(Dated: February 5, 2008)

A novel approximation scheme is proposed to describe the dynamics of the spin-boson problem. Being nonperturbative in the coupling strength nor in the tunneling frequency, it gives reliable results over a wide range of temperatures and coupling strength to the thermal environment for a large class of bath spectral densities. We use a path-integral approach and start from the exact solution for the two-level system population difference in the form of a generalized master equation (GME). Then, we approximate inter-blip and blip-sojourns interactions up to linear order, while retaining all intra-blip correlations to find the kernels entering the GME in analytical form. Our approximation scheme, which we call Weakly-Interacting Blip Approximation (WIBA), fully agrees with conventional perturbative approximations in the tunneling matrix element (Non-Interacting Blip Approximation) or in the system-bath coupling strength.

I. INTRODUCTION

Many physical and chemical two-level systems (TLSs) suffer the influence of external environments which cause decoherence effects1,2,3. Electron and proton transfer reaction in condensed phases,4,5 tunneling phenomena in condensed matter physics,6,7, or two-level atoms in an optical cavity8,9 are some very well known situations susceptible to lack of coherence. Dissipation processes are to be understood first, in order to provide, if required, further decoherence control schemes. An important footstep to allow experimental investigation of decoherence mechanisms was the realization of micrometer-sized objects like the radio-frequency superconducting quantum interference device (rf-SQUID)10. Recently, due to their scalability and to the ease to experimentally control their parameters, other superconducting devices as the flux-qubit11 or the Cooper-pair box10,11 have become attractive systems to explore quantum coherence on a fundamental basis and as possible basic unit (quantum-bit or qubit), for future quantum computers12.

The spin-boson model, where the TLS is bilinearly coupled to a bath of harmonic oscillators, is commonly used to quantitatively describe some aspects of the dissipative dynamics of the above mentioned systems. In the spin-boson problem, it is common to evaluate the dynamics of the expectation value of the pseudo-spin operator \( \langle \sigma_z(t) \rangle \) \( \equiv P(t) \), as this is the quantity of interest in the experiments.

To date, the spin-boson model has been mostly described within two main approximation schemes, each describing different regimes of temperature and coupling strength to the thermal bath. One main road of approximation is based on an expansion to leading order in the tunneling frequency \( \Delta \) (see Eq. (2) below), yielding the so-called noninteracting-blip approximation (NIBA)1,2,3. Equations of motion for the dynamical quantity \( P(t) \) equivalent to the NIBA were also obtained using projection operator techniques4,5,6,7,8. The NIBA equations are easily solved numerically and yield analytical solutions in special cases9,10,11. However, for a biased TLS they can be only used in the regime of high temperatures and/or strong friction. An improvement to the NIBA has been performed for a super-Ohmic bath, in the regime of strong coupling12. A more refined approach, which yields nonconvolutive dynamical equations, is the so-called interacting-blip chain approximation (IBCA)13,14,15.

In the range of weak TLS-bath coupling and low temperature, however, the above mentioned schemes fail to properly describe the dynamics of a biased TLS, e.g. a symmetry breaking at zero temperature even for vanishing asymmetries is predicted. In this regime, path-integral methods16,17,18 and as perturbation theories19,20,21 are used. The lowest order perturbation theory and the path-integral approach have been shown to yield the same dynamics for weak Ohmic damping22.

To date, only numerical techniques23,24,25,26,27,28,29,30,31,32 can provide a description of the TLS dynamics, being capable to smoothly match between the high and the weak-coupling regimes. However, ab-initio calculations can become costly if the regime of low temperatures or the long time dynamics are investigated.

In this work we propose a novel approximation scheme, which we call weakly-interacting blip approximation (WIBA), capable to bridge between the weak-coupling and strong-coupling theories. It is based on the observation that bath-induced correlations among “blips” and between “blips” and “sojourns” are intrinsically weak. Thus, in the WIBA, those correlations are included up to first order only. As in the NIBA, the time evolution of the population difference \( P(t) \) is given by the general master equation (GME) \( (t \geq 0) \)

\[
\dot{P}(t) = -\int_0^t dt' [K^a(t-t') - W(t-t') + K^a(t-t')P(t')] ,
\]

(1)
where the irreducible WIBA kernels $K^s$ and $K^a$ are, respectively, symmetric and antisymmetric with respect to an external bias $\varepsilon$. As discussed below, such kernels are neither perturbative in the tunneling matrix $\Delta$ nor in the TLS-bath coupling, see Eqs. (46), (47) and (48).

Since the inter-blip and blip-sojourn correlations become negligible at high temperatures or large system-bath coupling, the WIBA well matches the NIBA predictions in this regime. On the other hand, at low temperatures and couplings such correlations, neglected in the NIBA, become essential to properly describe the dynamics. In this limit, WIBA perfectly agrees with the predictions of the weak-coupling theories. Finally, in the intermediate coupling and temperature regime where the perturbative approaches fail, the WIBA yields a good agreement with predictions of ab-initio calculations.

The paper is organized as follows: In Sec. II we introduce the spin-boson model. Then, in Sec. III the Feynman real-time path-integral formalism is shortly reviewed, as it constitutes the starting point for the approximation schemes discussed in Secs. IV and V. Specifically, we introduce the so-called Feynman-Vernon influence functional and discuss an exact series expression for the expectation value of the system “coordinate” $P(t)$. Since the exact expression is nontrivial, the following Sections are dedicated to some approximation schemes. In Sec. IV an extended version of the familiar non-interacting blip approximation (extended-NIBA) is presented. There we derive a prescription to calculate the kernels entering an equation of the form (1). Sec. V finally contains the major findings of our work. There we introduce the WIBA, which is able to bridge between the weak and strong coupling regimes within the same theory. The WIBA kernels entering (1) are found in analytical form. A comparison with predictions of ab-initio calculations shows that the WIBA covers a wide spectrum of parameters and constitutes an interpolation between the NIBA and weak-coupling approximation schemes.

II. THE SPIN-BOSON MODEL

In this Section, the spin-boson model is shortly reviewed, and the dynamical variables of interest are defined. To start, we consider the pseudo-spin Hamiltonian in the "localized basis" $\{|L\rangle, |R\rangle\}$,

$$\hat{H}_0 = \frac{\hbar}{2} [\varepsilon \hat{\sigma}_z - \Delta \hat{\sigma}_x],$$

with $\hat{\sigma}_z$ and $\hat{\sigma}_x$ the Pauli matrices and $\hbar\Delta$ the energy separation of the two levels at zero bias ($\varepsilon = 0$) which accounts for the tunneling dynamics. Thus, we can interpret $\hat{\sigma}_z$ as a “position” operator such that $\langle L | \sigma_z | L \rangle = -1$ and $\langle R | \sigma_z | R \rangle = +1$.

We choose to model the environment as an ensemble of harmonic oscillators, which linearly couple to the system “position coordinate” $\sigma_z$, ending up with a bath Hamiltonian $\hat{H}_B$ of the form (including also the interaction between bath and system)

$$\hat{H}_B = \sum_{j=1}^{N} \left[ \frac{P_j^2}{m_j} + m_j \omega_j^2 x_j^2 \right] - \sum_{j=1}^{N} c_j \sigma_z x_j.$$  \hspace{1cm} (3)

The whole system is thus described by the well known spin-boson Hamiltonian $\hat{H} = \hat{H}_0 + \hat{H}_B$. In the case of a thermal equilibrium bath, its influence on the system is fully characterized by the spectral density

$$G(\omega) = \frac{\pi}{2} \sum_{j=1}^{N} \frac{c_j^2}{m_j \omega_j} \delta(\omega - \omega_j),$$

which reduces to a continuous spectral density once the number $N$ of harmonic oscillators approaches infinity. Throughout this work, we choose spectral densities with power-law behavior at low frequencies, i.e. ($s > 0$)

$$G(\omega) = 2\delta(\omega) - s \omega^{s-1} \omega^s e^{-|\omega|/\omega_c},$$

with $\delta(\omega)$ being a dimensionless coupling parameter, $\omega_c$ a characteristic phonon frequency, and $\omega_c$ the bath cutoff frequency which is taken to be the largest frequency in the model. Thus, this class encompasses the commonly considered Ohmic spectrum with exponential cutoff $G(\omega) = 2\omega e^{-|\omega|/\omega_c}$, with $\alpha = \delta_1$ being the so called Kondo parameter of the TLS.

In order to describe the system’s dynamics, we focus on the time evolution of the reduced density matrix (RDM) $\rho(t) = \text{tr}_B \mathbf{W}(t)$, which we obtain after tracing out all bath degrees of freedom from the total density matrix $\mathbf{W}(t)$. We choose a factorized initial condition, namely at time $t = 0$ the full density operator $\mathbf{W}(0)$ is expressed as a product of the initial system density operator $\rho^{(S)}(0)$ and the canonical bath density operator at temperature $T$. The initial preparation requires some attention. One could distinguish two different preparations, according to the time when the coupling between system and bath is switched on, which we assume to happen at a time $t_0 \leq 0$. In the first one, which we refer as “class A”, the bath is in canonical equilibrium and the system is being prepared at time $t_0 = 0$ in a certain state, e.g. corresponding to $\sigma_z = +1$. Then, the system evolves out of the state before the environment has relaxed to the shifted equilibrium distribution. This initial preparation is the typical situation in electron transfer reactions when a specific electronic donor is suddenly prepared by photoinjection. The other situation, “class B”, is when the system has been held for a long time in a certain state, e.g. $\sigma_z = +1$, so that the bath had time enough to thermalize with the system. It corresponds to choose $t_0 \to -\infty$. Then, at time $t = 0$, the constraint is released and the system evolves with the spin-boson Hamiltonian. This initial preparation is performed, e.g. in rf-SQUID devices by a suitable choice of an external magnetic field. We shall refer ourselves to such initial preparation throughout the work.
The diagonal elements of the RDM are called population, whereas the off-diagonal terms coherences. In particular, we denote with
\[ P_R(t) = \rho_{\sigma_1=1,\sigma'_1=1}(t) \equiv \rho_{RR}(t) \]  
(6)
the probability of finding the system in the right state at time \( t \) if it was prepared in the right state at time \( t = 0 \) as well (with \( P_L \) one denotes the analogous quantity for the left well).

