GENERALIZED HILBERT-KUNZ FUNCTION OF THE REES ALGEBRA OF
THE FACE RING OF A SIMPLICIAL COMPLEX

ARINDAM BANERJEE, KRITI GOEL, AND J. K. VERMA

ABSTRACT. Let $R$ be the face ring of a simplicial complex of dimension $d - 1$ and $\mathcal{R}(n)$ be the
Rees algebra of the maximal homogeneous ideal $n$ of $R$. We show that the generalized Hilbert-Kunz
function $HK(s) = \ell(\mathcal{R}(n)/(n, nt)^{[s]})$ is given by a polynomial for all large $s$. We calculate it in many
examples and also provide a Macaulay2 code for computing $HK(s)$.

Dedicated to Roger Wiegand and Silvia Wiegand on the occasion of their 150th birthday

1. Introduction

The objective of this paper is to find the generalized Hilbert-Kunz function of the maximal homo-
genous ideal of the Rees algebra of the maximal homogeneous ideal of the face ring of a simplicial
complex. The Hilbert-Kunz functions of the Rees algebra, associated graded ring and the extended
Rees algebra have been studied by K. Eto and K.-i. Yoshida in [3] and by K. Goel, M. Koley and
J. K. Verma in [5].

In order to recall one of the main results of Eto and Yoshida, we set up some notation first. Let
$(R, m)$ be a Noetherian local ring of dimension $d$ and of prime characteristic $p$. Let $q = p^e$ where $e$
is a non-negative integer. The $q^{th}$ Frobenius power of an ideal $I$ is defined to be $I[q] = \{a^q \mid a \in I\}$. Let $I$ be an $m$-primary ideal. The Hilbert-Kunz function of $I$ is the function $HK_I(q) = \ell(R/I[q])$. This
function, for $I = m$, was introduced by E. Kunz in [8] who used it to characterize regular local rings.
The Hilbert-Kunz multiplicity of an $m$-primary ideal $I$ is defined as $e_{HK}(I) = \lim_{q \to \infty} \ell(R/I[q])/q^d$.
It was introduced by P. Monsky in [10]. We refer the reader to an excellent survey paper of C.
Huneke [7] for further details.

Eto and Yoshida calculated the Hilbert-Kunz multiplicity of various blowup algebras of an ideal
under certain conditions. Put $c(d) = (d/2) + d/(d + 1)!$. They proved the following.

Theorem 1.1. Let $(R, m)$ be a Noetherian local ring of prime characteristic $p > 0$ with $d = \dim R \geq
1$. Then for any $m$-primary ideal $I$, we have

$$e_{HK}(\mathcal{R}(I)) \leq c(d) \cdot e(I).$$
Moreover, equality holds if and only if $e_{HK}(R) = e(I)$. When this is the case, $e_{HK}(R) = e(R)$ and $e_{HK}(I) = e(I)$.

It is natural to ask if there is a formula for the Hilbert-Kunz function and the Hilbert-Kunz multiplicity of the maximal homogeneous ideal $(m, I)$ of the Rees algebra $R(I) = \oplus_{n=0}^{\infty} I^n t^n$ where $I$ is an $m$-primary ideal, in terms of invariants of the ideals $m$ and $I$. In this paper we answer this question for the Rees algebra of the maximal homogeneous ideal of the face ring of a simplicial complex. In fact, we find its generalized Hilbert-Kunz function. The generalized Hilbert-Kunz function was introduced by Aldo Conca in [2]. Let $(R, m)$ be a $d$-dimensional Noetherian local (resp. standard graded) ring with maximal (resp. maximal homogeneous) ideal $m$ and $I$ be an $m$-primary (resp. a graded $m$-primary) ideal. Fix a set of generators of $I$, say $I = (a_1, a_2, \ldots, a_g)$. We choose these as homogeneous elements in case $R$ is a graded ring. Define the $s^{th}$ Frobenius power of $I$ to be the ideal $I[s] = (a_1^s, a_2^s, \ldots, a_g^s)$. The generalized Hilbert-Kunz function of $I$ is defined as $HK_I(s) = \ell(R/I[s])$. The generalized Hilbert-Kunz multiplicity is defined as $\lim_{s \to \infty} HK_I(s)/s^d$, whenever the limit exists.

We now describe the contents of the paper. Let $\Delta$ be a simplicial complex of dimension $d - 1$. Let $k$ be any field, $k[\Delta]$ denote the face ring of $\Delta$ and $n$ be its maximal homogeneous ideal. Let $R(n) = \oplus_{n=0}^{\infty} n^n t^n$ be the Rees algebra of $n$. In section 2, we collect some preliminaries required for estimation of the asymptotic reduction number in terms of the $a$-invariants of local cohomology modules and Hilbert-Samuel polynomial of the maximal homogeneous ideal of the face ring of a simplicial complex. Section 3 is devoted to the computation of the generalized Hilbert-Kunz function $HK_{(n, nt)}(s)$, where $(n, nt)$ is the maximal homogeneous ideal of the Rees algebra $R(n)$. We also estimate an upper bound on the postulation number of $HK_{(n, nt)}(s)$ in terms of $a$-invariants of the local cohomology modules. This enables us to explicitly calculate the generalized Hilbert-Kunz function for the Rees algebra in several examples such as the edge ideal of a complete bipartite graph, the real projective plane and a few other examples of simplicial complexes. We have implemented the formula for the Hilbert-Kunz function in an algorithm written in the language of Macaulay2.

2. Preliminaries

In this section we gather some results which we shall use in the later sections. Let $R$ be a ring and $I$ be an $R$ ideal. An ideal $J \subseteq I$ is called a reduction of $I$ if $JI^n = I^{n+1}$, for all large $n$. A minimal reduction of $I$ is a reduction of $I$ minimal with respect to inclusion. For a minimal reduction $J$ of $I$, we set $r_J(I) = \min\{n \mid I^{n+1} = JI^m$ for all $m \geq n\}$. The reduction number of $I$ is defined as

$$r(I) = \min\{r_J(I) \mid J$ is a minimal reduction of $I\}.$$ 

We shall use the following results to estimate the reduction number of powers of an ideal.
Theorem 2.1 ([9, Corollary 2.21]). Let \((R, m)\) be a \(d\)-dimensional Cohen-Macaulay local ring with infinite residue field and \(I\) be an \(m\)-primary ideal such that \(\text{grade}(G(I)_+) \geq d - 1\). Then for \(k \geq 1\),
\[
r(I^k) = \left\lfloor \frac{n(I)}{k} \right\rfloor + d,
\]
where \(n(I)\) denotes the postulation number of \(I\).

