Abstract. The partition function on the 3-sphere of many supersymmetric Chern–Simons-matter theories reduces, by localization, to a matrix model. We develop a new method to study these models in the M-theory limit, but at all orders in the $1/N$ expansion. The method is based on reformulating the matrix model as the partition function of an ideal Fermi gas with a non-trivial, one-particle quantum Hamiltonian. This new approach leads to a completely elementary derivation of the $N^{3/2}$ behavior for ABJM theory and $\mathcal{N} = 3$ quiver Chern–Simons-matter theories. In addition, the full series of $1/N$ corrections to the original matrix integral can be simply determined by a next-to-leading calculation in the WKB or semiclassical expansion of the quantum gas, and we show that, for several quiver Chern–Simons-matter theories, it is given by an Airy function. This generalizes a recent result of Fuji, Hirano and Moriyama for ABJM theory. It turns out that the semiclassical expansion of the Fermi gas corresponds to a strong coupling expansion in type IIA theory, and it is dual to the genus expansion. This allows us to calculate explicitly non-perturbative effects due to D0- and D2-brane instantons in the AdS background.

Keywords: conformal field theory (theory), matrix models, quantum gases
1. Introduction

One of the most interesting aspects of the AdS/CFT correspondence is that, in principle, one can use gauge theories to learn about elusive aspects of string theory and quantum gravity. For example, ABJM theory [1], as well as other supersymmetric Chern–Simons-matter (CSM) theories, are conjecturally dual to M-theory on spaces of the type $\text{AdS}_4 \times X_7$. Therefore, computations in the gauge theory side might give interesting insights into M-theory on these backgrounds.

It was shown in [2] that the partition function on the 3-sphere of CSM theories with $\mathcal{N} \geq 3$ supersymmetry reduces, via localization, to a matrix model. This result was extended to theories with $\mathcal{N} \geq 2$ supersymmetry in [3, 4]. In the case of ABJM

doi:10.1088/1742-5468/2012/03/P03001
theory, the corresponding matrix model was solved for arbitrary ’t Hooft coupling and at all orders in $1/N$ in [5], providing the first gauge theory derivation of the famous $N^{3/2}$ growth of the number of degrees of freedom of $N$ M2 branes [6]. In the last year, many results have been obtained for these matrix models, providing precision tests of the AdS$_4$/CFT$_3$ correspondence as well as beautiful field-theoretical results on supersymmetric CSM theories (see [7] for a review and a list of references).

Up to now, the ‘stringy’ side of these matrix models has been studied less intensively, but there have already been some interesting results in this direction for the ABJM theory. In [5] it was found that the genus $g$ free energies of the matrix model contain very rich information about worldsheet instantons in type IIA theory (i.e. they include non-perturbative effects in $\alpha'$). In [8], by studying the large-order behavior of the genus expansion, it was possible to identify as well non-perturbative corrections in the string coupling constant, conjecturally associated with D2-branes, or to membrane instantons in M-theory. Finally, building on the results of [5, 8], it was shown in [9] that, once worldsheet instantons are discarded, the full free energy of the ABJM matrix model is given by an Airy function. Schematically, we have

$$Z_{\text{ABJM}} \propto \text{Ai}[f(k)(N - g(k))],$$

(1.1)

where $k$ is the CS level (i.e. the inverse coupling), $f(k) \propto k^{1/3}$ is a function of $k$ determined by the large $N$ limit and $g(k)$ is a function of $k$ which shifts $N$ (see (2.14) below for a precise formula). This is a beautiful result which provides the all-orders expansion of the partition function in powers of the string length, and therefore resums the perturbative long-distance expansion for quantum superstrings.

This result raises an interesting possibility. The $N^{3/2}$ behavior of the free energy characterizes a large class of $\mathcal{N} = 3$ [10,11] and $\mathcal{N} = 2$ [12]–[15] Chern–Simons-matter theories. On the other hand, the result (1.1) says that, for ABJM theory, this behavior is just the leading term in the logarithm of the Airy function. It is then natural to propose the following

**Conjecture 1.1.** In parity-invariant supersymmetric CSM theories that display an $N^{3/2}$ growth in the number of degrees of freedom, the leading large $N$ limit and the $1/N$ corrections to the partition function on the 3-sphere add up to an Airy function, i.e. we have schematically

$$Z_{\text{CSM}} \propto \text{Ai}[f(k_a)(N - g(k_a))],$$

(1.2)

where $k_a$ are the different CS levels involved in the theory, $f(k_a)$ is a function which is determined by the leading, large $N$ limit, and $g(k_a)$ is a shift which also depends on the details of the theory (but cannot be determined by the large $N$ limit alone).

If this conjecture is true, the corresponding matrix models display a universal behavior characterized by the Airy function. For theories which are not parity-invariant, we expect the Airy function to be the crucial ingredient of the answer. It is interesting to point out that the universal role of the Airy function in summing up $1/N$ corrections was already proposed in [16] in the different but related context of five-dimensional black holes made out of M2-branes in certain Calabi–Yau compactifications\(^1\). Unfortunately, the techniques

\(^1\) We would like to thank C Vafa for discussions on this.
used to derive (1.1) for ABJM theory rely heavily on the calculation of $1/N$ corrections based on the holomorphic anomaly equation (see [5,9] for details and references). For other models it is not clear how to generalize these techniques, even in cases (like the one studied in [11]) where the planar resolvent is known explicitly.