In the spin-boson problem, it is common to evaluate the dynamics of the expectation value of the pseudo-spin operator \( \langle \sigma_z(t) \rangle = \rho_{RR}(t) - \rho_{LL}(t) \equiv P(t) \), namely the difference of populations in the localized basis. This quantity is also the quantity of interest of many experiments. Similar considerations as discussed in this work for \( P(t) \) can be done for the off-diagonal elements of the density matrix.

\section{III. REAL-TIME PATH-INTEGRAL APPROACH TO THE DYNAMICS}

In this Section we recall the main steps yielding an exact series expression for \( P(t) \), obtained within the path-integral approach.

\subsection{A. Influence functional and bath correlation function}

As we already anticipated, we assume a factorized initial condition at time \( t = 0 \). For such initial condition, the exact formal solution for the RDM can be expressed in terms of a real time double path integral over piecewise constant forward \( \sigma(\tau) \) and backward \( \sigma'(\tau) \) spin paths with values \( \pm 1 \). The effects of the environment are in an influence functional inducing non-local in time correlations between different path segments. Upon introducing the linear combinations \( \eta(\tau) = [\sigma(\tau) + \sigma'(\tau)]/2 \) and \( \xi(\tau) = [\sigma(\tau) - \sigma'(\tau)]/2 \), the population difference reads
\[ P(t) = \int \mathcal{D}\xi \mathcal{D}\eta A[\xi,\eta] \exp \{ \Phi[\xi,\eta] \} \]  
(7)
where \( A \) is the path weight in the absence of the bath coupling. A generic double path can now be visualized as a single path over the four-states of the reduced density matrix, characterized by \( (\eta(\tau) = \pm 1, \xi(\tau) = 0) \) and \( (\eta(\tau) = 0, \xi(\tau) = \pm 1) \). The time intervals spent in a diagonal \( (\xi(\tau) = 0) \) and off-diagonal \( (\eta(\tau) = 0) \) state are dubbed “sojourns” and “blips”, respectively (see Fig. 1). Due to the initial condition, the path sum runs over all paths with boundary conditions \( \xi(0) = \xi(t) = 0 \) and \( \eta(0) = 1, \eta(t) = \pm 1 \). Environmental effects are included in the influence functional
\[ \Phi[\xi,\eta] \equiv \int_0^t dt_2 \int_0^{t_2} dt_1 \xi(t_2) \left[ S_{2,1} \dot{\xi}(t_1) + iR_{2,1} \eta(t_1) \right] \]  
(8)
with the bath correlation function \( Q = S + iR \) being
\[ Q(t) = \int_0^\infty d\omega G(\omega) \frac{\coth (\frac{\hbar \omega}{2k_B T})}{\omega^2} [1 - \cos \omega t] + i \sin \omega t \]  
(9)
and \( Q_{j,k} := Q(t_j - t_k) \). For the class of spectral densities considered in Eq. (4), the functions \( S \) and \( R \) read
\[ S(t) = 2\delta \Gamma(s-1) \left( \frac{\omega}{\omega_{ph}} \right)^{s-1} \left[ 1 - (1 + (\omega \tau)^2)^{\frac{s-1}{2}} \right] \]  
(10)
\[ \times \cos [(s-1) \arctan (\omega \tau)] + (\hbar \beta \omega_{ph})^{1-s} \left[ 2 (s-1,1+\kappa) \right. \]  
\[ - \zeta \left( s-1,1+\kappa + i \frac{t}{\hbar \beta} \right) + \left. \zeta \left( s-1,1+\kappa - i \frac{t}{\hbar \beta} \right) \right] \]  
(11)
and
\[ R(t) = 2\delta \Gamma(s-1) \left( \frac{\omega}{\omega_{ph}} \right)^{s-1} \]  
(12)
\[ \times \left[ 1 + (\omega \tau)^2 \right]^{\frac{s-1}{2}} \sin [(s-1) \arctan (\omega \tau)], \]
where \( \Gamma(z) \) is the Euler’s gamma function and \( \zeta(q,z) \) is the Riemann’s generalized zeta function. Moreover, \( \kappa = 1/\hbar \beta \omega_c \) becomes important as the ratio \( k_B T/\hbar \omega_c \) becomes large.

For a generic path with \( 2n \) transitions at times \( t_j, j = 1,2,...,2n \), one finds \( \xi(\tau) = \sum_{j=1}^{2n} \xi_j \delta(\tau - t_j) \) and \( \eta(\tau) = \sum_{j=0}^{2n} \eta_j \delta(\tau - t_j) \). Here is \( \eta_0 = 1 \) due to the initial preparation and \( \xi_j = \pm 1, \eta_j = \pm 1 \) for \( j > 0 \). Because \( \xi_{2j} = -\xi_{2j-1} \), the influence function in (8) becomes \( \Phi^{(n)} = \Phi^{(n)}_{\text{intra, bps}} + \Phi^{(n)}_{\text{inter}} \) (Fig. 2). The function \( \Phi^{(n)}_{\text{intra, bps}} \) describes intra-blip and blip-preceding sojourn correlations, and reads
\[ \Phi^{(n)}_{\text{intra, bps}} = - \sum_{j=1}^{n} \left[ S_{2j-2j-1} - i \xi_j \eta_{j-1} X_{j,j-1} \right] \]  
(12)
\[ = \Phi^{(n)}_{\text{intra}} + \Phi^{(n)}_{\text{bps}}, \]
FIG. 2: Bath-induced non-local in time correlations among tunneling transitions. The interactions \( S_{j,j-1} \), \( R_{j,j-1} \), and \( Y_{j,j-1} \) (intra-dipole and blip-preceeding-sojourn interactions) which appear in the influence phase \( \Phi_{\text{intra,bps}} \), cf. Eq. (12), are symbolized by the wiggled lines (blue and magenta online, respectively). The double-dashed lines denote the inter-dipole interactions \( \Lambda_{j,k} \), while the bold-dotted lines are the remaining blip-sojourn interactions \( X_{j,k} \) contained in the influence phase \( \Phi_{\text{inter}} \), cf. Eq. (13).

\[
\Phi^{(n)}_{\text{intra}} = -\sum_{j=1}^{n} \left[ S_{2j,2j-1} - i\xi_{j}\eta_{j-1}R_{2j,2j-1} \right], \quad (13)
\]

\[
\Phi^{(n)}_{\text{bps}} = i \sum_{j=1}^{n} \xi_{j}\eta_{j-1}Y_{j,j-1}, \quad (14)
\]

where we split \( X_{j,j-1} = R_{2j,2j-1} + Y_{j,j-1} \), with

\[
Y_{j,j-1} = R_{2j-1,2j-2} - R_{2j,2j-2}. \quad (15)
\]

Moreover, the functional \( \Phi^{(n)}_{\text{inter}} \) accounts for inter-blip and blip-sojourn interactions:

\[
\Phi^{(n)}_{\text{inter}} = -\sum_{j=2}^{n} \sum_{k=1}^{j-1} \xi_{j}\xi_{k}\Lambda_{j,k} + i \sum_{j=2}^{n} \sum_{k=0}^{j-2} \xi_{j}\eta_{k}X_{j,k}. \quad (16)
\]

The function \( \Lambda_{j,k} \) contains the blip-blip interactions between the flip pairs \( \{j, k\} \), while the blip-sojourn interaction \( X_{j,k} \) yields a phase factor. To be definite, for \( k > 0 \),

\[
\Lambda_{j,k} = S_{2j,2k-1} + S_{2j-1,2k} - S_{2j,2k} - S_{2j-1,2k-1}, \quad (17a)
\]

\[
X_{j,k} = R_{2j,2k+1} + R_{2j-1,2k} - R_{2j,2k} - R_{2j-1,2k+1}. \quad (17b)
\]

The correlations \( X_{j,0} \) depend on the initial preparation, being of class A or B.

**B. Exact series expression for \( P(t) \)**

The summation over the path histories reduces to an expansion in the number of tunneling transitions yielding a formally exact series expression for the population difference \( P(t) \). It reads (here we identify \( \eta_{2n} \) with \( \eta_{f} \))

\[
P(t) = \sum_{\eta_{f}=\pm 1} \eta_{f}J(\eta_{f}, t; \eta_0 = 1, 0), \quad (18)
\]

with the conditional propagating function being

\[
J(\eta_{f}, t; \eta_0 = 1, 0) = \delta_{\eta_{f},\eta_0} + \sum_{n=1}^{\infty} \int_{0}^{t} \mathcal{D}\{t_{j}\} \left( -\frac{\Delta^2}{2} \right)^{n} \times \sum_{\{\xi_{j}=\pm 1\}} B_{n} \sum_{\{\eta_{j}=\pm 1\}'} \exp\{\Phi^{(n)}_{\{\eta_{j}=\pm 1\}'}\}, \quad (19)
\]

with \( B_{n} \equiv \exp\{-i\pi \sum_{j=1}^{n} \xi_{j}\tau_{j}\} \), and where we defined the blip length as \( \tau_{j} \equiv t_{2j} - t_{2j-1} \). In (19), \( n \) counts the number of blips and the prime in \( \{\eta_{j}=\pm 1\}' \) means that the sum does not run over the initial and final sojourns, since they are fixed. Moreover,

\[
\int_{0}^{t} \mathcal{D}\{t_{j}\} \equiv \int_{0}^{t} dt_{2n} \int_{0}^{t_{2n}} dt_{2n-1} \cdots \int_{0}^{t_{2}} dt_{1}. \quad (20)
\]

Performing the summation over the intermediate sojourns, one gets for the population difference \( P(t) \):

\[
P(t) = 1 + \sum_{n=1}^{\infty} \int_{0}^{t} \mathcal{D}\{t_{j}\} \left( -\frac{\Delta^2}{2} \right)^{n} \times \sum_{\{\xi_{j}=\pm 1\}} \left( F^{(+)}_{n} B^{(s)}_{n} + F^{(-)}_{n} B^{(a)}_{n} \right), \quad (21)
\]

where \( F^{(+)}_{n} \equiv \cos \left( \varepsilon \sum_{j=1}^{n} \xi_{j}\tau_{j} \right) \), \( B^{(a)}_{n} \equiv \sin \left( \varepsilon \sum_{j=1}^{n} \xi_{j}\tau_{j} \right) \) and

\[
F^{(+)}_{n} \equiv G_{n} \prod_{k=0}^{n-1} \cos \left( \phi_{k,n} \right), \quad (22a)
\]

\[
F^{(-)}_{n} \equiv G_{n} \sin \left( \phi_{0,n} \right) \prod_{k=1}^{n-1} \cos \left( \phi_{k,n} \right), \quad (22b)
\]

with \( \phi_{k,n} \equiv \sum_{j=k+1}^{n} \xi_{j}X_{j,k} \) and

\[
G_{n} \equiv \exp \left\{ \text{Re} \left[ \Phi^{(n)}_{\{\eta_{j}=\pm 1\}'} \right] \right\} \equiv \exp \left\{ -\sum_{j=1}^{n} S_{2j,2j-1} - \sum_{j=2}^{n-1} \xi_{j}\xi_{k}\Lambda_{j,k} \right\}. \quad (23)
\]

The expression (21) is still practically untractable. Thus, it is necessary to perform some approximations to describe the TLS dynamics. Two novel approximation schemes are discussed in the coming Sections IV and V.