Theorem 2.2 ([4, Theorem 2.1]). Let \((R, m)\) be a Noetherian local ring and let \(I \subseteq m\) be an \(R\)-ideal. Then \(r_J(I^n)\) is independent of \(J\) and stable if \(n\) is large. In particular, for all \(n > \max\{|a_i(G(I))|: a_i(G(I)) \neq -\infty\}\), we get
\[
r_J(I^n) = \begin{cases} s & \text{if } a_s(G(I)) \geq 0, \\ s - 1 & \text{if } a_s(G(I)) < 0, \end{cases}
\]
where \(J\) is any minimal reduction of \(I^n\) and \(s\) is the analytic spread of \(I\).

Let \(S\) be a \(d\)-dimensional Cohen-Macaulay local ring and let \(I\) be a parameter ideal. Fix \(s \in \mathbb{N}\). For a fixed set of generators of \(I\), define functions
\[
F(n) := H_I(I^{[s]}, n) = \ell_S \left( \frac{I^{[s]}}{I^{[s]}I^n} \right) \quad \text{and} \quad H(n) := H_I(S, n) = \ell_S \left( \frac{S}{I^n} \right) = e(I) \binom{n + d - 1}{d}
\]
for all \(n\). Note that if \(S\) is 1-dimensional, then \(F(n) = H(n)\) for all \(n\). In [5], the authors prove that the function \(F(n)\) is a piecewise polynomial in \(n\).

Theorem 2.3 ([5, Theorem 3.2]). Let \(S\) be a \(d\)-dimensional Cohen-Macaulay local ring and \(I\) be a parameter ideal. Let \(d \geq 2\). For a fixed \(s \in \mathbb{N}\),
\[
F(n) = \begin{cases} d \ H(n) & \text{if } 1 \leq n \leq s, \\ \sum_{i=1}^{d-1} (-1)^{i+1} \binom{d}{i} H(n - (i - 1)s) & \text{if } s + 1 \leq n \leq (d - 1)s - 1, \\ H(n + s) - s^d e(I) & \text{if } n \geq (d - 1)s. \end{cases}
\]

Let \(\Delta\) be a \((d - 1)\)-dimensional simplicial complex on \(n\) vertices and \(k\) be a field. Let \(R = k[\Delta]\) be the corresponding Stanley-Reisner ring and \(n\) be its unique maximal homogeneous ideal. Let \(h(\Delta) = (h_0, h_1, \ldots, h_d)\) and \(f(\Delta) = (f_{-1}, f_0, \ldots, f_{d-1})\) denote the \(h\)-vector and \(f\)-vector of \(\Delta\) respectively. We use the following formula for the Hilbert-Samuel polynomial of \(n\) in the main result.

Theorem 2.4 ([6, Theorem 6.2]). Set \(h(\lambda) = h_0 + h_1 \lambda + \cdots + h_d \lambda^d\). Let \(h^{(i)}(\lambda)\) denote the \(i\)-th derivative of \(h(\lambda)\) with respect to \(\lambda\). Then for all \(n \geq 1\),
\[
\ell \left( \frac{R}{n} \right) = \sum_{i=0}^{d} (-1)^i \frac{h^{(i)}(1)}{i!} \binom{n + d - i - 1}{d - i}.
\]
Let $S = k[x_1, \ldots, x_r]$ be a polynomial ring in $r$ variables over a field $k$ and let $m = (x_1, \ldots, x_r)$ denote the maximal homogeneous ideal of $S$. Let $P_j$, for $j = 1, \ldots, \alpha$ and $\alpha \geq 2$, be distinct $S$-ideals generated by subsets of $\{x_1, \ldots, x_r\}$. Let $I = \cap_{j=1}^\alpha P_j$ and $R = S/I$. Let $n = m/I$ denote the maximal homogeneous ideal of $R$.

In this section, we find the generalized Hilbert-Kunz function of the maximal homogeneous ideal $(n, nt)$ of the Rees algebra $R(n)$ of $R$. We begin by proving that for $s, n \in \mathbb{N}$, $\ell_S(S/I + m^s m^n)$ is a piecewise polynomial in $s$ and $n$. First we prove the following result which is a consequence of Theorem 2.3.

**Corollary 3.1.** Let $S = k[x_1, \ldots, x_d]$ be a polynomial ring in $d$ variables over a field $k$. Let $m = (x_1, \ldots, x_d)$ be its maximal homogeneous ideal. Let $s, n \in \mathbb{N}$.

1. If $d = 1$, then $\ell \left( \frac{S}{m^s m^n} \right) = s + n$.
2. If $d = 2$, then
   $$\ell \left( \frac{S}{m^s m^n} \right) = \begin{cases} s^2 + n^2 + n & \text{if } 1 \leq n \leq s, \\ (n + s + 1) & \text{if } n \geq s. \end{cases}$$
3. If $d \geq 3$, then
   $$\ell \left( \frac{S}{m^s m^n} \right) = \begin{cases} s^d + d \binom{n + d - 1}{d} & \text{if } 1 \leq n \leq s, \\ s^d + \sum_{i=1}^{d-1} (-1)^{i+1} \binom{d}{i} \binom{n - (i - 1)s + d - 1}{d} & \text{if } s + 1 \leq n \leq (d - 1)s - 1, \\ (n + s + d - 1) & \text{if } n \geq (d - 1)s. \end{cases}$$

**Proof.** Let $s, n \in \mathbb{N}$. If $d = 1$, then $S = k[x]$ and $m = (x)$ implying that
$$\ell \left( \frac{S}{m^s m^n} \right) = \ell \left( \frac{k[x]}{(x^{s+n})} \right) = s + n.$$ Let $d \geq 2$. Since
$$\ell \left( \frac{S}{m^s m^n} \right) = \ell \left( \frac{S}{m^s} \right) + \ell \left( \frac{m^s}{m^s m^n} \right)$$ and $\ell(S/m^s) = s^d$, the result follows from Theorem 2.3. 

Let $T = \oplus_{n \geq 0} T_n$ be a Noetherian graded ring, where $T_0$ is an Artinian ring. Let $M = \oplus_{n \geq 0} M_n$ be a finitely generated graded $T$-module. Then $\ell_{T_0}(M_n) < \infty$. The Hilbert series $H(M, \lambda)$ of $M$ is defined by $H(M, \lambda) = \sum_{n \geq 0} \ell_{T_0}(M_n) \lambda^n$. 

