We argue that the T-duality phenomenon is not exclusively a stringy effect but it is relevant also in the context of the standard point particle dynamics. To illustrate the point, we construct a four-parametric family of four-dimensional electro-gravitational backgrounds such that the dynamics of a charged point particle in those backgrounds is insensitive to a particular permutation of the parameters although this very permutation does alter the background geometry. In particular, we find that a direct product of the Euclidean plane with the two-dimensional Euclidean black hole admits a point-particle T-dual with asymptotically negative curvature. For neutral particles, this point-particle T-duality picture gets slightly modified because the T-duality map is no longer defined everywhere but only on a dense open domain of the space of states. The exceptional states sitting outside of the domain of definition can be then naturally interpreted in terms of a point particle T-fold.

1 Introduction

T-duality in string theory is a phenomenon relating two geometrically inequivalent Kalb-Ramond-gravitational backgrounds via the dynamics of strings. Speaking more precisely, T-duality takes place when a string moving in a background \((G, B)\) is dynamically equivalent to the string moving in the dual background \((\tilde{G}, \tilde{B})\) even though the backgrounds \((G, B)\) and \((\tilde{G}, \tilde{B})\) are not geometrically equivalent. Here by the "dynamical equivalence" is meant the existence of a canonical transformation transforming the Hamiltonian equations of motion of the string in the background \((G, B)\) into its Hamiltonian equations in the background \((\tilde{G}, \tilde{B})\). In mathematical terminology, the T-duality between two inequivalent target geometries \((G, B)\) and \((\tilde{G}, \tilde{B})\) is thus established if the phase space \(P\) of the string moving in \((G, B)\) is symplectomorphic to the phase space \(\tilde{P}\) of the string moving in \((\tilde{G}, \tilde{B})\).
and this symplectomorphism transforms the original Hamiltonian $H$ of the string into the dual one $\tilde{H}$.

A point-particle analogue of the stringy Kalb-Ramond-gravitational background $(G, B)$ is naturally an electromagnetic-gravitational background $(G, A)$. Indeed, locally speaking, while string world-sheet couples naturally to the Kalb-Ramond two-form field $B$, the point-particle world-line couples naturally to the one-form field $A$ interpreted as the electromagnetic potential. It is now evident what should be meant be the T-duality in the point-particle context. Indeed, we shall say that two geometrically inequivalent electromagnetic-gravitational backgrounds $(G, A)$ and $(\tilde{G}, \tilde{A})$ are T-dual to each other if there exists a canonical transformation transforming the point-particle Hamiltonian equations of motion in the background $(G, A)$ into the Hamiltonian equations of motion in the background $(\tilde{G}, \tilde{A})$. The main result of the present article is the construction of the four-parametric family of explicit examples of such T-dual pairs of dynamically equivalent but geometrically inequivalent electromagnetic-gravitational backgrounds in four dimensions.

It appears that the point-particle T-duality has not been so far suspected to exist. This is probably due to the fact that there are no winding modes for point particles which could be exchanged with the momentum modes. On the other hand, after the discovery of the Abelian T-duality with its momentum-winding exchange [8, 11], more general T-dualities have been proposed in the framework of string theory Ref. [5, 4, 3, 9] for which the question of the momentum winding exchange is not the central one (although it still can be posed, cf. Ref. [10]). In fact, what really matters for the T-duality to take place is the issue of the existence of the canonical transformation relating the phase spaces associated to geometrically inequivalent backgrounds. With this shift of perspective, the question of the existence of T-duality in the point particle dynamics should be treated without prejudices and our result presented in this article should therefore look less surprising.

It is perhaps worth mentioning that our construction of the point-particle T-duality examples is the fruits of a combination of a conceptual approach and of educated guesses. Conceptually, we have taken a lot of inspiration by exploring the symplectic geometries of the so called Drinfeld doubles which are Lie groups endowed with suitable symplectic forms. Such doubles have structures with certain (i.e. Poisson-Lie) dualities built in by construction, however, all point-particle T-duality examples which we constructed by considering various Drinfeld doubles suffered from the pathology that the dualizable Hamiltonian did not provide a complete flow on the domain of definition of the duality canonical transformation. Fortunately, we were able to cure some of those pathological examples "by hand", loosing of course the Drinfeld double interpretation but gaining the full-fledged, healthy and globally holding examples of the point-particle T-duality.