**IV. THE EXTENDED NON-INTERACTING BLIP APPROXIMATION**

In this Section we discuss an improvement to the familiar non-interacting blip approximation (NIBA), which better treats the blip-preceeding sojourns interactions. We call our more refined approximation scheme
tended localization of the TLS (\(\Lambda_{j,k}\) approximations the inter-blip and blip-sojourns correlations to the initial preparation (here we choose the preparation of retained. The first sojourn is treated differently, according to the influence phase \(\Phi_{\text{init}}\) (magenta online), which contributes to the influence phase \(\Phi_{\text{init}}\) (see Eq. (12)) and is being neglected in the NIBA, The first sojourn is treated differently, according to the initial preparation (here we choose the preparation of “class B”).

“extended-NIBA” (see Fig. 3). As we shall see, as the NIBA, the extended-NIBA enables to recast the series expression for \(P(t)\) into a generalized master equation (GME) of the form (1) with kernels of second order in the level splitting \(\Delta\).

The advantage of the NIBA relies on its extreme simplicity and on the fact that it is non-perturbative in the coupling to the bath. Hence, the non-interacting blip approximation is a popular approximation scheme. Nevertheless, it has some intrinsic weaknesses, especially in the asymmetric case (i.e. \(\epsilon \neq 0\)) for low temperature and weak coupling. For example, NIBA predicts the unphysical asymptotic limit \(\sigma_{\text{NIBA}}^{\infty,0} = -\tanh(\frac{\hbar \omega}{2T})\), implying a localization of the TLS (\(\sigma_{\text{NIBA}}^{\infty,0} = -1\)) at zero temperature even for vanishing asymmetries.

The limits of validity of the theory are still dim, this approximation holding whenever the average time spent in a diagonal state (sojourn) \(\langle s \rangle\) is very large compared to the average time spent in an off-diagonal state (blip) \(\langle \tau \rangle\). Within the NIBA, the full inter-blip correlations \(\Lambda_{j,k}\) and the blip-sojourn interactions \(X_{j,k}\) with \(j \neq k + 1\) are neglected (\(\Phi_{\text{inter}}^{(n)} \approx 0\). The blip-preceding-sojourn interactions \(Y_{j,j-1}\) in Eq. (13) are neglected as well (see Fig. 3b). Hence, \(G_{\text{NIBA}} \approx \exp \left\{ \text{Re} \left[ \Phi_{\text{intra}}^{(n)} \right] \right\} \). The explicit form of the NIBA kernel is given in Appendix A.

In the following Sec. V we shall introduce a novel approximation scheme, the weakly-interacting blip approximation (WIBA), capable to overcome these drawbacks. Before doing this, however, we need to introduce the extended-NIBA where, as in NIBA, \(\Phi_{\text{inter}}^{(n)} \approx 0\), but the blip-preceding-sojourn correlations \(Y_{j,j-1}\) are retained, despite in approximate form.

### A. Series expression within the extended-NIBA

After performing the sum over the blip indices \(\xi_{j} = \pm 1\) in Eq. (24), the extended-NIBA prescription \(\Phi_{\text{inter}}^{(n)} = 0\) yields for the probability difference \(P_{\text{EN}}(t)\):

\[
P_{\text{EN}}(t) = 1 + \sum_{n=1}^{\infty} (-1)^{n} \int_{0}^{t} D\{ t_{j} \} \left[ g(\tau_{j}, s_{0}) \right]^{n} h(\tau_{j}, s_{j-1}) ,
\]

where \(\tau_{j} = t_{2j} - t_{2j-1}\) and \(s_{j} := t_{2j+1} - t_{2j}\) denotes the sojourn length. The extended-NIBA kernels are defined as

\[
g(\tau_{j}, s_{j-1}) = \Delta^{2} e^{-S(\tau_{j})} \cos(\epsilon \tau_{j}) \cos[X_{j,j-1}] ,
\]

\[
h(\tau_{j}, s_{j-1}) = \Delta^{2} e^{-S(\tau_{j})} \sin(\epsilon \tau_{j}) \sin[X_{j,j-1}] .
\]

Remember that \(X_{j,j-1} = R(\tau_{j}) - R(\tau_{j} + s_{j-1}) + R(s_{j-1})\). The functions \(g(\tau_{j}, s_{0})\) and \(h(\tau_{j}, s_{0})\) explicitly depend on the length \(s_{0}\) of the initial sojourn, and assume a different form for preparation class A and B.

In the following, we choose a factorized initial condition at time \(t = 0\) with the particle being held at the site \(|R\rangle\) (\(\sigma_{z} = +1\)) from time \(t_{0} = -\infty \) till \(t = 0\) (class B), which amounts to consider \(s_{0} \to \infty\). Hence, Eq. (24) for \(j = 1\) reads

\[
g(\tau_{1}, s_{0} \to \infty) = \Delta^{2} e^{-S(\tau_{1})} \cos(\epsilon \tau_{1}) \cos[R(\tau_{1})] \equiv g_{N}(\tau_{1}) ,
\]

\[
h(\tau_{1}, s_{0} \to \infty) = \Delta^{2} e^{-S(\tau_{1})} \sin(\epsilon \tau_{1}) \sin[R(\tau_{1})] \equiv h_{N}(\tau_{1}) ,
\]

being independent of \(s_{0}\). Notice that \(g_{N}(\tau_{1})\) and \(h_{N}(\tau_{1})\) coincide with the symmetric and antisymmetric NIBA kernels, respectively (cf. Eq. (A1)).

Due to the convolutive structure of Eq. (24), it is easier to evaluate the probability difference upon Laplace transformation. By exchanging the integration order and performing some change of variables, one gets

\[
\tilde{P}_{\text{EN}}(\lambda) = \frac{1}{\lambda} + \sum_{n=1}^{\infty} (-1)^{n} \int_{0}^{\infty} D\{ t_{j} \} \left[ g(\tau_{j}, s_{0}) + h(\tau_{j}, s_{0}) \right]^{n} \int_{\tau_{j}}^{\infty} g(\tau_{j}, s_{j-1}) ,
\]

where \(\tilde{P}(\lambda) \equiv \int_{0}^{\infty} dt \exp[-\lambda t] P(t) = \mathcal{L}_{t}[P(t)]\) and

\[
\int_{0}^{\infty} D\{ t_{j} \} \left[ g(\tau_{j}, s_{j-1}) \right] = \int_{0}^{\infty} ds_{n} \int_{0}^{\infty} d\tau_{n} \int_{0}^{\infty} ds_{n-1} \times \ldots \int_{0}^{\infty} ds_{1} \int_{0}^{\infty} d\tau_{1} \int_{0}^{\infty} ds_{0} e^{-\lambda \tau_{j} + s_{j-1} + s_{0}}
\]

\[
= \int_{0}^{\infty} ds_{n} e^{-\lambda s_{n}} \times \int_{0}^{\infty} d\xi_{n} e^{-\lambda \xi_{n}} \int_{0}^{\infty} d\tau_{n} \ldots \int_{0}^{\infty} d\xi_{1} e^{-\lambda \xi_{1}} \int_{0}^{\infty} d\tau_{1} ,
\]
with $\xi_j \equiv \tau_j + s_{j-1}$ the length of each blip plus its preceding sojourn. Let us introduce the functions

$$F(\xi_j) \equiv \int_0^{\xi_j} dt_j g(\tau_j, \xi_j - \tau_j), \quad j > 1,$$

$$F_0(\xi_1) \equiv \int_0^{\xi_1} dt_1 g_S(\tau_1),$$

$$A_0(\xi_1) \equiv \int_0^{\xi_1} dt_1 h_N(\tau_1),$$

where the $1/\lambda$ comes from the free last sojourn $s_n$, or equivalently

$$\hat{P}_N(\lambda) = \frac{1}{\lambda} \sum_{n=1}^{\infty} \prod_{j=2}^{\infty} \left[ -\mathcal{L}_{\xi_j} F(\xi_j) \right] (\lambda) \times \left[ -\mathcal{L}_{\xi_1} \{F_0(\xi_1) + A_0(\xi_1)\} \right] (\lambda),$$

(31)

noticing that $X_{j,j-1} = R(\tau_j) - R(\xi_j) + R(\xi_j - \tau_j)$. Then $\hat{P}(\lambda)$ assumes the form

$$\hat{P}(\lambda) = \frac{1}{\lambda} \sum_{n=1}^{\infty} \left[ -\hat{F}(\lambda) \right]^{n-1} \left[ \hat{F}_0(\lambda) + \hat{A}_0(\lambda) \right]$$

$$= \frac{1}{\lambda} \left[ -\hat{F}(\lambda) + \hat{A}_0(\lambda) \right]$$

(32)

It is convenient to introduce the functions

$$K_{\lambda N}(\lambda) \equiv \lambda A_0(\lambda), \quad K_{\lambda N}(\lambda) \equiv \lambda \hat{F}(\lambda)$$

and

$$\hat{W}_{\lambda N}(\lambda) \equiv \lambda \left[ \hat{F}(\lambda) - \hat{F}_0(\lambda) \right].$$