Theorem 3.2. Let $T$ be a standard graded Artinian ring and let $I_1, \ldots, I_\alpha$, for $\alpha \geq 2$, be homogeneous $T$-ideals. Let $I = \bigcap_{i=1}^\alpha I_i$. Then

$$H \left( \frac{T}{I}, \lambda \right) = \sum_{i=1}^\alpha H \left( \frac{T}{I_i}, \lambda \right) - \sum_{i,j=1 \atop i < j}^\alpha H \left( \frac{T}{I_i + I_j}, \lambda \right) \cdots + (-1)^{\alpha-1} H \left( \frac{T}{\sum_{i=1}^\alpha I_i}, \lambda \right).$$

Proof. Apply induction on $\alpha$. Let $\alpha = 2$. Consider the following short exact sequence

$$0 \rightarrow \frac{T}{I_1 \cap I_2} \rightarrow \frac{T}{I_1} \bigoplus \frac{T}{I_2} \rightarrow \frac{T}{I_1 + I_2} \rightarrow 0.$$

Then

$$H \left( \frac{T}{I}, \lambda \right) = H \left( \frac{T}{I_1 \cap I_2}, \lambda \right) = H \left( \frac{T}{I_1}, \lambda \right) + H \left( \frac{T}{I_2}, \lambda \right) - H \left( \frac{T}{I_1 + I_2}, \lambda \right).$$

Let $\alpha > 2$ and consider the short exact sequence

$$0 \rightarrow \frac{T}{\bigcap_{i=1}^\alpha I_i} \rightarrow \frac{T}{\bigcap_{i=1}^{\alpha-1} I_i} \bigoplus \frac{T}{I_\alpha} \rightarrow \frac{T}{\bigcap_{i=1}^\alpha I_i + I_\alpha} \rightarrow 0.$$

Using induction hypothesis, it follows that

$$H \left( \frac{T}{\bigcap_{i=1}^\alpha I_i}, \lambda \right) = H \left( \frac{T}{\bigcap_{i=1}^{\alpha-1} I_i}, \lambda \right) + H \left( \frac{T}{I_\alpha}, \lambda \right) - H \left( \frac{T}{\bigcap_{i=1}^{\alpha-1} I_i + I_\alpha}, \lambda \right)$$

$$= \sum_{i=1}^{\alpha-1} H \left( \frac{T}{I_i}, \lambda \right) - \sum_{i,j=1 \atop i < j}^{\alpha-1} H \left( \frac{T}{I_i + I_j}, \lambda \right) \cdots + (-1)^{\alpha-2} H \left( \frac{T}{\sum_{i=1}^{\alpha-1} I_i}, \lambda \right)$$

$$+ H \left( \frac{T}{I_\alpha}, \lambda \right) - \sum_{i=1}^{\alpha-1} H \left( \frac{T}{I_i + I_\alpha}, \lambda \right) + \sum_{i,j=1 \atop i < j}^{\alpha-1} H \left( \frac{T}{I_i + I_j + I_\alpha}, \lambda \right) \cdots$$

$$+ (-1)^{\alpha-1} H \left( \frac{T}{\sum_{i=1}^{\alpha-1} I_i + I_\alpha}, \lambda \right).$$

Rearranging the terms gives the required result. \qed

Corollary 3.3. Let $S = k[x_1, \ldots, x_r]$ be a polynomial ring in $r$ variables over a field $k$ and let $m = (x_1, \ldots, x_r)$ be the maximal homogeneous ideal of $S$. Let $P_1, \ldots, P_\alpha$, for $\alpha \geq 2$, be distinct $S$-ideals generated by subsets of $\{x_1, \ldots, x_r\}$. Let $I = \bigcap_{i=1}^\alpha P_i$. Then for $s, n \in \mathbb{N},$

$$\ell \left( \frac{S}{I + m^s} \right) = \sum_{i=1}^\alpha \ell \left( \frac{S}{P_i + m^s} \right) - \sum_{1 \leq i < j \leq \alpha} \ell \left( \frac{S}{P_i + P_j + m^s} \right) + \cdots$$

$$+ (-1)^{\alpha-1} \ell \left( \frac{S}{\sum_{i=1}^\alpha P_i + m^s} \right).$$

In particular, $\ell \left( \frac{S}{I + m^s} \right)$ is a piecewise polynomial in $s$ and $n$. (3.1)
Proof. Since $S/\mathfrak{m}^n$ is a standard graded Artinian ring, using Theorem 3.2 it follows that

$$H\left(\frac{S}{I + \mathfrak{m}^n}, \lambda\right) = \sum_{i=1}^{\alpha} H\left(\frac{S}{P_i + \mathfrak{m}^n}, \lambda\right) - \sum_{i<j}^{\alpha} H\left(\frac{S}{P_i + P_j + \mathfrak{m}^n}, \lambda\right) + \cdots + (-1)^{\alpha-1} H\left(\frac{S}{\sum_{i=1}^{\alpha} P_i + \mathfrak{m}^n}, \lambda\right).$$

(3.2)

The modules involved on the right side of (3.2) are finite length $S$-modules. Put $\lambda = 1$ in (3.2) to get (3.1). Observe that $S/(P_{i_1} + \cdots + P_{i_j})$, for $i_1, \ldots, i_j \in \{1, \ldots, \alpha\}$, is isomorphic to a polynomial ring. Since image of $\mathfrak{m}$ in $S/(P_{i_1} + \cdots + P_{i_j})$ is a parameter ideal for all $i_1, \ldots, i_j \in \{1, \ldots, \alpha\}$, using Corollary 3.1 we obtain the required result. □

The following result is a generalization of A. Conca’s result ([2, Remark 2.2]).

**Theorem 3.4.** For $s \geq 1$, the generalized Hilbert-Kunz function of $R = k[\Delta]$ is given by the equation

$$\ell \left( \frac{R}{n^s} \right) = \sum_{i=0}^{d} f_{i-1}(s-1)^i.$$

Proof. Observe that $\ell(R/n^s) = |V|$, where

$$V = \{a = (a_1, \ldots, a_r) \in \mathbb{N}^r \mid 0 \leq a_i \leq s - 1 \text{ and } \text{Supp}(a) \in \Delta\}.$$

Therefore, for $s \geq 1$,

$$\ell \left( \frac{R}{n^s} \right) = \sum_{F \in \Delta} |\{a \in V \mid \text{Supp}(a) \in F\}| = \sum_{F \in \Delta} (s-1)^{|F|} = \sum_{i=0}^{d} f_{i-1}(s-1)^i.$$

We are now ready to prove the main result of the section. We first consider the general case.

### 3.1. The generalized Hilbert-Kunz function of $(n, nt)$.

**Theorem 3.5.** Let $S = k[x_1, \ldots, x_r]$ be a polynomial ring in $r$ variables over a field $k$ and let $\mathfrak{m}$ be the maximal homogeneous ideal of $S$. Let $P_1, \ldots, P_\alpha$, for $\alpha \geq 2$, be distinct $S$-ideals generated by subsets of $\{x_1, \ldots, x_r\}$. Let $I = \cap_{i=1}^{\alpha} P_i$ and $R = S/I$. Suppose $n = \mathfrak{m}/I$ denotes the maximal homogeneous ideal of $R$ and dim$(R) = d$. Set $\delta = \max\{|a_i(R)| : a_i(R) \neq -\infty\}$. Then for $s > \delta$,

$$\ell \left( \frac{R(n)}{(n, nt)[s]} \right)$$

is a polynomial in $s$. 