The plan of the article is as follows. In Section 2, we study in detail the basic building block of our T-dualizable four-dimensional backgrounds which is certain two-parameter deformation of the Euclidean black hole in two dimensions [14]. In Section 3, we consider the direct product of two deformed black holes and we
add to it a judiciously chosen background electric field. Then we describe the explicit canonical transformation relating this electro-gravitational background to its T-dual background, which is obtained by a suitable permutation of the four deformation parameters. We also prove that the original and the dual backgrounds are inequivalent as the Riemannian manifolds. In Section 4, we suppress the background electric field and we find that the T-duality symplectomorphism is then only defined on a dense open subset of the phase space. However, we succeed to interpret the exceptional points outside of this open subset in terms of a point-particle analogue of the T-fold geometry known in string theory [7]. In Section 5, we provide conclusions and an outlook.

2 Deformed black hole geometry

Consider the standard polar coordinates \(r, \phi\) on the plane \(\mathbb{R}^2\) and a two-parametric family of Riemannian metrics

\[
 ds^2 = \frac{1}{1 + \mu^2 r^2} dr^2 + \frac{r^2}{1 + \gamma^2 r^2} d\phi^2. \tag{1}
\]

Whatever are the values of the parameters \(\mu\) and \(\gamma\), this metric exhibits no curvature singularity, because its Ricci scalar reads

\[
 Ric = \frac{4\mu^2}{1 + \gamma^2 r^2} + \frac{6(\gamma^2 - \mu^2)}{(1 + \gamma^2 r^2)^2}. \tag{2}
\]

The geometry (1) is asymptotically flat except for the case \(\gamma^2 = 0\), for which we obtain the hyperbolic space of constant negative curvature. If \(\gamma^2 = \mu^2 = 1\), we recognize in the formula (1) the well-known Euclidean black-hole metric [14].

Consider an electric scalar potential

\[
 \varphi(r) = \frac{1}{2} \left( \frac{\gamma^2}{r^2} + 1 \right). \tag{3}
\]

The first order Hamiltonian dynamics of a charged point particle of a charge \(a^2\) in the geometry (1) and in the electric potential (3) (no magnetic field!) takes then place in the phase space \(P_a\), parametrized with the Darboux variables \(p_r, r > 0, p_\phi, \phi\). The Hamiltonian reads

\[
 H_a = \frac{1}{2} g^{jk}(r)p_j p_k + \varphi(r) = \frac{1}{2}(1 + \mu^2 r^2)p_r^2 + \frac{1}{2} \left( \gamma^2 + \frac{1}{r^2} \right) \left( p_\phi^2 + a^2 \right) \tag{4}
\]

and the symplectic form is

\[
 \omega = p_r \wedge dr + p_\phi \wedge d\phi. \tag{5}
\]

In particular, the corresponding Hamiltonian equations of motion read

\[
 \dot{p}_r = -r \mu^2 p_r^2 + \frac{p_\phi^2 + a^2}{r^3}, \quad \dot{r} = (1 + \mu^2 r^2)p_r, \quad \dot{\phi} = \left( \gamma^2 + \frac{1}{r^2} \right) p_\phi, \quad \dot{p}_\phi = 0. \tag{6}
\]
A general solution of these equations depends on four real parameters \( \zeta \in [0, 2\pi[, \kappa > 0, p_\phi, \nu \) and it reads

\[
\begin{align*}
  r(t)^2 &= \left( \frac{p_\phi^2 + a^2}{\kappa^2} + \frac{1}{\mu^2} \right) \cosh^2 (\kappa \mu (t + \nu)) - \frac{1}{\mu^2}, \\
  p_r(t) r(t) &= \frac{\kappa}{\mu} \tanh (\kappa \mu (t + \nu)), \\
  \phi(t) &= \zeta + \gamma^2 p_\phi t + \frac{p_\phi}{\sqrt{p_\phi^2 + a^2}} \arctan \left( \frac{\kappa \tanh (\kappa \mu (t + \nu))}{\mu \sqrt{p_\phi^2 + a^2}} \right).
\end{align*}
\]  

(7a)

(7b)

(7c)

We observe that for all possible values of the parameters \( \zeta, \kappa, p_\phi, \nu \) the solution (7) of the equation of motions is \emph{complete}, which means that it avoids the singularity \( r = 0 \) and it does not arrive at infinity in a finite time \( t \). We thus conclude that the Hamiltonian (4) is non-pathological.