Then Eq. (32) becomes

$$\hat{P}(\lambda) = \frac{1}{\lambda} \left[ K_{\lambda N}(\lambda) - \hat{W}_{\lambda N}(\lambda) \right] \lambda + K_{\lambda N}(\lambda).$$

(33)

B. Generalized master equation (GME) for the extended-NIBA model

Eq. (33) can be easily transformed back to the time domain. We find

$$\hat{P}_N(t) = -\int_0^t dt' [K_{\lambda N}(t - t') - W_{\lambda N}(t - t') + \hat{K}_{\lambda N}(t - t') P_N(t')]$$

(34)

with extended-NIBA kernels defined as

$$K_{\lambda N}(t) \equiv \frac{d}{dt} \hat{F}(t) \equiv \hat{F}(t),$$

$$K_{\lambda N}(t) \equiv \frac{d}{dt} \hat{A}_0(t) \equiv \hat{A}_0(t),$$

$$\hat{K}_{\lambda N}(t) \equiv \frac{d}{dt} \hat{F}_0(t) \equiv \hat{F}_0(t),$$

$$W_{\lambda N}(t) \equiv \hat{K}_{\lambda N}(t) - \hat{K}_{\lambda N}(t).$$

(35)

Although the time derivatives (35) can be straightforwardly calculated from Eqs. (30), the explicit dependence of the function $g(\tau_j, \xi_j - \tau_j)$ on $\xi_j$ still implies an integral form for the function $F(\xi_j)$. An approximate form of $\hat{F}(\xi_j)$ can be obtained if we observe that the average blip length $\langle \tau \rangle$ is suppressed by the intra-blip interaction $\exp[-S(\tau)]$ in the integrands of Eq. (30) and that the imaginary part of the bath correlation function $R(t)$, Eq. (11), slightly deviates from a constant. Hence, we approximate

$$-R(\xi_j) + R(\xi_j - \tau_j) \approx -\tau_j \tilde{R}(\xi_j) + O[\tau_j^2 \tilde{R}(\xi_j)].$$

(36)

Corrects proportional to the second derivative of $R(t)$ have been neglected. The functions $g(\tau_j, s_j)$ and $h(\tau_j, s_j)$ defined in Eq. (20) become $j > 1$

$$g(\tau_j, \xi_j - \tau_j) \approx \tilde{g}(\tau_j, \xi_j)$$

$$:= \Delta^2 e^{-S(\tau_j)} \cos(\varepsilon \tau_j) \cos[R(\tau_j) - \tau_j \tilde{R}(\xi_j)],$$

$$h(\tau_j, \xi_j - \tau_j) \approx \tilde{h}(\tau_j, \xi_j)$$

$$:= \Delta^2 e^{-S(\tau_j)} \sin(\varepsilon \tau_j) \sin[R(\tau_j) - \tau_j \tilde{R}(\xi_j)],$$

(37)

the corrections being of order $O[\tau_j^2 \tilde{R}(\xi_j)]$. In particular, we define $g_N(\xi_j)$ and $h_N(\xi_j)$ as

$$g_N(\xi_j) \equiv \tilde{g}(\xi_j, \xi_j) = \Delta^2 e^{-S(\xi_j)} \cos(\varepsilon \xi_j) \cos[R(\xi_j)],$$

$$h_N(\xi_j) \equiv \tilde{h}(\xi_j, \xi_j) = \Delta^2 e^{-S(\xi_j)} \sin(\varepsilon \xi_j) \sin[R(\xi_j)],$$

(38)

where $\tilde{R}(t) \equiv R(t) - t \tilde{R}(t)$. The extended-NIBA kernels, obtained as prescribed by Eqs. (35) and (36), then read

$$K_u^{\lambda N} (t) := g_N(t),$$

$$K_e^{\lambda N} (t) := h_N(t),$$

$$K_0^{\lambda N}(t) := \gamma \rho_N(t),$$

$$W_N(t) := g_N(t) - g_N(t).$$

(39)

The irreducible kernel $K_u^{\lambda N}(t)$ entering the extended-NIBA master equation (34) is shown in Fig. 4a. The irreducible NIBA kernel $K_u^N(t)$, Eq. (A11), is depicted in Fig. 4b. As discussed in App. A within the NIBA an analogous GME as in (34) is obtained where, due to the approximation $\Phi^{(n)}_{\lambda N} = 0$, is $W_N(t) = 0$.

The extended-NIBA kernels $K_u^{\lambda N}$ and $K_e^{\lambda N}$ differ from the conventional NIBA ones, $K_u^N$ and $K_e^N$, by the replacing of the imaginary part of the bath correlation function $R(t)$ with the “dressed” one $R(t) \equiv R(t) - t \tilde{R}(t)$ (see Fig. 4b). At small coupling strength, the NIBA is recovered.
since blip-preceeding-sojourn correlations become negligible. Despite its simplicity, however, the extended-NIBA already yields an improvement to the NIBA in the intermediate coupling regime (see Fig. 5).

FIG. 5: A comparison between the standard NIBA and the extended-NIBA for an Ohmic bath \((s = 1)\) is shown. The parameters are: \(T = 0.1, \alpha = 0.1, \varepsilon = 1\) (in units of the tunneling frequency \(\Delta\)). One can see that in the chosen intermediate parameter regime the extended-NIBA coincides with the conventional one at short times. However, it predicts a different asymptote from the NIBA one (see inset). Hence, at moderate damping and temperatures, the blip-preceeding-sojourn correlations retained in the extended-NIBA become important.

V. THE WEAKLY-INTERACTING BLIP APPROXIMATION (WIBA)

To bridge between the strong damping situation described by the NIBA and the extremely underdamped case we observe that, for spectral densities of the form \((s = 1)\), the blip-blip interaction terms \(\Lambda_{j,k}\) as well as the blip-sojourn terms \(X_{j,k}\) \((k \neq j - 1)\) are intrinsically small. Therefore, we propose a novel approximation scheme, which we call weakly-interacting blip approximation (WIBA). Within the WIBA, the full \(\Phi_{\text{intra,bps}}^{(n)}\) is retained as in the extended-NIBA and one expands the influence functional \(\exp \{ \Phi_{\text{inter}}^{(n)} \}\) up to linear order in the blip-blip and blip-preceeding sojourns interactions \(\Lambda_{j,k}\) and \(X_{j,k}\) (see Fig. 6). Hence,

\[
\exp \{ \Phi^{(n)} \} \approx \exp \{ \Phi_{\text{intra,bps}}^{(n)} \} \left( 1 + \Phi_{\text{inter}}^{(n)} \right). \tag{40}
\]

In other terms, all contributions which involve \(\phi_{k,n}\) (cf. Eq. (22)) must be expanded up to first order in \(X_{j,k}\), \(j > k + 2\), and \(G_n \approx \exp \{ \Re \left[ \Phi_{\text{intra,bps}}^{(n)} \right] \} \left( 1 + \Re \left[ \Phi_{\text{inter}}^{(n)} \right] \right)\) (cf. Eq. (24)). All terms of the order \(AX\) or higher are neglected. As usual, the first sojourn and blip must be treated differently from the others, according to the initial preparation.

The inter-blip and blip-sojourns correlations \(\Lambda_{j,k}\) and \(X_{j,k}\) are known to become essential to properly describe the dynamics of a biased TLS at low temperatures. Specifically, in Ref. 23 a systematic weak-coupling approximation (WCA) was developed where all bath-induced correlations were linearized: \(\exp \{ \Phi^{(n)} \} \approx 1 + \Phi^{(n)}\). It was shown in Ref. 27 that the WCA exactly matches results obtained within the lowest-order Born approximation for weak-coupling to an Ohmic bath.

Hence, the WIBA constitutes an improvement of the extended-NIBA model on one side and of the WCA on the other. At high temperatures, where the dipole-dipole interactions are negligible, the WIBA kernels reduce to the extended-NIBA ones. By expanding the WIBA kernels to first order in \(\delta_s\), the weak damping kernels in Refs. 22,23 are recovered.

In contrast to the extended-NIBA or the weak-coupling approximation, the WIBA has no small parameter in a strict sense, and it is based on the consideration that the correlations \(\Phi_{\text{inter}}^{(n)}\) are intrinsically weak over the whole parameter regime. As we show below, the WIBA indeed well describes the TLS dynamics over a wide parameter range.

A. Series expression within the WIBA

Let us again start from Eq. (21) and apply the WIBA prescription. After performing the sum over \( \xi_0 = \pm 1\) we then find

\[
P_{\text{WIBA}}(t) = 1 + \int_0^t dt_2 \int_0^{t_2} dt_1 \left[ \delta(t - t_1) - (g_1 + h_1) \right] + \sum_{n=2}^{\infty} (-1)^n \int_0^t \mathcal{D}[t_j] \left( g_1 + h_1 \right) \left( \prod_{j=2}^n g_j \right) + \sum_{l=2}^n \left( \prod_{j=l+1}^n g_j \right) \left[ -\tilde{h}_l \left( \prod_{j=2}^{l-1} g_j \right) (g_1 - \tilde{h}_1) \Lambda_{l,1} \right] + \tilde{h}_l \left( \prod_{j=2}^{l-1} g_j \right) (g_1 + h_1) X_{l,0} \right]
\]
\[ + \sum_{l=3}^{n} \sum_{k=2}^{l-1} \left( \prod_{j=l+1}^{n} g_j \right) \left[ \tilde{h}_l \left( \prod_{j=k+1}^{l-1} g_j \right) \tilde{h}_k \Lambda_{l,k} \right] \]
\[ + \tilde{h}_l \left( \prod_{j=k+1}^{l-1} g_j \right) h_k X_{l,k-1} \left( \prod_{j=2}^{l-1} g_j \right) \left( g_1 + h_1 \right) \right) \]
\[ = P_{\text{N}}(t) + P_{\text{inter}}(t), \tag{41} \]

where \( P_{\text{N}}(t) \) is the extended-NIBA expression \(^{(29)}\), while \( P_{\text{inter}}(t) \) contains the contributions coming from the linearized influence functional \( \exp \{ \Phi^{(n)}_{\text{inter}} \} \), cf. \(^{(40)}\). A graphical representation of the time-ordered sequences entering Eq. \((41)\) is shown in Fig. 6. In \((41)\), \( g_j \) and \( h_j \) are the functions already occurring in \((25)\):
\[ g_j \equiv g(\tau_j, s_{j-1}), \]
\[ h_j \equiv h(\tau_j, s_{j-1}). \tag{43} \]