Proof. Since $R$ is a standard graded ring, it follows that $R \simeq G(n)$. Let $s > \delta$. Using Theorem 2.2, it follows that

$$r(n^s) = \begin{cases} 
  d - 1 & \text{if } a_d(R) < 0, \\
  d & \text{if } a_d(R) = 0.
\end{cases}$$

In other words, $r(n^s) = d - j$, where $j$ is either 0 or 1 as per the above observation. As $n^{[s]}$ is a minimal reduction of $n^s$, we get, $n^{[s]}n^{(d-j)s} = n^{(d-j+1)s}$. In other words, $n^{[s]}n^{n-s} = n^n$, for all $n \geq (d-j+1)s$. This implies that

$$(n, nt)[s] = (n^{[s]}, n^{[s]}t^s) = \left( \bigoplus_{n=0}^{s-1} n^{[s]}n^t n^n \right) + \left( \bigoplus_{n=s}^{(d-j+1)s-1} n^{[s]}n^{n-s}t^n \right) = \left( \bigoplus_{n=0}^{s-1} n^{[s]}n^t n^n \right) + \left( \bigoplus_{n=s}^{(d-j+1)s-1} n^{[s]}n^{n-s}t^n \right) + \left( \bigoplus_{n \geq (d-j+1)s} n^n t^n \right).$$

Therefore, for $s > \delta$,

$$\ell \left( \frac{R(n)}{(n, nt)[s]} \right) = \sum_{n=0}^{s-1} \ell \left( \frac{n^n}{n^{[s]}n^n} \right) + \sum_{n=s}^{(d-j+1)s-1} \ell \left( \frac{n^n}{n^{[s]}n^{n-s}} \right) = \sum_{n=0}^{s-1} \ell \left( \frac{R}{n^{[s]}n^n} \right) + \sum_{n=s}^{(d-j+1)s-1} \ell \left( \frac{R}{n^{[s]}n^{n-s}} \right) - \sum_{n=0}^{(d-j+1)s-1} \ell \left( \frac{R}{n^n} \right) = \sum_{n=1}^{s-1} \ell \left( \frac{S}{I + m[\ell]m^n} \right) + \sum_{n=s}^{(d-j+1)s-1} \ell \left( \frac{S}{I + m[\ell]m^n} \right) - \sum_{n=1}^{(d-j+1)s-1} \ell \left( \frac{R}{n^n} \right) + 2 \ell \left( \frac{R}{n^n} \right) = 2 \sum_{n=1}^{s-1} \ell \left( \frac{S}{I + m[\ell]m^n} \right) + \sum_{n=s}^{(d-j+1)s-1} \ell \left( \frac{S}{I + m[\ell]m^n} \right) - \sum_{n=1}^{(d-j+1)s-1} \ell \left( \frac{R}{n^n} \right) + 2 \ell \left( \frac{R}{n^n} \right).$$

The result now follows from Corollary 3.3, Theorem 2.4 and Theorem 3.4. 

\[ \square \]

3.2. The generalized Hilbert-Kunz function of $(n, nt)$ for Cohen-Macaulay $k[\Delta]$.

**Theorem 3.6.** Let $S = k[x_1, \ldots, x_r]$ be a polynomial ring in $r$ variables over a field $k$ and let $m$ be the maximal homogeneous ideal of $S$. Let $P_1, \ldots, P_\alpha$, for $\alpha \geq 2$, be distinct $S$-ideals generated by subsets of $\{x_1, \ldots, x_r\}$. Let $I = \cap_{i=1}^\alpha P_i$ and $R = S/I$. Suppose $n = m/I$ denotes the maximal homogeneous ideal of $R$ and $\dim(R) = d$. Suppose that $R$ is Cohen-Macaulay. Then

$$\ell \left( \frac{R(n)}{(n, nt)[s]} \right)$$

is given by a polynomial for $s \geq 1$.

**Proof.** Since $R$ is a standard graded ring, it follows that $R \simeq G(n)$. Let $h(\Delta) = (h_0, \ldots, h_d)$ denote the $h$-vector of $R$. Note that $-d < n(n) \leq 0$. If $n(n) = -d$, then $h_0 = 1$ and $h_i = 0$ for all $i \neq 0$,
implying that $0 = h_1 = r - d$. It follows that $I$ is a height zero ideal, which is not true. Hence, $-d < n(n) \leq 0$.

Suppose $n(n) = 0$. Using Theorem 2.1, it follows that $r(I^s) = d$, for all $s \geq 1$. Using the same arguments as in the proof of Theorem 3.5, we are done. □

In this section, we illustrate the above results using some examples.

In other words, $r(I^s) = d - j$, where $j \in \{1, k_1, k_1 + 1\}$ as per the above observation. Using the same arguments as in the proof of Theorem 3.5, we are done.

4. Examples

In this section, we illustrate the above results using some examples.

Example 4.1. Let $\Delta$ be the simplicial complex

$x_1 \quad x_2 \quad x_3 \quad x_4$

Then $R = k[x_1, x_2, x_3, x_4]/((x_1, x_2) \cap (x_3, x_4))$ is the face ring of $\Delta$. Observe that $R$ is a 2-dimensional ring with $f$-vector $f(\Delta) = (1, 4, 2)$ and $h$-vector $h(\Delta) = (1, 2, -1)$. Set $S = k[x_1, x_2, x_3, x_4]$, $P_1 = (x_1, x_2)$, $P_2 = (x_3, x_4)$. Since depth($R$) = 1, it follows that $a_0(R) = -\infty$. In order to find $a_1(R)$ and $a_2(R)$, we consider the following short exact sequence.

$$0 \rightarrow \frac{S}{P_1 \cap P_2} \rightarrow \frac{S}{P_1} \bigoplus \frac{S}{P_2} \rightarrow \frac{S}{P_1 + P_2} \rightarrow 0$$

Using the corresponding long exact sequence of local cohomology modules, it follows that

$$H^1_n(R) \simeq H^0_m(S/(P_1 + P_2)) \text{ and } H^2_n(R) \simeq H^2_{(x_3, x_4)}(k[x_3, x_4]) \oplus H^2_{(x_1, x_2)}(k[x_1, x_2]).$$