All the results mentioned so far have been obtained in what we will call the ’t Hooft expansion of the matrix model, which corresponds to the genus expansion in type IIA superstring theory. The ’t Hooft expansion is the asymptotic expansion as $N$ goes to infinity and the ’t Hooft parameter of the model, $\lambda$, is kept fixed at large $N$:

$$N \to \infty, \quad \lambda = \frac{N}{k} \text{ fixed}. \quad (1.3)$$

However, in order to make contact with M-theory, we have to consider the M-theory expansion, i.e. the asymptotic expansion as $N$ goes to infinity in which $k$ is fixed:

$$N \to \infty, \quad k \text{ fixed}. \quad (1.4)$$

The ’t Hooft expansion of the matrix model gives some information about the M-theory expansion. For example, the all-orders result (1.1) presumably captures the all-orders expansion of the M-theory partition function in powers of the Planck length, at finite $k$. However, important contributions to the partition function in the M-theory expansion (like membrane instantons and Kaluza–Klein modes) are not directly captured in the ’t Hooft expansion, and in order to use the ABJM matrix model as a tool to explore M-theory, one should study the regime (1.4) directly. A step in this direction was taken in [10], who found a very simple method to extract the large $N$, fixed $k$ behavior of general CSM matrix models. However, in the approach of [10] it is not obvious how to compute systematically $1/N$ corrections to the leading large $N$ behavior, not to speak about exponentially small corrections in $N$.

It would then be very interesting to find a method to analyze the M-theory expansion of CSM theories, beyond the leading large $N$ contribution considered in [10]. Such a method would allow us to address the above conjecture about the universal role of the Airy function in resumming the $1/N$ corrections, and eventually could give us information about M-theoretic features of the matrix models which are not manifest in the ’t Hooft expansion.

In this paper, we make a first step in this direction and we propose a new method to analyze the matrix model of some Chern–Simons-matter theories which fulfills some of the expectations that we have just listed. The method consists of writing the partition function on the 3-sphere as the partition function of an ideal Fermi gas with a non-trivial one-particle quantum Hamiltonian. In this reformulation of the problem, the Chern–Simons level $k$ becomes Planck’s constant $\hbar$ of the quantum-mechanical problem. Since $k$ corresponds to the inverse string coupling, the semiclassical expansion of the Fermi gas is a strong coupling expansion in the type IIA theory large $N$ dual. As usual, the large $N$ limit is simply the thermodynamic limit of the gas. Our approach has the following features.

(1) The large $N$ limit of the free energy at finite $k$ is governed by the thermodynamic limit of the Fermi gas, which can be determined by a semiclassical calculation. In particular, we find a completely elementary derivation of the $N^{3/2}$ behavior of the free energy of ABJM theory, including the correct coefficient. This can be extended in a
straightforward way to $\mathcal{N} = 3$ necklace quivers, and the result for the free energy is in full agreement with the calculation in [17,18] based on the matrix model analysis of [10]. Interestingly, the relevant Fermi surface describing the thermodynamic limit of the Fermi gas is a two-dimensional polytope which characterizes the geometry of the dual tri-Sasakian spaces. In the case of ABJM theory, this Fermi surface is also a real version of the tropical curve obtained in [11].

(2) The full $1/N$ expansion of the free energy of the matrix model is determined by the first quantum correction to the semiclassical limit. In this way we reproduce the result (1.1) for ABJM theory at finite $k$, using again elementary methods in quantum statistical mechanics. Moreover, we prove our conjecture 1.1 for a large class of $\mathcal{N} \geq 3$ supersymmetric CSM theories.

(3) One can also compute exponentially suppressed effects at large $N$ which are clearly M-theoretic. In particular, we find a systematic method to determine the contribution of membrane instantons. These non-perturbative effects receive, however, corrections at all orders in the $\hbar$ expansion, and so far we can only determine them order by order in $k$ (but to all orders in the membrane winding). The strength of these corrections (i.e. the minimal membrane action) agrees with the instanton analysis of [8]. We also find contributions which are naturally interpreted as Kaluza–Klein modes (or, equivalently, as D0-branes in type IIA theory).

It follows from the last point above that, at the level of non-perturbative corrections, our method does not fully capture the M-theory expansion, since so far we are only able to determine these corrections in an expansion in $k$ around $k = 0$. In order to make contact with the true M-theory expansion one should resum the resulting series. In spite of this limitation, the Fermi gas picture gives a concrete computational method to address non-perturbative effects in these superstring theory backgrounds. In fact, the semiclassical expansion of the Fermi gas is dual to the conventional genus expansion captured by the ’t Hooft expansion of the matrix model. For example, in the ’t Hooft expansion, worldsheet instantons appear as exponential corrections in the ’t Hooft coupling, order by order in the $g_s$ expansion, while membrane corrections appear as large $N$ instantons, of order $\exp(-1/g_s)$. In the Fermi gas approach developed in this paper, membrane instantons appear as exponential corrections in the chemical potential of the gas, order by order in the $\hbar$ expansion, while worldsheet instantons appear as quantum-mechanical instanton effects of order $\exp(-1/\hbar)$.

Finally, we would like to point out that the use of Fermi gas techniques in the analysis of matrix models goes back to the solution of matrix quantum mechanics in [19], and should be familiar from the study of the $c = 1$ string (see, for example, [20]). The idea of studying the matrix integral partition function in the grand canonical ensemble appeared in [21] and was developed in detail in [22]–[24]. In particular, the semiclassical limit of the Fermi gas was already used in appendix A of [23]. The systematic application of semiclassical techniques of many-body physics in the study of these matrix integrals, which we develop in this paper, seems, however, to be new.