### 3 \ T-duality as canonical transformation

Consider a four-parametric four-dimensional background \( T(\mu, \gamma, m, c) \) obtained as the direct product of two deformed black holes (1) with the added electric potentials

\[
\begin{align*}
  ds^2 &= \frac{1}{1 + \mu^2 r^2} dr^2 + \frac{r^2}{1 + \gamma^2 r^2} d\phi^2 + \frac{1}{1 + m^2 \rho^2} d\rho^2 + \frac{\rho^2}{1 + c^2 \rho^2} df^2, \\
  \varphi &= \frac{1}{2} \left( \gamma^2 + \frac{1}{r^2} \right) + \frac{1}{2} \left( c^2 + \frac{1}{\rho^2} \right).
\end{align*}
\]  

(8a)

(8b)

The dynamics of the charged point particle of the positive charge \( a^2 \) in the background \( T(\mu, \gamma, m, c) \) is then governed by the Hamiltonian

\[
H_{aX} = \frac{1}{2} \left( 1 + \mu^2 r^2 \right) p_r^2 + \frac{1 + \gamma^2 r^2}{2 r^2} (p_\phi^2 + a^2) + \frac{1}{2} \left( 1 + m^2 \rho^2 \right) p_\rho^2 + \frac{1 + c^2 \rho^2}{2 \rho^2} (p_f^2 + a^2)
\]  

(9)

and by the symplectic form

\[
\omega_X = p_r \wedge dr + p_\phi \wedge d\phi + p_\rho \wedge d\rho + p_f \wedge df.
\]  

(10)
We now express the coordinates \( p_r, r > 0, p_\rho, \rho > 0, p_\phi, \phi, p_f, f \) on the phase space \( P_{a\times} \) in terms of new coordinates \( P_R, R > 0, P_\mathcal{R}, \mathcal{R} > 0, P_\Phi, \Phi, P_F, F \) as follows

\[
\begin{align*}
   r &= R \sqrt{\frac{R^2 P_R^2 + P_\Phi^2 + a^2}{R^2 P_R^2 + P_F^2 + a^2}}, &
   p_r &= P_R \sqrt{\frac{R^2 P_R^2 + P_F^2 + a^2}{R^2 P_R^2 + P_\Phi^2 + a^2}}, &
   p_\phi &= P_\Phi, & (11a) \\
   \rho &= R \sqrt{\frac{R^2 P_R^2 + P_F^2 + a^2}{R^2 P_R^2 + P_\Phi^2 + a^2}}, &
   p_\rho &= P_R \sqrt{\frac{R^2 P_R^2 + P_\Phi^2 + a^2}{R^2 P_R^2 + P_F^2 + a^2}}, &
   p_f &= P_F, & (11b) \\
   f &= F + \frac{P_F}{\sqrt{P_F^2 + a^2}} \arctan \left( \frac{R P_R}{\sqrt{P_F^2 + a^2}} \right) - \frac{P_F}{\sqrt{P_F^2 + a^2}} \arctan \left( \frac{\mathcal{R} P_\mathcal{R}}{\sqrt{P_F^2 + a^2}} \right), & (11c) \\
   \phi &= \Phi - \frac{P_\Phi}{\sqrt{P_\Phi^2 + a^2}} \arctan \left( \frac{R P_R}{\sqrt{P_\Phi^2 + a^2}} \right) + \frac{P_\Phi}{\sqrt{P_\Phi^2 + a^2}} \arctan \left( \frac{\mathcal{R} P_\mathcal{R}}{\sqrt{P_\Phi^2 + a^2}} \right). & (11d)
\end{align*}
\]