The functions \( \bar{g}_j \) and \( \bar{h}_j \) are analogously defined as
\[ \bar{g}_j \equiv \Delta^2 e^{-S(\tau)} \cos(\varepsilon \tau) \sin[X_{t,j-1}], \]
\[ \bar{h}_j \equiv \Delta^2 e^{-S(\tau)} \sin(\varepsilon \tau) \cos[X_{t,j-1}]. \tag{44} \]

Notice that \( g_j \) and \( \bar{g}_j \) are symmetric in the bias, while \( h_j \) and \( \bar{h}_j \) are antisymmetric. Moreover,
\[ g_1 = g_0(\tau_1), \]
\[ h_1 = h_0(\tau_1), \tag{45} \]

\[ \text{cf. Eq. (27), and analogously for } \bar{g}_1 \text{ and } \bar{h}_1. \] 

To proceed, let us consider the function (for \( k > 1 \))
\[ \Sigma_{s}^{(l-k+1)}(t_{2l} - t_{2k-2}) = \int_{t_{2k-2}}^{t_{2l}} dt_{2l-1} \ldots \int_{t_{2k-2}}^{t_{2k}} dt_{2k-1} \]
\[ \times \tilde{h}_l \left( \prod_{j=k+1}^{l-1} g_j \right) \left[ h_k \Lambda_{l,k} + h_k X_{l,k-1} \right] \tag{47} \]

entering \((41)\), where \( 2(l - k + 1) \) denotes the number of tunneling transitions. Upon introducing the variables \( \xi \equiv t_{2l} - t_{2k-2} \) and \( \xi_j \equiv \tau_j + s_{j-1} \), Eq. \((47)\) assumes the form
\[ \Sigma_{s}^{(l-k+1)}(\xi) = \int_{0}^{\xi} d\xi_k \int_{0}^{\xi_k} d\xi_l \gamma_{\tilde{h}_l}(\xi_l) f(\xi - \xi_k - \xi_l) \]
\[ \times [\gamma_{h_k}(\xi_k) X_{t,l-1} + \gamma_{\bar{h}_k}(\xi_k) \Lambda_{l,k}] \tag{48} \]

where \( \gamma_{h_j/\bar{h}_j}(\xi_j) \) is an operator which acts on a generic function \( w(\tau_j) \) as (e.g. let us consider the operator \( \gamma_{h_j}(\xi_j) \))
\[ \gamma_{h_j}(\xi_j) w := \int_{0}^{\xi_j} d\tau_j \ h(\tau_j, \xi_j - \tau_j) w(\tau_j). \tag{49} \]

In \((48)\), the function \( f \) is given by the expression
\[ f(t_{2l-2} - t_{2k}) = \delta(t_{2l-2} - t_{2k}) \]
\[ + \int_{t_{2k}}^{t_{2l-2}} dt_{2l-3} \ldots \int_{t_{2k}}^{t_{2k+2}} dt_{2k+1} \left( \prod_{j=k+1}^{l-1} g_j \right) \tag{50} \]

Upon introducing \( s \equiv t_{2l-2} - t_{2k} \) and \( \xi_j \equiv \tau_j + s_{j-1} \) as in Eq. \((48)\), we find
\[ f(s) = \delta(s) \]
\[ + \int_{0}^{s} d\xi_{k+1} \int_{0}^{\xi_{k+1}} d\xi_k \left[ -g(\tau_{k+1}, \xi_{k+1} - \tau_{k+1}) \right] \]
\[ \times \ldots \int_{0}^{s - \sum_{j=k+1}^{l-3} \xi_j} \left[ -g(\tau_{l-2}, \xi_{l-2} - \tau_{l-2}) \right] \]
\[ \times \int_{0}^{s - \sum_{j=k+1}^{l-2} \xi_j} \left[ -g(\tau_{l-1}, s - \sum_{j=k+1}^{l-2} \xi_j - \tau_{l-1}) \right] \]
\[ = \delta(s) + p_{\text{N}}^{(l-k-1)}(s), \tag{51} \]

where the first derivative of the conditional probability \( p_{\text{N}}(s) \) has been introduced. It satisfies the master equation for the extended-NIBA with the symmetric kernel only:
\[ \dot{p}_{\text{N}}(t) = - \int_{0}^{t} dt' K_{\text{N}}(t - t') p_{\text{N}}(t'). \tag{52} \]

Analogously, we can treat the contributions to \( P_{\text{inter}} \) which depend on the initial preparation. Specifically, we introduce for the case \( k = 1 \) (here \( \xi \equiv t_{2l} - 0 \))
\[ \Sigma_{0,a}^{(l)}(\xi) \equiv \int_{0}^{\xi} d\xi_1 \int_{0}^{\xi_1} d\xi_2 \gamma_{\tilde{h}_1}(\xi_2) f(\xi - \xi_1 - \xi_2) \]
\[ \times [\gamma_{\bar{g}_1}(\xi_1) X_{t,0} - \gamma_{\bar{g}_1}(\xi_1) \Lambda_{0,1}] \tag{53} \]
\[ \Sigma_{0,a}^{(l)}(\xi) \equiv \int_{0}^{\xi} d\xi_1 \int_{0}^{\xi_1} d\xi_2 \gamma_{\tilde{h}_1}(\xi_2) f(\xi - \xi_1 - \xi_2) \]
\[ \times [\gamma_{h_1}(\xi_1) X_{t,0} + \gamma_{\bar{h}_1}(\xi_1) \Lambda_{0,1}] \tag{54} \]

where the operators \( \gamma_{\bar{g}_1/\bar{h}_1}(\xi_1) \) act analogously as in \((49)\), and \( f(s) = \delta(s) + p_{\text{N}}^{(l-2)}(s) \).

As discussed in the Sec. 4.4.3, we choose a factorized initial condition at time \( t = 0 \), which corresponds to set \( s_0 \to \infty \). This means that in Eqs. \((53)\) and \((54)\), \( X_{t,0} = R(t_{2l} - t_1) - R(t_{2l-1} - t_1) = R(\xi - \xi_1 + \tau_1) - R(\xi - \xi_1 + \tau_1 - \tau_1 - \tau_1) \). Moreover, \( \Lambda_{0,1} = S(\xi - \xi_1 + \tau_1) + S(\xi - \xi_1 - \tau_1 - \tau_1 - \tau_1) - S(\xi - \xi_1) - S(\xi - \xi_1 + \tau_1) - S(\xi - \xi_1 + \tau_1 - \tau_1).

As before, it is more convenient to work now in the Laplace space, where many terms factorize. In fact, one can identify (see e.g. Fig. 9) products of one or several irreducible extended-NIBA kernels \((F(\lambda), \tilde{A}_{\delta}(\lambda))\) and \((F_0(\lambda))\) with one of the irreducible kernels containing inter-blip and blip-sojourn interactions \((\Sigma_{\delta}^{(n)}(\lambda), \Sigma_{\delta}^{(n)}(\lambda), \Sigma_{\delta}^{(n)}(\lambda))\). After exchanging the integration order as done in Eq. \((29)\), the probability difference reads.
in the Laplace space

\[ \dot{P}_{\text{WIBA}}(\lambda) = \dot{P}_{\text{EN}}(\lambda) \]

\[ + \frac{1}{\lambda} \sum_{n=2}^{\infty} \left\{ \prod_{l=2}^{n} \left[ \frac{n}{p} - \hat{F}(\lambda) \right] \left[ \hat{\Sigma}_{0,a} + \hat{\Sigma}_{0,s} \right]^{(l)} \right\} \]

\[ + \frac{1}{\lambda} \sum_{l=3}^{n-1} \left\{ \prod_{k=l+1}^{n} - \hat{F}(\lambda) \left[ \hat{\Sigma}_{s} \right]^{(l-k+1)} \right\} \times \prod_{j=2}^{k-1} - \hat{F}(\lambda) \left[ - \left( \hat{F}_{0}(\lambda) + \hat{A}_{0}(\lambda) \right) \right] \right\}. \] (55)

After some changes of variables, Eq. (55) can be recast in the form

\[ \dot{P}_{\text{WIBA}}(\lambda) = \dot{P}_{\text{EN}}(\lambda) \]

\[ + \frac{1}{\lambda} \sum_{m=0}^{\infty} \sum_{\gamma=0}^{m} \left\{ \left[ \hat{\Sigma}_{0,a} + \hat{\Sigma}_{0,s} \right]^{(m+2)} \left[ - \hat{F}(\lambda) \right]^{m-\gamma} \right\} \]

\[ + \left[ \hat{\Sigma}_{s} \right]^{(m+2)} \left[ - \hat{F}(\lambda) \right]^{m-\gamma} (m - \gamma + 1) \]

\[ \times \left[ - \left( \hat{F}_{0}(\lambda) + \hat{A}_{0}(\lambda) \right) \right] \right\}. \] (56)

which becomes, after noticing that \( \sum_{m=0}^{\infty} \sum_{\gamma=0}^{m} = \sum_{m=0}^{\infty} \sum_{\gamma=0}^{m} \sum_{m=0}^{\infty} \sum_{\gamma=0}^{\infty} \):\]

\[ \dot{P}_{\text{WIBA}}(\lambda) = \dot{P}_{\text{EN}}(\lambda) \]

\[ + \frac{1}{\lambda} \sum_{m=0}^{\infty} \left\{ \left[ \hat{\Sigma}_{0,a} + \hat{\Sigma}_{0,s} \right]^{(m+2)} \sum_{p=0}^{\infty} \left[ - \hat{F}(\lambda) \right]^{p} \right\} \]

\[ + \left[ \hat{\Sigma}_{s} \right]^{(m+2)} \sum_{p=0}^{\infty} \left[ - \hat{F}(\lambda) \right]^{p} (p + 1) \left[ - \left( \hat{F}_{0}(\lambda) + \hat{A}_{0}(\lambda) \right) \right] \right\}. \] (57)