This paper is organized as follows. In section 2 we review previous results on the $1/N$ expansion of the ABJM matrix model in the ’t Hooft expansion, focusing on [5, 8, 9]. In section 3 we show that the matrix integral of a general class of $\mathcal{N} \geq 3$ CSM theories (necklace quivers with fundamental matter) can be written as the partition function of
an ideal Fermi gas with a non-trivial one-particle Hamiltonian. In sections 4 and 5 we present the tools to analyze the Fermi gas and we illustrate them in ABJM theory. More precisely, in section 4 we study the Fermi gas in the thermodynamic limit, by passing to the grand canonical ensemble. This makes it possible to derive the leading $N^{3/2}$ behavior of the free energy of ABJM theory, by using elementary tools in statistical mechanics. We also compute exponentially suppressed corrections to the grand canonical potential, which are interpreted as membrane instantons in M-theory. In section 5 we study the quantum corrections to the grand canonical potential. We show that, up to non-perturbative terms, a next-to-leading WKB calculation is enough to determine the full $1/N$ expansion of the canonical free energy. This provides a simple derivation of the Airy function resummation of [9]. In section 6 we extend our techniques to more general CSM theories, including necklace quivers and theories with fundamental matter. We show that, when the free energy on the 3-sphere is real, the $1/N$ expansion at fixed $k$ gets resummed by an Airy function, thus proving conjecture 1.1 for this family of examples. We also consider the ‘massive’ theory of [52], where a different $N^{5/3}$ scaling has been found for the free energy, and we rederive it with our techniques. Finally, in section 7 we conclude with some prospects for future work. In an appendix we collect some results for the grand canonical potential of ABJM theory at order $O(h^4)$.

As this paper was being prepared for submission, the paper [25] appeared which also considers ABJM theory in the grand canonical ensemble.

2. The ABJM matrix model in the ’t Hooft expansion

2.1. $1/N$ expansion and non-perturbative effects

The matrix integral describing the partition function of ABJM theory on $S^3$ is given by [2]

\[
Z_{ABJM}(N) = \frac{1}{N!^2} \int \frac{dN \mu}{(2\pi)^N} \frac{dN \nu}{(2\pi)^N} \prod_{i<j} [2 \sinh((\mu_i - \mu_j)/2)]^2 [2 \sinh((\nu_i - \nu_j)/2)]^2 \prod_{i,j} [2 \cosh((\mu_i - \nu_j)/2)]^2 \times \exp \left[ \frac{ik}{4\pi} \sum_{i=1}^{N} (\mu_i^2 - \nu_i^2) \right].
\]

(2.1)

This matrix integral can be solved in the ’t Hooft expansion (1.3) by using techniques of matrix model theory and topological string theory [26, 5]. In particular, one can obtain explicit formulae for the genus $g$ free energies appearing in the $1/N$ expansion:

\[
F(\lambda, g_s) = \sum_{g=0}^{\infty} g_s^{2g-2} F_g(\lambda),
\]

(2.2)

where the ’t Hooft coupling $\lambda$ is defined in (1.3) and

\[
g_s = \frac{2\pi i}{k}.
\]

(2.3)

The genus $g$ free energies $F_g(\lambda)$ obtained in this way are exact interpolating functions, and they can be studied in various regimes of the ’t Hooft coupling. When $\lambda \to 0$ they reproduce the perturbation theory of the matrix model around the Gaussian point. They
can also be studied in the strong coupling regime \( \lambda \to \infty \), where one can make contact with the AdS dual. In this regime it is more convenient to use the shifted variable

\[
\hat{\lambda} = \lambda - \frac{1}{24}.
\]  

(2.4)

As explained in [5], this shift is expected from type IIA and M-theory arguments [27, 28]. It turns out that, when expanded at strong coupling, the genus \( g \) free energies have the structure

\[
F_g(\hat{\lambda}) = F^p_g(\hat{\lambda}) + F^{np}_g(\hat{\lambda}).
\]  

(2.5)

The first term represents the perturbative contribution in \( \alpha' \), while the second term is non-perturbative in \( \alpha' \):

\[
F^{np}_g(\hat{\lambda}) \sim \mathcal{O}(e^{-2\pi \sqrt{2}\hat{\lambda}})
\]  

(2.6)

and it was interpreted in [5] as the contribution of worldsheet instantons in the type IIA dual. For \( F_{0,1} \), the perturbative part is of the form

\[
F^p_0(\hat{\lambda}) = \frac{4\pi^3\sqrt{2}}{3} \frac{\hat{\lambda}^{3/2}}{2}, \quad F^p_1(\hat{\lambda}) = \frac{\pi}{6} \sqrt{2\hat{\lambda}} - \frac{1}{2} \log \left[ 2\sqrt{2\hat{\lambda}} \right],
\]  

(2.7)

while for \( g \geq 2 \) one has

\[
F^p_g(\hat{\lambda}) = f_g \left( \frac{1}{\sqrt{\hat{\lambda}}} \right),
\]  

(2.8)

where

\[
f_g(x) = \sum_{j=0}^{g} c_{2g-3+j}^{(g)} x^{2g-3+j}
\]  

(2.9)

is a polynomial.