The transformation (11) is the diffeomorphism of the phase space \( P_{a\times} \) with the inverse diffeomorphism given by

\[
\begin{align*}
   R &= \rho \sqrt{\frac{\rho^2 p_\rho^2 + p_\phi^2 + a^2}{\rho^2 p_\rho^2 + p_F^2 + a^2}}, &
   P_R &= p_\rho \sqrt{\frac{\rho^2 p_\rho^2 + p_F^2 + a^2}{\rho^2 p_\rho^2 + p_\phi^2 + a^2}}, &
   P_\Phi &= p_\phi, & (12a) \\
   \mathcal{R} &= r \sqrt{\frac{r^2 p_r^2 + p_\phi^2 + a^2}{r^2 p_r^2 + p_\rho^2 + a^2}}, &
   P_\mathcal{R} &= p_r \sqrt{\frac{r^2 p_r^2 + p_\rho^2 + a^2}{r^2 p_r^2 + p_\phi^2 + a^2}}, &
   P_F &= p_f, & (12b) \\
   F &= f - \frac{p_f}{\sqrt{p_F^2 + a^2}} \arctan \left( \frac{\rho p_\rho}{\sqrt{p_F^2 + a^2}} \right) + \frac{p_f}{\sqrt{p_F^2 + a^2}} \arctan \left( \frac{r p_r}{\sqrt{p_F^2 + a^2}} \right), & (12c) \\
   \Phi &= \phi + \frac{p_\phi}{\sqrt{p_\phi^2 + a^2}} \arctan \left( \frac{\rho p_\rho}{\sqrt{p_\phi^2 + a^2}} \right) - \frac{p_\phi}{\sqrt{p_\phi^2 + a^2}} \arctan \left( \frac{r p_r}{\sqrt{p_\phi^2 + a^2}} \right). & (12d)
\end{align*}
\]

Moreover, the transformation (11) is the symplectic diffeomorphism (or symplectomorphism) of the phase space \( P_{a\times} \) because it preserves the symplectic form \( \omega_x \). Indeed, inserting the formulas (11) into (10) gives

\[
\omega_x = dP_R \wedge dR + dP_\Phi \wedge d\Phi + dP_\mathcal{R} \wedge d\mathcal{R} + dP_F \wedge dF. \quad (13)
\]

It remains to show that the canonical transformation (11) can be interpreted as the T-duality symplectomorphism. For that, we express the Hamiltonian (9) in terms of the new Darboux coordinates \( P_R, R > 0, P_\mathcal{R}, \mathcal{R} > 0, P_\Phi, \Phi, P_F, F \). The
result is

\[ H_{ax} = \frac{1}{2}(1 + m^2 R^2) P_R^2 + \frac{1 + \gamma^2 R^2}{2 R^2} (P_\Phi^2 + a^2) + \frac{1}{2} (1 + \mu^2 R^2) P_R^2 + \frac{1 + c^2 R^2}{2 R^2} (P_\Phi^2 + a^2). \]  

(14)

The comparison of the formula (14) with (9) shows that the role of the parameters \( m \) and \( \mu \) got exchanged while the parameters \( c \) and \( \gamma \) remained in their places. Said in other words, the Hamiltonian (14) describes the dynamics of the charged point particle in the dual background \( \tilde{T}(m, \gamma, \mu, c) \)

\[ \tilde{d}s_x^2 = \frac{1}{1 + m^2 R^2} dR^2 + \frac{R^2}{1 + \gamma^2 R^2} d\phi^2 + \frac{1}{1 + \mu^2 R^2} dR^2 + \frac{\mathcal{R}^2}{1 + c^2 R^2} dF^2, \]  

(15a)

\[ \tilde{\varphi}_x = \frac{1}{2} \left( \gamma^2 + \frac{1}{R^2} \right) + \frac{1}{2} \left( c^2 + \frac{1}{\mathcal{R}^2} \right). \]  

(15b)

To conclude the argument, that this point-particle T-duality indeed does something non-trivial, it is sufficient to show that the flipping of the parameters \( \mu \) and \( m \) may alter the Riemannian geometry of the dual background \( \tilde{T}(m, \gamma, \mu, c) \) with respect to that of the original one \( T(\mu, \gamma, m, c) \). For that, consider for example the background \( T(0, 0, 1, 1) \) with the metric

\[ ds_x^2 = dr^2 + r^2 d\phi^2 + \frac{d\rho^2 + \rho^2 d\mathcal{F}^2}{1 + \rho^2}. \]  

(16)

We see that this is the Riemannian geometry of the direct product of the Euclidean plane with the Euclidean black hole [14]. The metric corresponding to the dual background \( \tilde{T}(1, 0, 0, 1) \) is

\[ \tilde{d}s^2 = \frac{1}{1 + \rho^2} dr^2 + r^2 d\phi^2 + d\rho^2 + \frac{\rho^2}{1 + \rho^2} d\mathcal{F}^2. \]  

(17)

Using the formula (2), we find easily the respective Ricci scalars of the metrics (16) and (17)

\[ Ric = \frac{4}{1 + \rho^2}, \quad \tilde{Ric} = -2 + \frac{6}{(1 + \rho^2)^2}. \]  

(18)

We thus observe that the Riemannian geometries (16) and (17) are inequivalent, because \( Ric \) is strictly positive while \( \tilde{Ric} \) acquires also negative values.