This implies that $a_1(R) = 0$ and $a_2(R) = -2$. Hence, $\delta = \max\{|a_i(R)|: a_i(R) \neq -\infty\} = 2$. Since $a_2(R) < 0$, using Theorem 3.5 it follows that for all $s > 2$,

$$\ell \left( \frac{R(n)}{(n, nt)[s]} \right) = 2 \sum_{n=1}^{s-1} \ell \left( \frac{S}{I + m^s m^n} \right) - 2 \sum_{n=1}^{s-1} \ell \left( \frac{R}{n^n} \right) + 2 \ell \left( \frac{R}{n^s} \right).$$
From Corollary 3.3, Theorem 2.4 and Theorem 3.4, we obtain

\[
\ell \left( \frac{\mathcal{R}(n)}{(n, nt)^{[s]}} \right) = 2 \sum_{n=1}^{2s-1} \left[ \ell \left( \frac{S}{P_1 + m^s \cdot m^n} \right) + \ell \left( \frac{S}{P_2 + m^s \cdot m^n} \right) - \ell \left( \frac{S}{P_1 + P_2 + m^s \cdot m^n} \right) \right] - \sum_{i=1}^{2s-1} \left[ \sum_{i=0}^{2} (-1)^i \frac{H^{(i)}(1)}{i!} \left( \frac{n + 1 - i}{2 - i} \right) + 2 \sum_{i=0}^{2} f_{i-1}(s - 1)^i \right].
\]

Substituting the values and using Corollary 3.1, we get

\[
\ell \left( \frac{\mathcal{R}(n)}{(n, nt)^{[s]}} \right) = 2 \sum_{n=1}^{2s-1} \left[ 2(s^2 + n^2 + \frac{1}{2}) + \frac{1}{2} \right] - \sum_{n=1}^{2s-1} \left[ 2 \left( \frac{n + 1}{2} \right) + \frac{1}{2} \right] + 2 \left[ 1 + 4(s - 1) + 2(s - 1)^2 \right].
\]

Simplifying the above expression, we obtain that for all \( s > 2, \)

\[
\ell \left( \frac{\mathcal{R}(n)}{(n, nt)^{[s]}} \right) = \frac{8}{3} s^3 - \frac{2}{3} s - 1
\]

\[
= 16 \left( \frac{s + 2}{3} \right) - 16 \left( \frac{s + 1}{2} \right) + 2s - 1.
\]

**Example 4.2.** Let \( \Delta \) be the simplicial complex

![Diagram of a simplicial complex](image)

Then \( R = k[x_1, x_2, x_3, x_4]/((x_1) \cap (x_3, x_4)) \) is the face ring of \( \Delta \). Observe that \( R \) is a 3-dimensional ring with \( f \)-vector \( f(\Delta) = (1, 4, 4, 1) \) and \( h \)-vector \( h(\Delta) = (1, 1, -1, 0) \). Set \( S = k[x_1, x_2, x_3, x_4], \)
\( P_1 = (x_3, x_4), \) \( P_2 = (x_1). \) Since \( \text{depth}(R) = 2 \), it follows that \( a_0(R) = a_1(R) = -\infty \). In order to find \( a_2(R) \) and \( a_3(R) \), we consider the following short exact sequence.

\[
0 \rightarrow S \rightarrow \frac{S}{P_1 \cap P_2} \rightarrow \frac{S}{P_1} \bigoplus \frac{S}{P_2} \rightarrow \frac{S}{P_1 + P_2} \rightarrow 0
\]

Using the corresponding long exact sequence of local cohomology modules, we get

\[
H^3_n(R) \simeq H^3_{(x_2, x_3, x_4)}(k[x_2, x_3, x_4]) \text{ and } 0 \rightarrow H^1_{(x_2)}(k[x_2]) \rightarrow H^2_n(R) \rightarrow H^2_{(x_1, x_2)}(k[x_1, x_2]) \rightarrow 0.
\]

This implies that \( a_2(R) = -1 \) and \( a_3(R) = -3. \) Hence, \( \delta = \max\{|a_i(R)| : a_i(R) \neq -\infty\} = 3. \) Since \( a_3(R) < 0, \) using Theorem 3.5 it follows that for all \( s > 3, \)

\[
\ell \left( \frac{\mathcal{R}(n)}{(n, nt)^{[s]}} \right) = 2 \sum_{n=1}^{s-1} \ell \left( \frac{S}{I + m^s \cdot m^n} \right) + \sum_{n=s}^{2s-1} \ell \left( \frac{S}{I + m^s \cdot m^n} \right) - \sum_{n=1}^{3s-1} \ell \left( \frac{R}{m^n} \right) + 2 \ell \left( \frac{R}{n^s} \right).
\]
From Corollary 3.3, Theorem 2.4 and Theorem 3.4, we obtain
\[
\ell \left( \frac{\mathcal{R}(n)}{(n, n^n)^{[s]}} \right) = 2 \sum_{n=1}^{s-1} \left[ \ell \left( \frac{S}{P_1 + m^n} \right) + \ell \left( \frac{S}{P_2 + m^n} \right) - \ell \left( \frac{S}{P_1 + P_2 + m^n} \right) \right] + 2s-1 \left[ \ell \left( \frac{S}{P_1 + m^n} \right) + \ell \left( \frac{S}{P_2 + m^n} \right) - \ell \left( \frac{S}{P_1 + P_2 + m^n} \right) \right] - 3s-1 \sum_{i=0}^{3} \left[ \sum_{i=0}^{n} f(i) \left( \frac{n + d - i - 1}{d - i} \right) \right] + 2 \sum_{i=0}^{3} f_{i-1}(s-1)^i.
\]

Substituting the values and using Corollary 3.1, we get
\[
\ell \left( \frac{\mathcal{R}(n)}{(n, n^n)^{[s]}} \right) = 2 \sum_{n=1}^{s-1} \left[ (s^2 + n^2 + n) + s^3 + 3 \left( \frac{n+2}{3} \right) - (s+n) \right] + 2s-1 \left[ (n+s+1) + s^3 + 3 \left( \frac{n+2}{3} \right) - 3 \left( \frac{n-s+2}{3} \right) - (s+n) \right] - 3s-1 \left[ \left( \frac{n+2}{3} \right) + \left( \frac{n+1}{2} \right) - n \right] + 2 \left[ 1 + 4(s-1) + 4(s-1)^2 + (s-1)^3 \right].
\]

Simplifying the above expression, we obtain that for all \( s > 3, \)
\[
\ell \left( \frac{\mathcal{R}(n)}{(n, n^n)^{[s]}} \right) = 13 \frac{s^4}{8} + 13 \frac{s^3}{12} - 9 \frac{s^2}{8} - 7 \frac{1}{12} s - 39 \left( \frac{s+3}{4} \right) - 52 \left( \frac{s+2}{3} \right) + 14 \left( \frac{s+1}{2} \right).
\]