Besides the non-perturbative effects in \( \alpha' \), one can use the connection between the large-order behavior of perturbation theory and instantons to deduce the structure of non-perturbative effects in the string coupling constant. In [8] a detailed analysis showed that these effects would have the form

\[
\exp(-k\pi \sqrt{2\lambda})
\]  

(2.10)

at large \( \lambda \). These were interpreted as D2-branes wrapped around generalized Lagrangian cycles of the target geometry. We will refer to these non-perturbative effects as membrane instanton effects, since they can be interpreted as M2 instantons in M-theory [29] but they are invisible in ordinary string perturbation theory.
2.2. The partition function as an Airy function

It was shown in [9] that the genus expansion of the perturbative free energies can be resummed. In order to do that, one has to use the variable \( \lambda_{\text{ren}} = \lambda - \frac{1}{24} - \frac{1}{3k^2} \) (2.11) rather than (2.4). If we define the perturbative partition function as

\[
Z^{p}_{ABJM} = \exp \left[ \sum_{g=0}^{\infty} F_{g}^{p}(\hat{\lambda})g^{2g-2} \right] \tag{2.12}
\]

then

\[
Z^{p}_{ABJM} \propto \text{Ai} \left( \left( \frac{\pi^2 k^4}{2} \right)^{1/3} \lambda_{\text{ren}} \right), \tag{2.13}
\]

where \( \text{Ai} \) is the Airy function. This can also be written in terms of \( N \) as

\[
Z^{p}_{ABJM} \propto \text{Ai} \left[ C^{-1/3} \left( N - \frac{k}{24} - \frac{1}{3k} \right) \right], \tag{2.14}
\]

where

\[
C = \frac{2}{\pi^2 k}. \tag{2.15}
\]

As noticed in [8], the expansion resummed in (2.14) makes perfect sense for finite \( k \). Therefore, even if (2.14) was obtained from a calculation in the 't Hooft expansion, it should be part of the M-theory answer. Indeed, one of our goals in this paper is to verify this by computing \( Z^{p}_{ABJM} \) directly in the M-theory expansion.

The Airy function appearing in (2.14) gives an exact resummation of the long-distance expansion in M-theory. To see this, one has to use the dictionary relating gauge theory quantities to gravity quantities. In particular, one has to take into account the anomalous shifts relating the rank of the gauge group \( N \) to the Maxwell charge \( Q \), which in turn determines the compactification radius \( L \) [27, 28]. The relation is

\[
Q = N - \frac{1}{24} \left( k - \frac{1}{k} \right). \tag{2.16}
\]

The charge \( Q \) determines the compactification radius in M-theory according to

\[
\left( \frac{L}{\ell_{p}} \right)^{6} = 32\pi^2 Qk, \tag{2.17}
\]

where \( \ell_{p} \) is the Planck length. The shift (2.11) was interpreted in [8] as a renormalization of the expansion parameter \( \ell_{p}/L \), since it means that the natural variable is

\[
\frac{\hat{\ell}_{p}}{L} = \frac{\ell_{p}/L}{1 - 12\pi^2 (\ell_{p}/L)^{6}}^{1/6}, \tag{2.18}
\]
and then the argument of the Airy function (2.14) is given by
\[
(256 k \pi^2)^{-2/3} \left( \frac{L}{\ell_p} \right)^6.
\] (2.19)

The $1/N$ expansion of the ABJM matrix model was derived in [5] by using the holomorphic anomaly equations [30] of topological string theory. The result (2.14) was obtained in [9] by looking at the recursive structure of these equations. There is, however, a much simpler method to obtain (2.14) which exploits the wavefunction behavior of the topological string partition function. Our derivation of (2.14) in this paper does not depend at all on ideas from topological string theory, but since it is formally very similar, we will now present this simpler argument. We will rely on results and notations of [5]. Readers who are not familiar with topological string theory can skip the rest of this section and proceed to the next one.

As shown in [31], it follows from the holomorphic anomaly equations that the topological string partition function is a wavefunction on moduli space. In particular, its transformation from one symplectic frame to the other is given by a Fourier transform. This property was spelled out in detail and exploited in [32]. The main result is summarized as follows. Let
\[
\Gamma = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \in \text{SL}(2, \mathbb{Z})
\] (2.20)
be a symplectic transformation relating two different frames (we assume for simplicity that there is a single modulus in the problem). This means that the periods $(\partial_a F_0, a)$ transform as
\[
\left( \frac{\partial_a F_0}{a^2} \right) = \Gamma \left( \frac{\partial_a F_0}{a} \right).
\] (2.21)

Then, the full topological string partition function
\[
Z(a) = \exp \left[ \sum_{g=0}^{\infty} F_g(a) g_s^{2g-2} \right]
\] (2.22)
transforms as
\[
Z^{\Gamma}(a^{\Gamma}) = \int da e^{-S(a, a^{\Gamma})/g_s^2} Z(a),
\] (2.23)
where
\[
S(a, a^{\Gamma}) = -\frac{1}{2} \delta \gamma^{-1} a^2 + \gamma^{-1} a a^{\Gamma} - \frac{1}{2} \alpha \gamma^{-1} (a^{\Gamma})^2.
\] (2.24)

In the context of ABJM theory, as explained in detail in [26,5], the relevant quantities correspond to topological string computations in the so-called orbifold frame, where the natural periods are $\lambda$ (the 't Hooft coupling of the gauge theory) and the derivative $\partial_\lambda F_0$. On the other hand, the most familiar frame in topological string theory is the large radius or Gromov–Witten frame, where the natural periods are $T$ (the Kahler modulus) and the
derivative $\partial_T F^G_W$. The genus $g$ free energies in the large radius frame are given by the standard formulae:

\[
F^G_W = T^3/6 + \sum_{k>0} N_{0,k} e^{-kT}, \quad F^G_{1} = T/12 + \sum_{k>0} N_{1,k} e^{-kT},
\]

\[
F^G_{g>1} = \sum_{k>0} N_{g,k} e^{-kT},
\]

where $N_{g,k}$ are Gromov–Witten invariants in the local $\mathbb{P}^1 \times \mathbb{P}^1$ geometry (there is no constant term contribution at higher genus). The fact that the total free energy is at most cubic in $T$, up to exponentially small corrections, is a well known fact in topological string theory.