It is convenient to introduce the irreducible kernels \( \hat{\Sigma}_{s} \equiv \sum_{m=0}^{\infty} \hat{\Sigma}_{s}(m+2) \) and \( \hat{\Sigma}_{0,a/s} \equiv \sum_{m=0}^{\infty} \hat{\Sigma}_{0,a/s}(m+2) \) obtained upon summing over the number of tunneling transitions. Thus, recalling the extended-NIBA expression \[ 28 \], we find

\[ \dot{P}_{\text{WIBA}}(\lambda) = \frac{1}{\lambda} + \frac{1}{\lambda} \left[ \frac{1}{\lambda} \left( \hat{F}_{0}(\lambda) + \hat{A}_{0}(\lambda) \right) \right] \]

\[ \times \sum_{m=0}^{\infty} \left[ - \hat{F}(\lambda) \right]^{m-1} \left[ - \hat{F}(\lambda) + m \hat{\Sigma}_{s}(\lambda) \right] \]

\[ \times \sum_{m=0}^{\infty} \left[ - \hat{F}(\lambda) \right]^{m-1} \left[ - \hat{F}(\lambda) + m \hat{\Sigma}_{s}(\lambda) \right] \] (58)

Keeping in mind that we should always retain the interactions \( \lambda \) and \( X \) up to the first order, Eq. (58) can be rearranged in a more compact form as

\[ \dot{P}_{\text{WIBA}}(\lambda) \approx \frac{1}{\lambda} + \frac{1}{\lambda} \left[ \frac{1}{\lambda} \left( \hat{F}_{0}(\lambda) + \hat{A}_{0}(\lambda) \right) \right] \]

\[ \times \sum_{m=0}^{\infty} \left[ - \hat{F}(\lambda) \right]^{m-1} \left[ - \hat{F}(\lambda) + m \hat{\Sigma}_{s}(\lambda) \right]. \] (59)

yielding

\[ \dot{P}_{\text{WIBA}}(\lambda) = \frac{1}{\lambda} \left[ 1 + \frac{1}{\lambda} \left( \hat{F}_{0}(\lambda) + \hat{A}_{0}(\lambda) \right) \right] \]

\[ \times \sum_{m=0}^{\infty} \left[ - \hat{F}(\lambda) \right]^{m-1} \left[ - \hat{F}(\lambda) + m \hat{\Sigma}_{s}(\lambda) \right]. \] (60)

where we introduced the functions

\[ \hat{K}_{\text{WIBA}}(\lambda) = \lambda \left[ \hat{F}(\lambda) - \hat{\Sigma}_{s}(\lambda) \right] \], \] (62a)

\[ \hat{K}_{0,\text{WIBA}}(\lambda) = \lambda \left[ \hat{A}_{0}(\lambda) - \hat{\Sigma}_{0,a}(\lambda) \right] \], \] (62b)

\[ \hat{K}_{s,\text{WIBA}}(\lambda) = \lambda \left[ \hat{F}_{0}(\lambda) - \hat{\Sigma}_{0,s}(\lambda) \right] \], \] (62c)

\[ \hat{W}_{\text{WIBA}}(\lambda) = \hat{K}_{\text{WIBA}}(\lambda) - \hat{K}_{0,\text{WIBA}}(\lambda). \] (62d)

B. Generalized master equation (GME) for the WIBA model

After multiplying both sides of Eq. (61) by \( \lambda + \hat{K}_{\text{WIBA}}^{s} \), one can recognize the Laplace transform of the generalized master equation Eq. (4), where from Eq. (62) the WIBA kernels in the time domain are

\[ K_{\text{WIBA}}(t) = \hat{F}(t) - \hat{\Sigma}_{s}(t) \], \] \[ K_{0,\text{WIBA}}(t) = \hat{F}_{0}(t) - \hat{\Sigma}_{0,s}(t) \], \] \[ K_{s,\text{WIBA}}(t) = \hat{A}_{0}(t) - \hat{\Sigma}_{0,a}(t) \], \] \[ W_{\text{WIBA}}(t) = K_{\text{WIBA}}(t) - K_{0,\text{WIBA}}(t) \]. \] (63)

The prescription [63] allows the explicit evaluation of the irreducible kernels. This procedure is illustrated in App. [63]. Explicitly, the antisymmetric WIBA kernel reads

\[ K_{s,\text{WIBA}}(\xi) = K_{s,\text{WIBA}}^{s}(\xi) \]

\[ - \int_{0}^{\xi} d\xi_{1} \int_{0}^{\xi_{1}} d\xi_{2} \hat{h}_{\text{en}}(\xi_{2}) p_{\text{en}}(\xi_{1} - \xi_{2} - \xi_{f}) \]

\[ \times [g_{\text{en}}(\xi_{1}) X_{f,0} - g_{\text{en}}(\xi_{1}) \lambda_{f,1}], \] (64)

where, as in the extended-NIBA case, cf. [63], corrections of order \( \hat{R}(\xi_{f}) \xi_{f}^{2} \) have been neglected. The functions \( g_{\text{en}}, h_{\text{en}} \) have been defined in [63]. Analogously, we also introduced here the functions

\[ \hat{g}_{\text{en}}(\xi_{j}) = \Delta^{2} e^{-S(\xi_{j})} \cos(\varepsilon_{\xi_{j}}) \sin[\hat{R}(\xi_{j})], \]

\[ \hat{h}_{\text{en}}(\xi_{j}) = \Delta^{2} e^{-S(\xi_{j})} \sin(\varepsilon_{\xi_{j}}) \cos[\hat{R}(\xi_{j})], \] (65)
with \( \tilde{R}(t) = R(t) - t\dot{R}(t) \). The symmetric WIBA kernel becomes

\[
K_{\text{WIBA}}^s(\xi) = K_{eN}^s(\xi) - \int_0^\xi d\xi_1 \int_0^{\xi-\xi_1} d\xi_f \tilde{h}_{eN}(\xi_f) p_eN(\xi - \xi_1 - \xi_f) \\
\times [\tilde{h}_{eN}(\xi_f)\Lambda_{f,1}] .
\]

(66)

The irreducible symmetric kernel is shown in Fig. 7. Moreover, the function \( W_{\text{WIBA}} \) is now given by

\[
W_{\text{WIBA}}(\xi) \equiv K^s_{\text{WIBA}}(\xi) - K^s_{0,\text{WIBA}}(\xi) ,
\]

(67)

where

\[
K^s_{0,\text{WIBA}}(\xi) = K^s_{eN}(\xi) - \int_0^\xi d\xi_1 \int_0^{\xi-\xi_1} d\xi_f \tilde{h}_{eN}(\xi_f) p_eN(\xi - \xi_1 - \xi_f) \\
\times [\tilde{h}_{N}(\xi_1)X_{f,0} + \tilde{h}_{N}(\xi_1)\Lambda_{f,1}] .
\]

(68)

In the Eqs. 64 and 68, \( X_{f,0} = R(\xi) - R(\xi - \xi_f) \), and for all the three kernels \( \Lambda_{f,1} = S(\xi) - S(\xi - \xi_1) + S(\xi - \xi_1 - \xi_f) - S(\xi - \xi_f) \).

C. Dynamics within the WIBA

Let us now come to the WIBA predictions. In this Section we will be showing the comparison of all the theories previously discussed, namely the NIBA, its extended version, the weak-coupling approximation (WCA) and our WIBA, for different choices of the parameters. In the following subsections we examine the behavior of \( P(t) \) in the case of Ohmic bath \( (s = 1) \) in the spectral density [5], with cutoff frequency \( \omega_c = 50\Delta \), and of super-Ohmic dissipative environment \( (we choose s = 3) \), for different choices of the frequencies \( \omega_c \) and \( \omega_{ph} \).

1. Ohmic case \( (s = 1) \)

We expect WIBA to work particularly well in the Ohmic case due to \( S(t) \sim t \) at long times. This has the simultaneous effect of suppressing the blip lengths and to yield a vanishing interblip interaction at large blip separation.

![FIG. 7: Irreducible symmetric WIBA kernel. Notice that the lowest order reproduces the extended-NIBA case, see Fig. 4. The inner bubble represents the contribution coming from the sum of all orders in \( \Delta^2 \) which coincides with the symmetric part of the solution of the master equation for \( P(t) \) in the extended-NIBA case.](image)

![FIG. 8: Time evolution of \( P(t) \) for an Ohmic symmetric two-state system. The WIBA (full lines) coincides with the NIBA (dashed lines) and the extended-NIBA (dotted lines) over the whole range of parameters. Here \( \alpha = 0.1 \) and \( T = 0.1 \) (in units of \( \Delta \)) have been chosen. For such a choice, the WCA (dot-dashed lines) slightly deviates from all other predictions.](image)

We first present (Fig. 8) the results for an Ohmic symmetric two-state system \( (\varepsilon = 0) \) for a generic choice of the parameters. For the symmetric case, the NIBA is expected to predict the correct time evolution over the whole range of coupling strengths and temperatures. One sees a complete agreement of the WIBA with the (extended-) NIBA. For the chosen parameters, also WCA well agrees with the WIBA predictions.

The situation becomes more intricate for the case of finite bias \( (\varepsilon \neq 0) \), since on the one hand NIBA is ex-
pected to fail at low temperatures and damping, while the WCA becomes inappropriate at large temperatures and/or damping. In the following, we fix the external bias as $\varepsilon = \Delta$.

Fig. 9 shows a case of low temperature $k_B T \leq E = \sqrt{\varepsilon^2 + \Delta^2}$ and small damping $\alpha$, namely $\alpha = 0.01$ and $T = 0.1$ (in units of $\Delta$). One can see that the agreement between WIBA and WCA is striking, whereas both NIBA and extended-NIBA fail to reach the correct asymptotic value, predicting an unphysical symmetry breaking.