**Example 4.3.** Let \( \Delta \) be the simplicial complex
\[
\begin{tikzpicture}
\node (x1) at (0,0) [circle,fill,inner sep=2pt] {}; \node (x2) at (1,0) [circle,fill,inner sep=2pt] {}; \node (x3) at (2,1) [circle,fill,inner sep=2pt] {}; \node (x4) at (1,2) [circle,fill,inner sep=2pt] {};
\draw (x1) -- (x2) -- (x3) -- (x1);
\end{tikzpicture}
\]

Then \( R = k[x_1, x_2, x_3, x_4]/((x_3, x_4) \cap (x_1, x_3) \cap (x_1, x_4) \cap (x_1, x_2)) \) is the face ring of \( \Delta. \) Observe that \( R \) is a 2-dimensional Cohen-Macaulay ring with \( f \)-vector \( f(\Delta) = (1, 4, 4) \) and \( h \)-vector \( h(\Delta) = (1, 2, 1). \) This implies that \( n(n) = 0. \) Using Theorem 3.6, it follows that for \( s \geq 1, \)
\[
\ell \left( \frac{\mathcal{R}(n)}{(n, n^n)^{[s]}} \right) = 2 \sum_{n=1}^{s-1} \ell \left( \frac{S}{I + m^n} \right) + \sum_{n=s}^{2s-1} \ell \left( \frac{S}{I + m^n} \right) - \sum_{n=1}^{3s-1} \ell \left( \frac{R}{n^n} \right) + 2 \ell \left( \frac{R}{n^s} \right).
\]

Substituting, we get
\[
\ell \left( \frac{\mathcal{R}(n)}{(n, n^n)^{[s]}} \right) = 2 \sum_{n=1}^{s-1} \left[ 4(s^2 + n^2 + n) - 4(s+n) + 1 \right] + \sum_{n=s}^{2s-1} \left[ 4 \left( \frac{n+s+1}{2} \right) - 4(s+n) + 1 \right] - \sum_{n=1}^{3s-1} \left[ 4 \left( \frac{n+1}{2} \right) - 4n + 1 \right] + 2 \left[ 1 + 4(s-1) + 4(s-1)^2 \right].
\]
Simplifying the above expression, we obtain that for all $s \geq 1$,

$$
\ell \left( \frac{R(n)}{(n, nt)[s]} \right) = \frac{16}{3} s^3 - 4s^2 - \frac{4}{3} s + 1
= 32 \left( \frac{s + 2}{3} \right) - 40 \left( \frac{s + 1}{2} \right) + 8s + 1.
$$

**Example 4.4.** Let $\Delta$ be a 1-dimensional simplicial complex on $r$ vertices, for some $r \geq 3$ :

```
\begin{center}
  \begin{tikzpicture}
    \node (x1) at (0,0) {$x_1$};
    \node (x2) at (1,0) {$x_2$};
    \node (x3) at (2,0) {$x_3$};
    \node (xn) at (2,0) {$\cdots$};
    \node (xr) at (4,0) {$x_{r-1}$};
    \node (xr) at (4,0) {$x_r$};
  \end{tikzpicture}
\end{center}
```

For $i = 1, \ldots, r - 1$, set $P_i = (\{x_1, \ldots, x_r\} \setminus \{x_i, x_{i+1}\})$. Then $R = k[x_1, \ldots, x_r]/ \cap_{i=1}^{r-1} P_i$ is the face ring of $\Delta$. It is a two-dimensional Cohen-Macaulay ring with $f$-vector $f(\Delta) = (1, r, r - 1)$ and $h$-vector $h(\Delta) = (1, r - 2, 0)$. Since the $a$-invariant $a_2(R) = -1$, using Theorem 3.6, it follows that for $s \geq 1$,

$$
\ell \left( \frac{R(n)}{(n, nt)[s]} \right)
= 2 \sum_{n=1}^{s-1} \ell \left( \frac{S}{I + m^s m^n} \right) - 2 \sum_{n=1}^{s-1} \ell \left( \frac{R}{n^n} \right) + 2 \ell \left( \frac{R}{n^s} \right)
= 2 \sum_{n=1}^{s-1} \sum_{i=1}^{r-1} \ell \left( \frac{S}{P_i + m^s m^n} \right) - 2 \sum_{i,j=1}^{r-1} \ell \left( \frac{S}{P_i + P_j + m^s m^n} \right) + \cdots + (-1)^{r-2} \ell \left( \frac{S}{\sum_{i=1}^{r-1} P_i + m^s m^n} \right)
- \sum_{n=1}^{s-1} \sum_{i=0}^{2s-2} (-1)^i \frac{h(i)(1)}{i!} \left( \frac{n + 1 - i}{2} \right) + 2 \sum_{i=0}^{2s-2} f_{i-1}(s - 1)^i.
$$

Observe that in this case, using Corollary 3.1, it follows that $\ell(S/(P_i + m^s m^n)) = s^2 + n^2 + n$, for all $1 \leq n \leq s - 1$ and for all $i = 1, \ldots, r - 1$. For $1 \leq i < j \leq r - 1$, if $\{x_i, x_{i+1}\} \cap \{x_j, x_{j+1}\} \neq \emptyset$, then $S/(P_i + P_j) \simeq k[x]$ and there are $r - 2$ such instances. Otherwise, $S/(P_i + P_j) \simeq k$. It is also easy to observe that $S/(P_{i_1} + \cdots + P_{i_u}) \simeq k$, for all $u \geq 3$ and $i_1, \ldots, i_u \in \{1, \ldots, r - 1\}$. Therefore,

$$
\ell \left( \frac{R(n)}{(n, nt)[s]} \right)
= 2 \sum_{n=1}^{s-1} \left[ (r - 1)(s^2 + n^2 + n) - \left[ (r - 2)(s + n) + \left( \frac{r - 1}{2} \right) - (r - 2) \right] + \left( \frac{r - 1}{3} \right) + \cdots + (-1)^{r-2} \right]
- \sum_{n=1}^{s-1} \left[ (r - 1) \left( \frac{n + 1}{2} \right) - (r - 2) n \right] + 2 \left[ 1 + r(s - 1) + (r - 1)(s - 1)^2 \right].
$$
Since, \( \sum_{i=2}^{r-1} (-1)^i \binom{r-1}{i} = r - 2 \), simplifying the above expression we get

\[
\ell \left( \frac{\mathcal{R}(n)}{(n,nt)[s]} \right) = \frac{4}{3}(r-1)s^3 - (r-2)s^2 - \frac{(r-1)}{3}s
\]

\[
= 8(r-1) \left( \frac{s+2}{3} \right) - 2(5r-6) \left( \frac{s+1}{2} \right) + (2r-3)s.
\]

We need some terminologies for the next example.