In [5], the periods in the orbifold frame were written in terms of periods in the large radius frame in order to perform analytic continuations to strong coupling. By general principles, this relation must be a symplectic transformation like (2.20). In fact, it is easy to see that the results of [5] relating the periods can be written as the following symplectic transformation:

\[
\left( \begin{array}{cc} \partial_{\tilde{\lambda}} \tilde{F}_0 & \end{array} \right) = \left( \begin{array}{cc} 0 & 1 \\ -1 & 2 \end{array} \right) \left( \begin{array}{cc} \partial_T \tilde{F}^G_W & \end{array} \right).
\]

(2.26)

where

\[
\tilde{\lambda} = \frac{4\pi^2}{c} \lambda, \quad \tilde{T} = \frac{\pi i}{2cT}, \quad c^2 = 2\pi i,
\]

and

\[
\tilde{F}_0 = F_0 - \pi^3 i \lambda, \quad \tilde{F}^G_g = (-4)^{g-1} \left( F^G_g - \delta_{g,0} \frac{\pi^2 T}{3} \right).
\]

(2.28)

Then, according to (2.23), (2.24), the total partition functions are related by the following formula:

\[
\exp \left[ F(\lambda) - \pi^3 i \lambda / g_s^2 \right] \propto \int d\tilde{T} \exp \left[ -\tilde{T}^2 / g_s^2 + \tilde{T} \lambda / g_s^2 + \tilde{F}^G_W (\tilde{T}) \right].
\]

(2.29)

Notice that, up to non-perturbative terms in $T$, this is the integral of the exponential of a cubic polynomial. Therefore we will indeed get an Airy function. Let us introduce the new variable $\mu$ through

\[
T = \frac{4\mu}{k} - \pi i.
\]

(2.30)

Then, one finds the expression

\[
\exp \left[ F(\lambda) \right] \propto \int d\mu \exp \left\{ \frac{2\mu^3}{3k\pi^2} - \mu N + \frac{k}{24} \mu + \frac{1}{3k} \mu + \mathcal{O} \left( e^{-4\mu/k} \right) \right\}
\]

\[
\propto \text{Ai} \left[ C^{-1/3} (N-B) \right] \left( 1 + \mathcal{O} \left( e^{-2\pi\sqrt{23}} \right) \right),
\]

(2.31)

where we used the following integral representation of the Airy function:

\[
\text{Ai}(z) = \frac{1}{2\pi i} \int_C dt \exp \left( \frac{t^3}{3} - zt \right),
\]

(2.32)
and $C$ is a contour in the complex plane from $e^{-i\pi/3}\infty$ to $e^{i\pi/3}\infty$. In (2.31), $C$ is given in (2.15) and

$$B = \frac{k}{24} + \frac{1}{3k}.$$  

The result of (2.31) is, of course, the expression obtained in (2.14). Notice that the first term in the shift $B$ comes from $F^{GW}_0$ in (2.28), while the second term is due to the first perturbative term in $F^{GW}_1$. The exponentially small corrections in $N$ in (2.31), which are due to the worldsheet instantons at large radius of the topological string, become, after Fourier transform, the worldsheet instantons (2.6) of the type IIA superstring.

This derivation is nice, but it seems difficult to generalize it in its current form to other Chern–Simons-matter theories and prove in this way the conjecture (1.2) for other cases. In this paper we will find a completely different approach to the derivation of the Airy function which turns out to formally equivalent to the one based on topological string theory. However, this approach can be extended to many $N \geq 3$ CSM theories and makes it possible to verify the conjecture 1.1 for many of them.

3. Chern–Simons-matter theories as Fermi gases

3.1. ABJM theory as a Fermi gas

Our Fermi gas approach is based on the following observation. The interaction term between the eigenvalues in (2.1) can be written in a different way by using the Cauchy identity:

$$\prod_{i<j}(2 \sinh((\mu_i - \mu_j)/2))[2 \sinh((\nu_i - \nu_j)/2)] \prod_{i,j}2\cosh((\mu_i - \nu_j)/2) = \det_{ij} \frac{1}{2\cosh((\mu_i - \nu_j)/2)} \sum_{\sigma \in S_N} (-1)^{\epsilon(\sigma)} \prod_i \frac{1}{2\cosh((\mu_i - \nu_{\sigma(i)})/2)}.$$  

(3.1)