In Figs. 10, 11 and 12 a comparison between WIBA and the numerical ab-initio path-integral approach (QUAPI) is made, in order to proof the validity of our theory in a regime of intermediate-to-high temperatures and coupling strength. As the coupling strength is raised to $\alpha = 0.1$ (Fig. 10), while keeping the temperature constant, one sees that the asymptote of the extended-NIBA is slowly moving from the NIBA one towards the QUAPI one. At the same time, the WCA also disagrees with the WIBA predictions, the former starting to be invalid for higher coupling strength. The WIBA, however, shows the presence of some unphysical “beatings” at the onset of the long-time dynamics, whose origin is not yet well understood. Hence, some more investigations seem to be required, in order to better understand the theory in this regime of parameters.

As one raises the coupling strength ($\alpha = 0.25$) (Fig. 11), by lowering the temperature ($T = 0.01$), one can observe that the WCA completely fails in predicting the right asymptote or the intermediate dynamics. The NIBA also predicts a wrong asymptotic value, while correctly describing the short-time dynamics. For such a choice of parameters, the extended-NIBA very well agrees with QUAPI, although some oscillations are still present in the theory. The WIBA also smoothly oscillates close to the QUAPI predictions.

Finally, Fig. 12 shows that, for the parameters $\alpha = 0.25$, $T = 0.01$, the WIBA and the extended-NIBA are almost indistinguishable from the QUAPI predictions. The WCA and the NIBA fail to describe the dynamics, even though the NIBA correctly reproduces the short-time dynamics. By looking at Figs. 10, 11 and 12 it is interesting to notice that the WIBA predicts more coherence than QUAPI. The overall agreement with QUAPI though remains very good.

Hence, we showed that WIBA works very well for
strong damping and/or high temperatures and small coupling strength and/or low temperatures, where is able to reproduce previous perturbative theories. In an intermediate regime of parameters, WIBA is shown to give an appropriate description of the dynamics.

2. Super-Ohmic case ($s = 3$)

Let us now consider the predictions of the WIBA in presence of a super-Ohmic bath. We choose to show here a very common situation, corresponding to $s = 3$. In contrast to the Ohmic case, analyzed above, for the super-Ohmic case is unclear if the WIBA can perform well over a broad regime of parameters. In fact, since $S(t \sim \Delta^{-1})$ differs only little from its asymptotic value $S(t \to \infty)$, the interblip interactions are weak and the WCA is expected to be a good approximation in a wide regime of parameters. This also implies that $S(t)$ is not effective in suppressing long-blip lengths and the NIBA might not be justified. Notice that we expect WIBA to work well in all the situations such that $1 < s < 2$, since for those parameters the function $S(t)$ increases with time.

In the following figures, we keep temperature, external bias and coupling constant fixed ($T = 0.1$, $\varepsilon = 1$, $\delta_3 = 0.01$, in units of $\Delta$), while keeping the ratio $\omega_c/\omega_{ph}$ constant ($\omega_c/\omega_{ph} = 8$). This choice is reasonable and agrees with some experiments. The ratio $\omega_c/\omega_{ph}$ acts as an effective correction factor to the real coupling strength, see Eqs. (10) and (11). Moreover, since we fix the temperature, in the bath correlation function corrections proportional to the temperature ($k = 1/\hbar\beta\omega_c$) become important as the cutoff frequency is decreased.

In Fig. 13 the cutoff frequency $\omega_c = 200$ is assumed to be very large compared to the system frequency scales. There, one sees that the WIBA well matches the WCA predictions, as expected in the regime of weak damping.

On the other hand, Fig. 14 shows the WIBA predictions for $P(t)$ when the cutoff frequency $\omega_c$ is of the order of the tunneling frequency $\Delta$, namely when the bath becomes “slow”, a case where the WCA and the NIBA are expected to fail. This case is the most difficult one, since the bath is very coherent and memory effects are to be taken into account, which requires to perform a very good description of the full bath dynamics. One sees that the NIBA completely fails to reproduce the dynamics, even reaching unphysical values. The extended-NIBA works better, approaching closer the QUAPI predictions. Nevertheless, too few correlations are taken into account, and it oscillates still too much with respect to the numerical plot of QUAPI. The WIBA shows discrepancies from the QUAPI as well, being still “too” coherent, even though its predictions are more accurate than the extended-NIBA. The WCA, despite better than WIBA in this regime, also lie apart from the numerical prediction of QUAPI. In this range of parameters, the temperature-dependent corrections in the bath correlation function $Q$ become relevant and the perturbative weak-coupling approach begins to fail. Thus, more analysis of the complicated super-Ohmic case is to be done, in order to better understand the different dynamical situations which take place by varying the coupling strength $\delta_3$, the cutoff frequency $\omega_c$ and the phonon frequency $\omega_{ph}$.

![FIG. 13: Time evolution of $P(t)$ for $\delta_3 = 0.01$, $\omega_c = 200$ ($T = 0.1$, $\varepsilon = 1$). Here one sees no difference between WCA (dot-dashed lines) and WIBA (full lines), showing that the chosen parameters lie in an effective weak-coupling regime.](image1.png)

![FIG. 14: Time evolution of $P(t)$ for $\delta_3 = 0.01$, $\omega_c = 1$ ($T = 0.1$, $\varepsilon = 1$). Here we notice discrepancies between WIBA (full lines) and QUAPI (full lines with bullets), since the extended-NIBA predictions (dotted lines) also account for too many oscillations. Nevertheless, it gives much better results than NIBA (dashed lines), predicting unphysical values for $P(t)$. Finally, the WCA (dot-dashed lines) is so far the best model in this regime, although it lies apart as well from the QUAPI predictions, since the perturbative approach for such parameters begins to fail.](image2.png)
VI. CONCLUSIONS

To conclude, we presented here a novel analytical scheme dubbed WIBA (Weakly-Interacting Blip Approximation) which is able to match between diverse approximation schemes for different parameters choices. In particular, the WIBA is valid over a large regime of temperatures and coupling strength for a wide class of spectral densities. The WIBA reproduces very well weak-coupling approximation schemes for small damping and temperature and the well-known NIBA in the opposite regime of strong damping and high temperature. It yields a good, though not perfect agreement, with ab-initio QUAPI calculation in the regime of intermediate temperatures and damping. Hence, the WIBA overcomes the dim validity of the perturbative approaches discussed in the previous Sections which, up to now, was only possible via numerical ab-initio schemes. It also serves as benchmark to limiting simple analytical schemes, in order to proof their range of applicability over the various regimes, and combine weak-coupling and strong-damping approaches in one single, unified model.

Our approach is based on the consideration that bath-induced blip-blip and blip-sojourn interactions are weak in the whole range of parameters for the spectral densities. It is especially needed in several contexts, and we mention here few of them: i) The WIBA could be very useful when experimentally the bath temperature or the external bias are varied over a wide range: In fact, WCA and NIBA are unreliable at high temperatures and/or super-Ohmic damping, NIBA is expected to be a good approximation whenever the average time spent in a blip is much larger than the time spent in a sojourn.

In general, the inter-dipole interaction can be safely neglected for all temperatures for sub-Ohmic damping, NIBA is expected to be a good approximation even for very small coupling \(\delta_s\). For Ohmic and super-Ohmic damping, NIBA is expected to be a good approximation at high enough temperature and/or strong damping. In particular, spectral densities of the Ohmic form reach for large temperatures faster the asymptotic behavior \(S(t) \propto t\) at long times, implying that the correlations in \(\Lambda_{j,k}\) cancel out exactly.

APPENDIX A: DERIVATION OF THE NIBA KERNELS

In the non-interacting blip approximation, as mentioned in the Sec. \[\text{IV}\], one neglects all blip-blip correlations and blip-sojourn interactions in Eq. \[\text{10}\], i.e. \(\Phi_{\text{inter}}^{(a)} = 0\). The blip-preceeding-sojourn interactions are neglected as well \(\Phi_{\text{bbs}}^{(a)} = 0\), i.e. one sets \(X_{j,j-1} \approx R_{2j,2j-1}\). As a consequence, the influence function \[\text{12}\] factorizes into individual influence factors depending only on the dipole length \(\tau_j := t_{2j} - t_{2j-1}\). Following an analogous procedure as in Sec. \[\text{IV}\text{A}\] the NIBA series expression can be derived, and the corresponding GME, of the same form as in Eq. \[\text{33}\], is obtained. The kernels finally read

\[
\begin{align*}
K_N^s(t) &= \Delta^2 e^{-S(t)} \cos(zt) \cos[R(t)] , \\
K_N^s(t) &= \Delta^2 e^{-S(t)} \sin(zt) \sin[R(t)] , \\
K_{0,N}^s(t) &= \Delta^2 e^{-S(t)} \cos(zt) \cos[R(t)] , \\
W_N(t) &= K_N^s(t) - K_{0,N}^s(t) = 0 .
\end{align*}
\]

The kernels are of lowest order in the tunneling matrix \(\Delta\) but are non-perturbative in \(\delta_s\). The NIBA is expected to be a good approximation whenever the average time spent in a blip is much larger than the time spent in a sojourn.

In general, the inter-dipole interaction can be safely neglected for all temperatures for sub-Ohmic damping \(s < 1\), and the TLS is expected to exhibit incoherent dynamics even for very small coupling \(\delta_s\). For Ohmic and super-Ohmic damping, NIBA is expected to be a good approximation at high enough temperature and/or strong damping. In particular, spectral densities of the Ohmic form reach for large temperatures faster the asymptotic behavior \(S(t) \propto t\) at long times, implying that the correlations in \(\Lambda_{j,k}\) cancel out exactly.

APPENDIX B: EVALUATION OF THE WIBA KERNELS

In this Appendix, the prescription \[\text{B3}\] to evaluate the WIBA kernels in the time domain is illustrated. Let us consider, to fix the ideas, \(\Sigma_{0,\varphi}(\xi) = \sum_{l} \Sigma_{l,0}^{(l)}(\xi)\). The kernel \(\Sigma_{l,0}^{(l)}\), given in Eq. \[\text{53}\], is reported here for clarity:

\[
\Sigma_{l,0}^{(l)}(\xi) = \int_{0}^{\xi} d\xi_1 \int_{0}^{\xi - \xi_1} d\xi_2 \gamma_{\beta_1}(\xi_1) f(\xi - \xi_1 - \xi_2) \times [\gamma_{\beta_1}(\xi_1) X_{l,0} - \gamma_{\beta_1}(\xi_1) \Lambda_{l,1}] ,
\]

with \(X_{l,0} = R(\xi - \xi_1 + \tau_l) - R(\xi - \xi_1 + \tau_l - \tau_l)\). Notice that the operators \(\gamma\)‘s depend on the functions \(g / \bar{g} (h / \bar{h})\) defined in Eqs. \[\text{14}\] and \[\text{15}\].