**Definition 4.5.** Let \( G \) be a finite simple graph with vertices \( V = V(G) = \{x_1, \ldots, x_n\} \) and the edges \( E = E(G) \). The edge ideal of \( I(G) \) of \( G \) is defined to be the ideal in \( K[x_1, \ldots, x_n] \) generated by the square free quadratic monomials representing the edges of \( G \), i.e.,

\[
I(G) = \langle x_i x_j \mid x_i x_j \in E \rangle.
\]

A vertex cover of a graph is a set of vertices such that every edge has at least one vertex belonging to that set. A minimal vertex cover is a vertex cover such that none of its subsets is a vertex cover. For any graph \( G \) with the set of all minimal vertex covers \( C \), the edge ideal \( I(G) \) has the primary decomposition:

\[
I(G) = \bigcap_{\{x_{i_1}, \ldots, x_{i_u}\} \in C} (x_{i_1}, \ldots, x_{i_u}).
\]

For example, when \( G \) is a five cycle, the primary decomposition of the edge ideal

\[
I(G) = (x_1 x_2, x_2 x_3, x_3 x_4, x_4 x_5, x_5 x_1)
\]

\[
= (x_1, x_2, x_4) \cap (x_1, x_3, x_5) \cap (x_1, x_3, x_4) \cap (x_2, x_3, x_5) \cap (x_2, x_4, x_5).
\]

**Example 4.6 (Complete Bipartite Graphs).** A complete bipartite graph \( K_{\alpha,\beta} \) is a graph whose set of vertices is decomposed into two disjoint sets such that no two vertices within the same set are adjacent and that every pair of vertices in the two sets are adjacent.

![Figure 1. K_{\alpha,\beta}](image)

Let \( S = k[x_1, \ldots, x_\alpha, y_1, \ldots, y_\beta] \), where \( 3 \leq \alpha \leq \beta \). The edge ideal of \( K_{\alpha,\beta} \) is the ideal \( I = (x_i y_j \mid 1 \leq i \leq \alpha, 1 \leq j \leq \beta) \). Observe that \( R = S/I \) is a \( \beta \)-dimensional ring. Let \( P_1 = (x_1, \ldots, x_\alpha) \), \( P_2 = (y_1, \ldots, y_\beta) \). Then \( I = P_1 \cap P_2 \). Note that \( I \) is the Stanley-Reisner ideal of the union of an \( \alpha \)-simplex and a \( \beta \)-simplex.
In order to find the $\alpha$-invariants we consider the following short exact sequence.

$$0 \rightarrow \frac{S}{P_1 \cap P_2} \rightarrow \frac{S}{P_1} \bigoplus \frac{S}{P_2} \rightarrow \frac{S}{P_1 + P_2} \rightarrow 0$$

Using the corresponding long exact sequence of local cohomology modules, it follows that

$$H^1_n(R) \simeq H^0_m\left(\frac{S}{P_1 + P_2}\right), \ H^\alpha_n(R) \simeq H^\alpha_{(x_1, \ldots, x_\alpha)}(k[x_1, \ldots, x_\alpha]) \text{ and } H^\beta_n(R) \simeq H^\beta_{(y_1, \ldots, y_\beta)}(k[y_1, \ldots, y_\beta]).$$

Therefore, $a_1(R) = 0$, $a_\alpha(R) = -\alpha$ and $a_\beta(R) = -\beta$. Hence, $\delta = \max\{|a_i(R)| : a_i(R) \neq -\infty\} = \beta$. Since $a_\beta(R) < 0$, using Theorem 3.5 it follows that for all $s > \beta$,

$$\ell\left(\frac{R(n)}{(n, nt)^{[s]}_R}\right) = 2 \sum_{n=1}^{s-1} \left[ \ell\left(\frac{S}{P_1 + m^{[s]}_n}\right) + \ell\left(\frac{S}{P_2 + m^{[s]}_n}\right) - \ell\left(\frac{S}{P_1 + P_2 + m^{[s]}_n}\right) \right]$$

$$+ \sum_{n=s}^{(\beta-1)s-1} \ell\left(\frac{S}{P_1 + m^{[s]}_n}\right) + \ell\left(\frac{S}{P_2 + m^{[s]}_n}\right) - \ell\left(\frac{S}{P_1 + P_2 + m^{[s]}_n}\right)$$

$$- \sum_{n=1}^{\beta s-1} \left[ \sum_{i=0}^\beta (-1)^i \frac{h(i)_1}{i!} \binom{n + \beta - i - 1}{\beta - i} \right] + 2 \sum_{i=0}^\beta f_i (s-1)^i.$$

As the $f$-vector is $f(\Delta) = (1, \alpha + \beta, \binom{\alpha}{2} + \binom{\beta}{2}, \ldots, \binom{\alpha}{\alpha} + \binom{\beta}{\alpha}, \ldots, \binom{\beta}{\alpha + 1}, \ldots, \binom{\beta}{\beta})$ and the $h$-vector can be computed using [1, Lemma 5.1.8], substituting the values and using Corollary 3.1, it follows that for all $s > \beta$,

$$\ell\left(\frac{R(n)}{(n, nt)^{[s]}_R}\right) = 2 \sum_{n=1}^{s-1} \left[ \binom{n + \beta - 1}{\beta} + s^\alpha + \alpha \binom{n + \alpha - 1}{\alpha} - 1 \right]$$

$$+ \sum_{n=s}^{(\beta-1)s-1} \left[ \binom{n - (i-1)s + \beta - 1}{\beta} \right] - 1$$

$$+ \sum_{n=s}^{(\alpha-1)s-1} \left[ \binom{n - (i-1)s + \alpha - 1}{\alpha} \right] + \sum_{n=(\alpha-1)s}^{(\beta-1)s-1} \binom{n + s + \alpha - 1}{\alpha}$$

$$- \sum_{n=1}^{\beta s-1} \left[ \sum_{i=0}^\beta (-1)^i \frac{h(i)_1}{i!} \binom{n + \beta - i - 1}{\beta - i} \right] + 2 \sum_{i=1}^\beta \binom{\beta}{i} (s-1)^i + \sum_{i=1}^\beta \binom{\alpha}{i} (s-1)^i.$$

In particular, when $\alpha = 3$ and $\beta = 4$, we obtain that for all $s > 4$,

$$\ell\left(\frac{R(n)}{(n, nt)^{[s]}_R}\right) = \frac{61}{30} s^5 + \frac{19}{24} s^4 - \frac{1}{12} s^3 - \frac{7}{24} s^2 - \frac{9}{20} s - 1.$$
Sometimes, certain invariants of the Stanley-Reisner ring may depend on the characteristic of the ring. Triangulation of the real projective plane is one such example where the Cohen-Macaulay property of the ring is characteristic dependent. We prove that in this example, the Hilbert-Kunz function is characteristic independent.