In this equation, $S_N$ is the permutation group of $N$ elements and $\epsilon(\sigma)$ is the signature of the permutation $\sigma$. This identity has been used in other matrix models in [21]–[23] in order to study them in the grand canonical ensemble, as we will do here. In the context of ABJM theory, it was used in [33] in order to prove the equivalence of (2.1) and the matrix integral for $\mathcal{N} = 8$ super-Yang–Mills theory in three dimensions, when $k = 1$. The manipulations in [33] can be easily generalized to arbitrary $k$ and one obtains the following expression or the ABJM matrix model:

$$Z(N) = \frac{1}{N!} \sum_{\sigma \in S_N} (-1)^{\epsilon(\sigma)} \int \frac{d^N x}{(2\pi \kappa)^N} \frac{1}{\prod_i \cosh(x_i/2)2\cosh((x_i - x_{\sigma(i)})/2\kappa)}.$$  

(3.2)

We will derive this expression below with a different technique, which can be used for more general Chern–Simons-matter theories. The main property of (3.2) is that it makes contact with the standard formalism to study partition functions of ideal Fermi gases. Indeed, let us introduce the function

$$\rho(x_1, x_2) = \frac{1}{2\pi \kappa (2\cosh(x_1/2))^{1/2}} \frac{1}{(2\cosh(x_2/2))^{1/2}2\cosh((x_1 - x_2)/2\kappa)}.$$  

(3.3)

doi:10.1088/1742-5468/2012/03/P03001
If we interpret it as a one-particle density matrix in the position representation
\[
\rho(x_1, x_2) = \langle x_1 | \hat{\rho} | x_2 \rangle,
\] (3.4)
the matrix integral (2.1) can be written as the partition function of an ideal Fermi gas with \(N\) particles:
\[
Z(N) = \frac{1}{N!} \sum_{\sigma \in S_N} (-1)^{\ell(\sigma)} \int d^N x \prod_i \rho(x_i, x_{\sigma(i)}).
\] (3.5)

It is well known that the sum over permutations appearing in the canonical free energy of an ideal quantum gas can be written as a sum over conjugacy classes of the permutation group (see, for example, [34]). A conjugacy class is specified by a set of integers \(\{m_\ell\}\) satisfying
\[
\sum_\ell \ell m_\ell = N. \tag{3.6}
\]

Let us define
\[
Z_\ell = \int dx_1 \cdots dx_\ell \rho(x_1, x_2) \rho(x_2, x_3) \cdots \rho(x_{\ell-1}, x_\ell) \rho(x_\ell, x_1).
\] (3.7)

Then, the partition function is given by
\[
Z(N) = \sum_{\{m_\ell\}}' \prod_\ell \eta^{(\ell-1)m_\ell} Z_\ell^{m_\ell} m_\ell! \ell^{m_\ell} \tag{3.8}
\]
where the \('\) means that we only sum over the integers satisfying the constraint (3.6).

Due to the constrained sum, the canonical partition function is not easy to handle for large \(N\). As usual, the remedy is to consider the grand partition function:
\[
\Xi = 1 + \sum_{N=1}^\infty Z(N) z^N, \tag{3.9}
\]
where
\[
z = e^\mu \tag{3.10}
\]
plays the role of the fugacity and \(\mu\) is the chemical potential. The grand canonical potential is
\[
J(\mu) = \log \Xi. \tag{3.11}
\]

Notice that this potential (like the free energy) has the opposite sign to the usual conventions in statistical mechanics. A standard argument (presented, for example, in [34]) tells us that the sum over conjugacy classes in (3.8) can be written as
\[
J(\mu) = - \sum_{\ell \geq 1} Z_\ell \frac{(-z)^\ell}{\ell}. \tag{3.12}
\]

The canonical partition function is recovered from the grand canonical potential as
\[
Z(N) = \oint dz \frac{\Xi}{2\pi i z^{N+1}}. \tag{3.13}
\]
At large $N$, this integral can be computed by applying the saddle-point method to

$$Z(N) = \frac{1}{2\pi i} \int d\mu \exp[J(\mu) - \mu N]. \quad (3.14)$$

The saddle-point occurs at

$$N = \frac{\partial J}{\partial \mu} = -\sum_{\ell \geq 1} Z_\ell (-z)^\ell, \quad (3.15)$$

and defines a function $\mu_\ast(N)$. The free energy is given, at leading order as $N \to \infty$, by

$$F(N) = J(\mu_\ast) - \mu_\ast N. \quad (3.16)$$

However, it is possible to compute the $1/N$ corrections to this relation by simply computing the corrections to the full integral in (3.14). This is what we will eventually do. Notice the similarity between the traditional inverse transform (3.14) and the Fourier transform (2.31) in topological string theory.

We have then shown that the original ABJM matrix integral can be computed as the canonical partition function of a system of $N$ non-interacting fermions, where the one-particle density matrix is given by (3.3). We just have to solve the corresponding one-body problem in order to compute the relevant thermodynamic quantities of the system. Equivalently, one should compute the quantity $Z_\ell$ introduced in (3.7). This quantity can be regarded as the partition function of a classical lattice gas with $\ell$ particles in a periodic lattice with nearest-neighbor interactions, as shown in figure 1. The density matrix $\rho$ plays the role of the classical transfer matrix of the system (see, for example, chapter 12 of [35]). It defines a symmetric kernel

$$\langle x | \hat{\rho} | \phi \rangle = \int dx' \rho(x, x') \phi(x'), \quad (3.17)$$

so that

$$Z_\ell = \text{Tr} \hat{\rho}^\ell. \quad (3.18)$$

It is easy to see that this kernel is a non-negative Hilbert–Schmidt operator. Therefore it has a discrete, positive spectrum:

$$\hat{\rho} | \phi_n \rangle = \lambda_n | \phi_n \rangle, \quad n = 0, 1, \ldots, \quad (3.19)$$
where \(|\phi_n\rangle\) are orthonormal eigenfunctions and we assume that
\[ \lambda_0 \geq \lambda_1 \geq \lambda_2 \geq \cdots. \]  
(3.20)

