSA catalyst in ethanol under reflux conditions (Scheme 1). The reaction was completed after 0.15–6 h to afford the corresponding heterocyclic systems 5a–j in moderate to good yields (69–87%).

For our initial investigation, the reaction of diamine 1a (1 mmol), dithioacetal 2 (1 mmol), isatin 3a (1 mmol) and Meldrum’s acid 4 (20% mmol) was considered as the model reaction. The effects of various catalysts, solvents and temperatures were monitored (Table 1). These results indicated that the best reaction conditions for the synthesis of spiroxindole 5a were obtained in ethanol as the solvent and by using p-TSA as the catalyst at reflux conditions. This procedure provided the highest yield of 87% and the shortest reaction time (Table 1, entry 7).

We explored the scope of this reaction by varying the structures of diamine 1a–d and isatin 3a–c components. The reaction proceeded to afford a series of spiropyridineoxindole derivatives 5a–j in 66–87% yields. The results are summarized in Table 2. This reaction was performed with other derivatives of isatin (N-benzyl and N-butyl isatin) under the same conditions but did not result in the product. Additionally, the reaction of N-ethyl isatin with 1,2-diaminopropane and 1,3-diaminopropane did not produce a product. Also, when 1,2-diaminocyclohexane was used for the synthesis of ketene aminal, no reaction occurred. We also tried using 1,2-diaminophenyl and aromatic amines in the reaction conditions. All the reactions were very slow and did not result in the desired products. The structures of compounds 5a–j were deduced from their mass, IR, 1H NMR, and 13C NMR spectroscopic data (ESI†).

The 1H and 13C NMR spectra of the crude products clearly indicate the formation of the suggested products 5a–j. As a representative case, the key signals of the 1H and 13C NMR chemical shifts for 8-nitro-2,3-dihydro-1H-spiroimidazo[1,2-a]pyridine-7,3′-indoline-2′,5(6H)-dione 5a are shown in the ESI.†

The 1H NMR spectrum of 5a shows the two NH groups (δ 9.57, 10.55 ppm) that are exchangeable with D2O. The two protons of methylene appear at δ 2.36 and 3.04 ppm as two doublets. Four protons of the aromatic ring can be observed at δ 6.81–7.20 ppm as four doublets. The 1H-decoupled 13C NMR spectrum of 5a indicates 14 distinct resonances in accordance with the desired structure. The characteristic signal of the carbon of the CH2 group is seen at δ 41.8 ppm. The carbon of the spiro center appears at δ 49.5 ppm. The two signals at δ 105.6 and 153.6 ppm are related to C=NO2 and C=C–NH, respectively. The two carbonyl groups appear at δ 165.6 and 177.6 ppm.

The mass spectrum of 5a displays a molecular-ion peak at m/z 300, which is in agreement with the proposed structure. The IR spectrum of 5a shows broad absorption bands due to NH at 3327 cm\(^{-1}\), stretching vibrations of the CH2 groups at 2920 cm\(^{-1}\), strong absorption bands of carbonyl groups at 1725 cm\(^{-1}\) and 1683 cm\(^{-1}\) and absorption bands at 1480 cm\(^{-1}\) and 1369 cm\(^{-1}\) related to NO2.

A plausible mechanism for the formation of spiropyridineoxindole 5 is depicted in Scheme 2. On the basis of the well-established chemistry of 1,1-bis(methylthio)-2-nitroethylene, initially, the addition of diamine 1 to 1,1-bis(methylthio)-2-nitroethylene 2 leads to the formation of ketene aminal 6. The second step involves the condensation of isatin 3 with Meldrum’s acid 4 in the presence of p-
et EtOH NEt₃ 18 0 7 5
tautomerization, followed by intramolecular cyclization
nucleophilic addition of

Thus, one equivalent of CO₂ and acetone are removed from
EtOH in a 50 mL
bis(methylthio)-2-nitroethylene (0.165 g, 1 mmol) and 10 mL
A mixture of ethylene diamine (66 mL, 1 mmol), 1,1-

Experimental
Materials
Meldrum’s acid, 1,1-bis(methylthio)-2-nitro ethylene, diamines,
various isatin derivatives, \( p \)-toluenesulfonic acid and solvents
were purchased from Sigma-Aldrich and used as received
without further purification. Melting points (mp) were determined
with an electrothermal 9100 apparatus. Infrared (IR)
spectra were recorded on a Bruker Tensor 27 spectrometer.
Nuclear magnetic resonance (NMR) spectra were obtained on
a Bruker DRX-300 Avance instrument (300 MHz for \( ^1 \text{H} \) and
75.4 MHz for \( ^13 \text{C} \)) with CDCl₃ and DMSO as solvents. Chemical shifts
were expressed in parts per million (ppm) relative to internal
TMS, and the coupling constant (\( J \)) was reported in hertz (Hz).
All of the compounds were analyzed for mass data using Agilent
5975C VL MSD with a Triple-Axis Detector operating at an
ionization potential of 70 eV.

General procedure for the synthesis of 8-nitro-2,3-dihydro-1H-spiro[imidazo[1,2-a]pyridine-7,3′-indoline]-2′,5′(6H)-dione (5a)
A mixture of ethylene diamine (66 mL, 1 mmol), 1,1-
bis(methylthio)-2-nitroethylene (0.165 g, 1 mmol) and 10 mL
EtOH in a 50 mL flask was refluxed for 6 h. After completion
of the reaction (monitored by TLC, ethyl acetate–n-hexane, 1 : 1),
isatin (0.147 g, 1 mmol), Meldrum’s acid (0.144 g, 1 mmol) and
\( p \)-toluenesulfonic acid (0.03 g, 0.2 mmol) were added to the
reaction mixture, and it was stirred under reflux for 0.15 h. The
progress of the reaction was monitored by TLC using ethyl
acetate–n-hexane (1 : 1) as an eluent. After reaction completion,
the precipitated product was collected by filtration and washed
with EtOH to give the pure product 5a in 87% yield.

Conclusion

We designed a novel and convenient procedure for the synthesis of three new classes of spiropyridineoxindoles with fused heterocyclic compounds (imidazole, pyrimidine and diazepine) in good yields via a four-component reaction among 1,1-bis(methylthio)-2-nitroethylene, various aliphatic diamines, Meldrum’s acid and isatin derivatives using a catalytic amount of p-TSA. The present process has several important features including mild and facile reaction conditions, easy accessibility of reactants, a simple workup procedure, the use of ethanol as a solvent, short reaction times, and good-to-high yields. These
structures having both indole and fused-pyridine moieties, which are some of the most typical privileged scaffolds, are completely new and there is no other report on their synthesis.