**Example 4.7 (Triangulation of real projective plane).** Let $\Delta$ be the triangulation of the real projective plane.

Let $k$ be a field and $R$ be the corresponding Stanley-Reisner ring of $\Delta$. It is known that $R$ is Cohen-Macaulay if and only if $\text{char } k \neq 2$. The $f$-vector of $R$ is $f(\Delta) = (1, 6, 15, 10)$ and $h$-vector of $R$ is $h(\Delta) = (1, 3, 6, 0)$. Let $\text{char } k \neq 2$. Then $R$ is Cohen-Macaulay and $n(n) = -1$. Using Macaulay2 code, we obtain that for $s \geq 1$,

$$
\ell \left( \frac{R(n)}{(n, nt)[s]} \right) = 390 \binom{s + 3}{4} - 720 \binom{s + 2}{3} + 372 \binom{s + 1}{2} - 41s.
$$

We save the code in a file named as HKPolySC.m2 and make the following session in Macaulay2.

```plaintext

One may check that if char \( k = 2 \), then the \( a \)-invariant of \( R \) is negative and depth(\( R \)) = 2. Using Theorem 3.5 it follows that \( \ell(\mathcal{R}(n)/(n,nt)^{[s]}_s) \) has the same formula as in (4.1) for \( s > \delta \), where \( \delta = \max\{|a_2(R)|, |a_3(R)|\} \). This proves that the Hilbert-Kunz function is characteristic independent in this example.

5. Macaulay2 code for Cohen-Macaulay Stanley-Reisner rings

In this section we present a Macaulay2 code which uses the idea of Theorem 3.6 to calculate the value of the generalized Hilbert-Kunz function at a point. The code requires Macaulay2 packages SimplicialComplexes, SimplicialDecomposability and Depth. The code accepts the Stanley-Reisner ideal as an input. It then calculates the postulation number, after ensuring that the corresponding ring is Cohen-Macaulay, and prompts the user to enter a point according to the postulation number calculated. The value of the generalized Hilbert-Kunz function at the point is produced as an output and the user is given a choice to enter more points.

\[
\text{HKPolySC} = (\text{SCIdeal}) \rightarrow ( \\
\text{polyRing} := \text{ring} \text{SCIdeal}; \\
\text{Step 1: Check if the Stanley-Reisner ring is Cohen-Macaulay} \\
\text{if isCM}(\text{polyRing}/\text{SCIdeal}) == \text{false} \text{ then error "Stanley-Reisner ring is not Cohen-Macaulay";} \\
\text{dimSC} := \text{dim} (\text{polyRing}/\text{SCIdeal}); \\
\text{SComplex} := \text{simplicialComplex monomialIdeal} \text{SCIdeal}; \\
\text{fvect} := \text{fVector}(\text{SComplex}); \\
\text{hvect} := \text{hVector}(\text{SComplex}); \\
\text{Step 2: Calculate the derivatives of the polynomial corresponding to the} \ h\text{-vector at} \ 1 \\
\text{Diffh} = (i) \rightarrow ( \\
\text{TT} := \text{QQ}[tt]; \\
)
hPoly := sum(0..dimSC, j -> (hvect#j)*(tt^j));
for j from 1 to i do (
    hPoly = diff(tt, hPoly)
);
sub(sub(hPoly, TT/(tt-1)), QQ)

Find the list of minimal primes

MinPrimeList := primaryDecomposition SCIdeal;
numPrime := #MinPrimeList;
SubsetList := subsets toList (0..(numPrime-1));

The function CombinationList outputs the list containing subsets of \{0,\ldots,(numPrime-1)\} of cardinality \(j\)

CombinationList = (j) -> (  
jCombi = {};
for i from 0 to 2^(numPrime)-1 do (  
    if #(SubsetList#i) == j then jCombi = append(jCombi,SubsetList#i)
  );
jCombi
);

Ring required for the output polynomial

OutputRing = QQ[s];

Redefining the binomial function

binom = (aa, bb) -> (  
    if aa > 0 then return binomial(aa,bb)
    else if (aa == 0 and bb == 0) then return 1
    else return 0
);

**Step 3**: Calculate and print the postulation number
PostNum := -position(toList apply(0..dimSC, i-> dimSC-i), i-> hvect#i !=0);
<<"The postulation number is: "<< PostNum <<endl;

**Step 4:** Obtain the point from the user as an input and calculate the Hilbert-Kunz polynomial at that point

pointer := true;
while pointer == true do(
    point = read "Enter a number bigger than or equal to the absolute value of the postulation number: ";
    point = value point;
)

**Step 5:** The function $\text{FunctionF}$ calculates length as in Corollary 3.1.

$$\text{FunctionF} = (QtI, n) \rightarrow (\text{dimQt} = \text{dim}(\text{polyRing}/QtI);\text{use OutputRing};\text{if dimQt == 0 then return 1}\text{else if dimQt == 1 then return point + n}\text{else if dimQt == 2 then (}\text{if n <= point then return point}^2 + n^2 + n\text{else return (n + point + 1)*(n + point)/2}\text{)}\text{else (}\text{if n <= point then return point}^\text{dimQt} + \text{dimQt} \times \text{binom}(n+\text{dimQt}-1,\text{dimQt})\text{else if (point+1 <= n and n <= (dimQt-1)*point-1) then return point}^\text{dimQt} + \text{sum(1..(dimQt-1), i -> ((-1)^i+1)*binom(dimQt,i)*binom(n-(i-1)*point+dimQt-1,dimQt))}\text{else return binom(n+point+dimQt-1,dimQt)}\text{)}\text{);)}$$

**Step 6:** The function $\text{AltSumLength}$ calculates length as in Corollary 3.3

$$\text{AltSumLength} = (n) \rightarrow (\text{polySum} = 0;\text{for i from 1 to numPrime do (}\text{CL := toList CombinationList(i);}\text{midSum} = 0;\text{)}$$
for j from 0 to #CL-1 do 
   midIdeal = sum(0..(i-1), k -> MinPrimeList#(CL#j#k));
   midSum = midSum + FunctionF(midIdeal, n);
);
   polySum = polySum + (-1)^(i+1)*midSum;
);
   polySum
);

Step 7: Calculate the Hilbert-Kunz polynomial at the point

use OutputRing;
if PostNum == 0 then

pointer = read "Do you wish to enter one more point? (true/false): ";
pointer = value pointer;
)
)

If the $a$-invariant of the ring is known, the above code can also be used for the non Cohen-Macaulay case with minor modifications.