We can then write the density matrix as
\[ \hat{\rho} = \sum_{n \geq 0} \lambda_n |\phi_n\rangle \langle \phi_n|. \]  
(3.21)

In terms of these eigenvalues we have
\[ Z_\ell = \sum_{n \geq 0} \lambda_n^\ell. \]  
(3.22)

When \(\ell\) is large, this sum is dominated by the largest eigenvalue \(\lambda_0\):
\[ Z_\ell \approx \lambda_0^\ell, \quad \ell \gg 1. \]  
(3.23)

It also follows from this representation that the grand canonical partition function is given by a Fredholm determinant:
\[ \Xi = \det(1 + z\hat{\rho}) = \prod_{n \geq 0}(1 + z\lambda_n). \]  
(3.24)

Instead of using the formulation of the lattice problem in terms of the density matrix operator, we can introduce a quantum Hamiltonian in the standard way:
\[ \hat{\rho} = e^{-\frac{1}{2}\hat{H}}. \]  
(3.25)

This leads to the well-known equivalence between the partition function of a classical lattice gas (3.18) and the propagator of a quantum particle in \(\ell\) units of discretized time [35,36]. We can then write
\[ Z_\ell = \text{Tr} e^{-\ell\hat{H}}. \]  
(3.26)

To find the Hamiltonian corresponding to the ABJM matrix model, we first write the density matrix (3.3) as
\[ \hat{\rho} = e^{-1/2U(\hat{q})}e^{-T(\hat{p})}e^{-1/2U(\hat{q})}. \]  
(3.27)

In this equation, \(\hat{q}, \hat{p}\) are canonically conjugate operators:
\[ [\hat{q}, \hat{p}] = i\hbar, \]  
(3.28)

and
\[ \hbar = 2\pi k. \]  
(3.29)

This is a key aspect of this formalism: \(\hbar\) is the inverse coupling constant of the gauge theory/string theory. Therefore semiclassical WKB expansions in the Fermi gas correspond to strong coupling expansions in gauge theory/string theory. The potential \(U(q)\) in (3.27) is given by
\[ U(q) = \log \left(2\cosh\frac{q}{2}\right), \]  
(3.30)
and the kinetic term $T(p)$ is given by the same function:

$$T(p) = \log \left(2 \cosh \frac{p}{2}\right). \quad (3.31)$$

The peculiar kinetic term (3.31) can be regarded as a non-trivial dispersion relation interpolating between the quadratic behavior of a non-relativistic particle at small $p$:

$$T(p) \sim \log(2) + \frac{p^2}{8}, \quad p \to 0, \quad (3.32)$$

and the linear behavior of an ultra-relativistic particle at large $p$:

$$T(p) \sim \frac{|p|}{2}, \quad |p| \to \infty. \quad (3.33)$$

Notice that, as is standard for Hamiltonians defined by transfer matrices at finite lattice spacing [35,36], the quantum operator $\hat{H}$ defined by (3.25) and (3.27) differs from

$$T(\hat{p}) + U(\hat{q}) \quad (3.34)$$

in $\hbar$ corrections. There is a very elegant method to obtain these corrections based on the phase-space or Wigner approach to quantization. This method will also be extremely useful in setting the semiclassical WKB expansion of our thermodynamic problem. We first recall that the Wigner transform of an operator $\hat{A}$ is given by (see [37] for a detailed exposition of phase-space quantization)

$$A_W(q,p) = \int dq' \left\langle q - \frac{q'}{2} \left| \hat{A} \left| q + \frac{q'}{2} \right. \right\rangle e^{ipq'/\hbar}. \quad (3.35)$$

The Wigner transform of a product is given by the $\star$-product of their Wigner transforms:

$$(\hat{A} \hat{B})_W = A_W \star B_W \quad (3.36)$$

where the star operator is given as usual by

$$\star = \exp \left[ i\hbar \left( \frac{\partial}{\partial q} \frac{\partial}{\partial p} - \frac{\partial}{\partial p} \frac{\partial}{\partial q} \right) \right], \quad (3.37)$$

and is invariant under linear canonical transformations. Another useful property is that

$$\text{Tr} \hat{A} = \int \frac{dp\,dq}{2\pi\hbar} A_W(q,p). \quad (3.38)$$

In order to calculate the $\hbar$ corrections to the Hamiltonian, we consider the Wigner transform of the density matrix (3.27). By using (3.36) we find

$$\rho_W = e^{-\frac{1}{2}U(q)} \star e^{-T(p)} \star e^{-\frac{1}{2}U(q)}. \quad (3.39)$$