In the function \(f(s)\) which appears in the expression for the kernel (see Eq. \[\text{53}\]), the first derivative of the conditional probability \(p_{\text{cN}}^{(l-2)}(s)\) is present. Then, it could
be integrated out by parts, obtaining

\[ \Sigma_{0,a}^{(l)}(\xi) = \int_0^\xi \, d\xi_1 \int_0^{\xi-\xi_1} \, d\xi \, \gamma_{\hat{h}}(\xi_1) \]

\[ \times p_{eN}^{(l-2)} (\xi - \xi_1 - \xi_2) [\gamma_{g_1}(\xi_1) X_{l,0} - \gamma_{\bar{g}_1}(\xi_1) \Lambda_{l,1}] , \]

(B2)

Here, the first derivative of the operator \( \gamma_{\hat{h}}(\xi_1) \) acts on the functions \( X_{l,0} = R(\xi - \xi_1 + \tau_1) - R(\xi - \xi_1 + \tau_1 + \tau) \) and \( \Lambda_{l,1} = S(\xi - \xi_1 + \tau_1) + S(\xi - \xi_1 - \tau) - S(\xi - \xi_1) - S(\xi - \xi_1 + \tau_1 - \tau_1) \) as

\[ \gamma_{\hat{h}}(\xi_1) X_{l,0} \]

\[ = \partial_{\xi_1} \int_0^{\xi_1} \, d\tau_1 \, \bar{h}(\xi_1, \xi_1 - \tau_1) X_{l,0} \]

\[ \approx \partial_{\xi} \int_0^{\xi_1} \, d\tau_1 \, \bar{h}(\xi_1, \xi_1 - \tau_1) X_{l,0} \]

\[ = \bar{h}_{eN}(\xi_1) [R(\xi - \xi_1 + \tau_1) - R(\xi - \xi_1 + \tau_1 - \tau_1)] , \]

(B3)

and

\[ \gamma_{\hat{h}}(\xi_1) \Lambda_{l,1} \]

\[ = \partial_{\xi_1} \int_0^{\xi_1} \, d\tau_1 \, \bar{h}(\xi_1, \xi_1 - \tau_1) \Lambda_{l,1} \]

\[ \approx \partial_{\xi} \int_0^{\xi_1} \, d\tau_1 \, \bar{h}(\xi_1, \xi_1 - \tau_1) \Lambda_{l,1} \]

\[ = \bar{h}_{eN}(\xi_1) \left[ S(\xi - \xi_1 + \tau_1) + S(\xi - \xi_1 - \tau) - S(\xi - \xi_1) - S(\xi - \xi_1 + \tau_1 - \tau) \right] . \]

As already observed when calculating the extended-NIBA kernels, the explicit dependence of the integrand of Eq. (B3) on \( \xi \) yields an integral form for \( \gamma_{\hat{h}}(\xi) X_{l,0} \).

An approximate form is obtained if we apply the same prescription as for the extended-NIBA. Namely, one approximates the bath correlation differences in \( \bar{y}_{j-1} \) with the first derivative of \( R(t) \). Hence, for \( g \) and \( h \) Eq. (B4) holds, whereas for \( \bar{y} \) and \( \bar{h} \) it follows \((l > 1)\)

\[ \bar{y}(\tau, \xi_1 - \tau) \approx \bar{y}(\tau, \xi_1) \]

\[ = \Delta^2 \text{e}^{-S(\tau)} \cos(\varepsilon \tau) \sin[R(\tau) - \tau \hat{R}(\xi_1)] , \]

\[ \bar{h}(\tau, \xi_1 - \tau) \approx \bar{h}(\tau, \xi_1) \]

\[ = \Delta^2 \text{e}^{-S(\tau)} \sin(\varepsilon \tau) \cos[R(\tau) - \tau \hat{R}(\xi_1)] , \]

(B5)

the corrections being of order \( O[\tau^2 \hat{R}(\xi_1)] \). We define \( \bar{y}_{eN}(\xi) \equiv \bar{y}(\xi, \xi) \) and \( \bar{h}_{eN}(\xi) \equiv \bar{h}(\xi, \xi) \).

In order to evaluate the antisymmetric WIBA kernel \( K^{\sigma}_{\text{WIBA}} \) from the prescription (B3), one sees that the previous expression must be derived with respect to \( \xi \). After substituting \( u \equiv \xi - \xi_1 \) in the Eq. (B2), we get

\[ \Sigma_{0,a}^{(l)}(\xi) = \int_0^\xi \, du \int_0^{u} \, d\xi \, \bar{h}_{eN}(\xi) \]

\[ \times p_{eN}^{(l-2)} (u - \xi_1) [\gamma_{g_1}(\xi - u) X_{l,0} - \gamma_{\bar{g}_1}(\xi - u) \Lambda_{l,1}] , \]

(B6)

with \( X_{l,0} = R(u + \tau_1) - R(u + \tau_1 + \tau_1) \) and \( \Lambda_{l,1} = S(u + \tau_1 + \tau_1) + S(u + \tau_1 - \tau) - S(u) - S(u + \tau_1 + \tau) \).

Then, in order to get the derivative of \( \Sigma_{0,a}^{(l)}(\xi) \) with respect to \( \xi \), it is enough to evaluate

\[ \partial_\xi [\gamma_{g_1}(\xi - u) X_{l,0} - \gamma_{\bar{g}_1}(\xi - u) \Lambda_{l,1}] \]

\[ = \partial_\xi \int_0^{\xi-u} \, d\tau_1 [g_1(\tau_1, s_0 \to \infty) X_{l,0} - \bar{g}_1(\tau_1, s_0 \to \infty) \Lambda_{l,1}] \]

\[ = g_N(\xi - u) X_{l,0} - \bar{g}_N(\xi - u) \Lambda_{l,1} , \]

(B7)

where now \( X_{l,0} = R(\xi) - R(\xi - \xi_1) \) and \( \Lambda_{l,1} = S(\xi) + S(\xi - \xi_1 - \tau) - S(\xi - \xi_1) - S(\xi - \xi_1) . \)

Hence, we obtain for the \( l \)-th order (after the derivative, we substitute back \( \xi \equiv \xi - u \))

\[ \partial_\xi \Sigma_{0,a}^{(l)}(\xi) \]

\[ = \int_0^\xi \, d\xi_1 \int_0^{\xi-\xi_1} \, d\xi_2 \, \bar{h}_{eN}(\xi_1) p_{eN}(\xi - \xi_2) \]

\[ \times [g_N(\xi_1) X_{l,0} - \bar{g}_N(\xi_1) \Lambda_{l,1}] , \]

(B8)

In the end, the antisymmetric WIBA kernel reads

\[ K^{\sigma}_{\text{WIBA}}(\xi) \equiv K^{a}_{\text{eN}}(\xi) - \sum_{\sigma=2}^{\infty} K^{a}_{\text{WIBA}}(\sigma)(\xi) \]

\[ = K^{a}_{\text{eN}}(\xi) \]

\[ - \int_0^\xi \, d\xi_1 \int_0^{\xi-\xi_1} \, d\xi_2 \, \bar{h}_{eN}(\xi_1) p_{eN}(\xi - \xi_1 - \xi_2) \]

\[ \times [g_N(\xi_1) X_{l,0} - \bar{g}_N(\xi_1) \Lambda_{l,1}] , \]

(B9)

where we introduced \( p_{eN}(t) \equiv \sum_{\sigma=2}^{\infty} p_{eN}^{(\sigma-2)}(t) \). Following similar lines, we obtain for the symmetric WIBA kernels:

\[ K^{s}_{\text{WIBA}}(\xi) \equiv K^{a}_{\text{eN}}(\xi) - \sum_{\sigma=2}^{\infty} K^{a}_{\text{WIBA}}(\sigma)(\xi) \]

\[ = K^{a}_{\text{eN}}(\xi) \]

\[ - \int_0^\xi \, d\xi_1 \int_0^{\xi-\xi_1} \, d\xi_2 \, \bar{h}_{eN}(\xi_1) p_{eN}(\xi - \xi_1 - \xi_2) \]

\[ \times [h_N(\xi_1) X_{l,0} + \bar{h}_N(\xi_1) \Lambda_{l,1}] , \]

(B10)

and

\[ K^{s}_{\text{WIBA}}(\xi) \equiv K^{a}_{\text{eN}}(\xi) - \sum_{\sigma=2}^{\infty} K^{a}_{\text{WIBA}}(\sigma)(\xi) \]

\[ = K^{a}_{\text{eN}}(\xi) \]

\[ - \int_0^\xi \, d\xi_1 \int_0^{\xi-\xi_1} \, d\xi_2 \, \bar{h}_{eN}(\xi_1) p_{eN}(\xi - \xi_1 - \xi_2) \]

\[ \times [h_N(\xi_1) X_{l,0} + \bar{h}_N(\xi_1) \Lambda_{l,1}] , \]

(B11)

We identified in all equations the last time interval with \( \tau_f \) and correspondingly \( \xi_f \). In this last equation, we also
identified the first time interval $\tau_k$ with $\tau_1$ (therefore $\xi_k$ with $\xi_1$) and $\Lambda_{f,k}$ with $\Lambda_{f,1}$.

In Eqs. (159) and (160), $X_{f,0} = R(\xi) - R(\xi - \xi_f)$, and for all the three kernels $\Lambda_{f,1} = S(\xi) + S(\xi - \xi_1 - \xi_f) - S(\xi - \xi_1) - S(\xi - \xi_f)$. In Eq. (161), the term proportional to $X_{f,0}$ is absent because it vanishes after the integration by parts and the derivative, since it does not depend on $s_0$.