4 Point-particle T-fold

In this section, we shall discuss the dynamics of a neutral particle in the background \( T(\mu, \gamma, m, c) \). Since the charge \( a^2 \) vanishes, the electric potential plays no role and the background can be therefore considered as purely gravitational. We start our analysis with the two-dimensional metric (1) corresponding to the deformed Euclidean black hole

\[ ds^2 = \frac{1}{1 + \mu^2 r^2} dr^2 + \frac{r^2}{1 + \gamma^2 r^2} d\phi^2. \]  

(19)
The Hamiltonian of the neutral particle in the background (19) reads

\[ H = \frac{1}{2}(1 + \mu^2 r^2)p_r^2 + \frac{1}{2} \left( \gamma^2 + \frac{1}{r^2} \right) p_\phi^2 \]  
(20)

and the symplectic form is as before

\[ \omega = p_r \wedge dr + p_\phi \wedge d\phi. \]  
(21)

Now the neutral particle can reach the origin \( r = 0 \) because there is no repulsive electrostatic potential which could prevent it. This means that the neutral phase space \( P \) is slightly bigger than the charged one \( P_a \) and the coordinate chart \( p_r, r > 0, p_\phi, \phi \) does not cover it all, so we prefer rather to work with globally defined coordinates at the price that the rotational symmetry of the background will be less explicit. Thus, we introduce the metric on the plane \( \mathbb{R}^2 \) by the formula

\[ ds^2 = \frac{4 dx d\bar{x} + \gamma^2 (x dx - \bar{x} d\bar{x})^2 - \mu^2 (x dx + \bar{x} d\bar{x})^2}{4(1 + \gamma^2 x \bar{x})(1 + \mu^2 x \bar{x})}, \]  
(22)

where

\[ x = x^1 + ix^2, \quad \bar{x} = x^1 - ix^2 \]  
(23)

and \( x^1, x^2 \) are the standard global Cartesian coordinates on \( \mathbb{R}^2 \). Actually, the metric (22) is that (1) of the deformed black hole, as it is easy to verify by setting

\[ x = re^{i\phi}. \]  
(24)

As far as the corresponding neutral phase space \( P \) is concerned, it can be globally described as \( \mathbb{R}^4 \) covered by the complex Darboux coordinates \( x = x^1 + ix^2, \quad p = p_1 + ip_2 \), so that the symplectic form reads

\[ \omega = \frac{1}{2}(dp \wedge dx + dp \wedge d\bar{x}). \]  
(25)

The standard Hamiltonian is found by inverting the metric (22), which gives the formula

\[ H = \frac{1}{2} p \bar{p} + \frac{\mu^2}{8} (p \bar{x} + \bar{p} x)^2 - \frac{\gamma^2}{8} (p \bar{x} - \bar{p} x)^2. \]  
(26)

The Hamiltonian (26) and the symplectic form (25) give rise to the Hamiltonian (20) and the symplectic form (21), upon the canonical transformation

\[ x = re^{i\phi}, \quad p = \left( p_r + \frac{ip_\phi}{r} \right) e^{i\phi}. \]  
(27)

The equations of motion of the neutral particle in the coordinates \( x, p \) then read

\[ \dot{x} = p + \frac{\mu^2}{2} (p \bar{x} + \bar{p} x)x + \frac{\gamma^2}{2} (p \bar{x} - \bar{p} x)x, \]  
(28)
\[ \dot{p} = -\frac{\mu^2}{2}(p\bar{x} + \bar{p}x)p + \frac{\gamma^2}{2}(p\bar{x} - x\bar{p})p, \]  

(29)

and their general solution, depending on four real parameters \( \zeta \in [0, 2\pi] \), \( \kappa \geq 0 \), \( \nu, \lambda \), turns out to be

\[ x = e^{i(\zeta - \gamma^2\lambda\kappa t)} \left( \lambda \cosh (\mu\kappa(t + \nu)) - i\frac{\sinh (\mu\kappa(t + \nu))}{\mu} \right), \quad p = -i\kappa e^{i(\zeta - \gamma^2\lambda\kappa t)} \cosh (\mu\kappa(t + \nu)). \]  

(30)

Similarly as in the charged case, the solutions (30) are complete for all possible values of the parameters \( \zeta, \kappa, \nu, \lambda \), therefore the neutral Hamiltonian (20) is non-pathological.

What is crucial for the discussion in the present section is the fact that the Hamiltonian (20) stays non-pathological even if we cut out the points from the neutral phase space \( P \) for which the complex coordinate \( p \) vanishes. Indeed, looking at Eqs. (30), we observe that whenever a solution has a non-vanishing initial value \( p(t_0) \) it remains non-vanishing for all times \( t \). Thus we can define a restricted phase space

\[ P_r = \{(x, p) \in P; p \neq 0\}, \]  

(31)

with the symplectic form (25) and the Hamiltonian (20) (both understood as the restrictions of \( \omega \) and \( H \) to \( P_r \)).

Although the restricted dynamical system \((P_r, \omega_r, H_r)\) is complete, it lacks the geometrical interpretation because it misses that static solutions (30) with \( \kappa = 0 \). However, it will be useful as a building block of our point-particle T-fold.

Consider now the four-dimensional purely gravitational background \( T(\mu, \gamma, m, c) \) with the direct product metric (22) now written in global coordinates \( x, \xi \) of the target space \( \mathbb{R}^2 \times \mathbb{R}^2 \)

\[ ds^2 = 4dx\,d\bar{x} + \gamma^2(x\,dx + \bar{x}\,dx)^2 - \mu^2(x\,dx - \bar{x}\,dx)^2 + 4d\xi\,d\bar{\xi} + c^2(\xi\,d\bar{\xi} + \bar{\xi}\,d\xi)^2 - m^2(\xi\,d\bar{\xi} - \bar{\xi}\,d\xi)^2 \]  

(32)

The dynamics of the neutral point particle in the background (32) is now given by the "doubled" Hamiltonian

\[ H_x = \frac{1}{2}pp + \frac{\mu^2}{8}(p\bar{x} + \bar{p}x)^2 - \frac{\gamma^2}{8}(p\bar{x} - x\bar{p})^2 + \frac{1}{2}\pi\bar{\pi} + \frac{m^2}{8}(\pi\bar{\xi} + \bar{\pi}\xi)^2 - \frac{c^2}{8}(\pi\bar{\xi} - \bar{\pi}\xi)^2. \]  

(33)

and the doubled Darboux symplectic form

\[ \Omega_x = \frac{1}{2}(d\bar{p} \wedge dx + dp \wedge d\bar{x}) + \frac{1}{2}(d\bar{\pi} \wedge d\xi + d\pi \wedge d\bar{\xi}). \]  

(34)

The both quantities \( H_x \) and \( \Omega_x \) are defined on the neutral direct product phase space \( P_x \) parametrized by the global Darboux coordinates \( x, p, \xi, \pi \). The solutions
of the direct product dynamical system \((P_x, H_x, \Omega_x)\) are obviously obtained by doubling Eqs.(30), in particular, we see that they are complete and they remain complete on the following restricted phase space

\[ P_{r;x} = \{(x, p, \xi, \pi) \in P_x; \; p \neq 0, \; \pi \neq 0\}, \tag{35} \]

with the symplectic form (34) and the Hamiltonian (33) (both understood as the restrictions of \(\Omega_x\) and \(H_x\) to \(P_{r;x}\)).

Now we define a diffeomorphism of the restricted phase space \(P_{r;x}\) by the formulas

\[
X = \frac{p}{2|\pi||p|}(\xi\pi + \xi\pi + x\bar{p} - \bar{x}p), \quad P = \left|\frac{p}{\pi}\right|p
\]

\[
\Xi = \frac{\pi}{2|\pi||p|}(\bar{x}p + \bar{x}p + \xi\pi - \bar{\xi}\pi), \quad \Pi = \left|\frac{p}{\pi}\right|\pi.
\]

(36a)

(36b)

Note that the diffeomorphism (36) is involutive, which means that it is equal to its inverse, and it is also symplectic because it holds

\[ \Omega_{r;x} = \frac{1}{2}(d\bar{P} \wedge dX + dP \wedge d\bar{X}) + \frac{1}{2}(d\bar{\Pi} \wedge d\Xi + d\Pi \wedge d\bar{\Xi}). \tag{37} \]

The restricted Hamiltonian in the capital variables now reads

\[ H_{r;x} = \frac{1}{2}\bar{P}^2 + \frac{m^2}{8}(P\bar{X} + \bar{P}X)^2 - \frac{\gamma^2}{8}(P\bar{X} - \bar{P}X)^2 + \frac{1}{2}\bar{\Pi}\bar{\Xi} + \frac{\mu^2}{8}(\bar{\Pi}\bar{\Xi} + \bar{\Pi}\Xi)^2 - \frac{c^2}{8}(\bar{\Pi}\bar{\Xi} - \bar{\Pi}\Xi)^2. \tag{38} \]

We observe that the restricted Hamiltonian \(H_{r;x}\) expressed in the upper case variables has the same form as in the lower case ones (33) except that the parameters \(m\) and \(\mu\) get exchanged! This is of course similar as in the case of the charged particle but now the situation is not quite the same. Indeed, in the neutral case Eq. (36) does not give a symplectomorphism of the whole phase space \(P_x\) but only of the restricted one \(P_{r;x}\) so the interpretation in terms of T-duality is not straightforward.

We could say that in the neutral case the symplectomorphism (36) of the restricted phase space \(P_r\) realizes a sort of local T-duality between the background \(T(\mu, \gamma, m, c)\) (cf. Eq.(32)) and the permuted one \(T(m, \gamma, \mu, c)\), but there is a nicer way to interpret the existence of the symplectomorphism (36) which is inspired by T-fold constructions in string theory [7]. Indeed, we shall interpret (36) as a gluing symplectomorphism defining a point-particle T-fold.

The idea of the point particle T-fold construction is not to restrict the phase \(P_x\) corresponding to the background \(T(\mu, \gamma, m, c)\) in order to relate it to the permuted background \(T(m, \gamma, \mu, c)\) but rather to extend it to a bigger phase space \(P_{e;x}\) which would contain the unrestricted phase spaces of both original and dual backgrounds. The extended phase space \(P_{e;x}\) is thus a manifold the atlas of which has two identical charts \(P_x\) (the lower case one and the upper case one) and the
transition diffeomorphism between those two charts is given by the restricted T-duality map (36). Since each chart is the symplectic manifold and the transition diffeomorphism is the symplectomorphism, the manifold $P_{ex}$ is naturally symplectic, its symplectic form we denote as $\Omega_{ex}$. Of course, the Hamiltonians (33) and (38) define respective dynamical systems on each chart $P_x$. Because the gluing T-duality symplectomorphism (36) takes one Hamiltonian into the other, we see that those two Hamiltonians on the charts define consistently a Hamiltonian $H_{ex}$ on the whole extended phase space $P_{ex}$.

In conclusion, we interpret the extended dynamical system $(P_{ex}, \Omega_{ex}, H_{ex})$ as a non-geometric background for the point particle and we shall refer to it as to the *point-particle T-fold*. We observe, that the T-fold contains at the same time the totality of the dynamics of the neutral point particle in two geometrically different backgrounds $T(\mu, \gamma, m, c)$ and $T(m, \gamma, \mu, c)$.

5 Conclusions and outlook

The principal result of this article is the demonstration of the fact that the phenomenon of the T-duality exists not only in the stringy context but also in the point particle one. The crucial role in the respect is played by the explicit formulas (11) and (36) which realize the point particle T-duality symplectomorphisms respectively for charged and neutral particle moving in the electro-gravitational background (8).

There are several open problems to be addressed in the context of the point-particle T-duality. Among others, it would be nice to find out whether realistic black hole solutions in four space-time dimensions admit point-particle T-duals or to clarify what is a physical relevance of the T-folds in the point-particle physics. However, arguably the most prominent open issue is to work out the quantum status of the point-particle T-duality. Here the situation looks more promising than in string theory, where only the Abelian T-duality is under full control at the quantum level while all other known generalized T-dualities are so far established only classically or were proven to take place up to one or two loops [13, 12, 2, 6, 1].