Let us note that the partition function depends only on the eigenvalues $\lambda_n$ of $\hat{\rho}$ (or, equivalently, on the traces $Z_\ell = \text{Tr} \hat{\rho}^\ell$). Therefore there is the following freedom in the choice of $\hat{\rho}$:

$$\hat{\rho} \rightarrow \hat{V} \hat{\rho} \hat{V}^{-1} \quad (3.40)$$

doi:10.1088/1742-5468/2012/03/P03001
which translates into
\[ \rho_W(q, p) \to V_W(q, p) \star \rho_W(q, p) \star (V^{-1})_W(q, p) \] (3.41)
after the Wigner transform. Equation (3.39) defines the Wigner transform of our Hamiltonian through
\[ \rho_W = e^{-H_W}, \] (3.42)
where the \( \star \)-exponential is defined by
\[ \exp_\star(A) = 1 + A + \frac{1}{2} A \star A + \cdots. \] (3.43)
The quantum Hamiltonian \( H_W \) can be computed by using the Baker–Campbell–Hausdorff formula, as applied to the \( \star \)-product. One finds
\[ H_W(q, p) = T + U + \frac{1}{12} [T, [T, U]]_\star + \frac{1}{24} [U, [T, U]]_\star + \cdots \]
\[ = T(p) + U(q) - \frac{\hbar^2}{12} (T'(p))^2 U''(q) + \frac{\hbar^2}{24} (U'(q))^2 T''(p) + O(\hbar^4), \] (3.44)
where we have used the fact that, at leading order in \( \hbar \), the Moyal bracket is the Poisson bracket:
\[ [A, B]_\star \equiv A \star B - B \star A = i\hbar \{A, B\} + O(\hbar^2). \] (3.45)
Further corrections to (3.44) can be computed to any desired order, see (A.1) for the result at order \( O(\hbar^4) \).

3.2. More general Chern–Simons-matter theories

The identification of the matrix model of ABJM theory as the partition function of a Fermi gas can also be made for more general \( \mathcal{N} \geq 3 \) Chern–Simons-matter theories. We will set up the formalism for the necklace quivers with \( r \) nodes considered in [38, 39], and with fundamental matter in each node (see figure 2). These theories are given by
\[ U(N)_{k_1} \times U(N)_{k_2} \times \cdots \times U(N)_{k_r} \] (3.46)
Chern–Simons quiver. Each node will be labeled with the letter \( a = 1, \ldots, r \). There are bifundamental chiral superfields \( A_{aa+1}, B_{aa-1} \) connecting adjacent nodes, and in
addition we will suppose that there are \( N_f \) matter superfields \((Q_a, \tilde{Q}_a)\) in each node, in the fundamental representation. We will write
\[
k_a = n_a k,
\]
and we will assume that
\[
\sum_{a=1}^r n_a = 0.
\]

According to the general localization computation in [2], the matrix model computing the S\(^3\) partition function of a necklace quiver is given by
\[
Z(N) = \frac{1}{(N!)^r} \int \prod_{a,i} d\lambda_{a,i} \exp\left[i(n_a k/4\pi \lambda_{a,i}^2)\right] \prod_{a=1}^r \prod_{i<j}^r \left[2 \sinh((\lambda_{a,i} - \lambda_{a,j})/2)\right]^{N_f} \prod_{i,j}^r 2 \cosh((\lambda_{a,i} - \lambda_{a+1,j})/2).
\]

This matrix model is very similar to the \( \hat{A}_{r-1} \) models considered in, for example, [22, 40] and one can use a very similar strategy in order to rewrite them as Fermi gases. First of all, we define a kernel corresponding to a pair of connected nodes \((a, b)\) by
\[
K_{ab}(x', x) = \frac{1}{2\pi k} \exp\left\{i(n_b x^2/4\pi k)\right\} \left[2 \cosh(x/2k)\right]^{-N_f},
\]
where we set \( x = \lambda/k \). The grand canonical partition function corresponding to the above matrix model is defined as in (3.9). Then, if we use the Cauchy identity (3.1), a simple generalization of the above arguments makes it possible to write it again as a Fredholm determinant (3.24), where now [22]
\[
\hat{\rho} = \hat{K}_1 \hat{K}_{12} \cdots \hat{K}_{r-1,r}
\]
is the product of the kernels (3.50) around the quiver. Therefore, we can apply exactly the same techniques that we used before in ABJM theory. In a sense, we are ‘integrating out’ \( r - 1 \) nodes of the quiver in order to define an effective theory in the \( r \)th node, but with a complicated Hamiltonian which takes into account the other nodes.

This idea can be made very concrete by looking at the Wigner transform of the operator \( \hat{\rho} \) in (3.51). We first compute the Wigner transform of the kernel (3.50):
\[
K_{ab}^W(q, p) = \frac{1}{2 \cosh(p/2)} \star \frac{e^{i n_b q^2/2\hbar}}{[2 \cosh(q/2k)]^{N_f}},
\]
where the \( \hbar \) in the \( \star \)-product is given again by (3.29). Let us note that
\[
e^{i n_q q^2/2\hbar} \star f(p) \star e^{-i n_q q^2/2\hbar} = f(e^{i n_q q^2/2\hbar} \star p \star e^{-i n_q q^2/2\hbar}) = f(e^{ad_{\star}[i n_q q^2/2\hbar]} p) = f(p - nq),
\]
where we used that
\[
[q^2, p]_\star = 2i\hbar q.
\]
We obtain then for the Wigner transform of the density operator (3.51)

\[ \rho_{W}(q,p) = \frac{1}{2 \cosh(p/2)} \times \frac{1}{2 \cosh(q/2k)^{N_{f_1}}} \times \frac{1}{2 \cosh((p-n_1q)/2)} \]

\[ \times \frac{1}{2 \cosh(q/2k)^{N_{f_2}}} \times \frac{1}{2 \cosh(p-(n_1+n_2)q)/2} \times \frac{1}{2 \cosh(q/2k)^{N_{f_3}}} \]

\[ \times \cdots \times \frac{1}{2 \cosh(p-(n_1+\cdots+n_{r-1})q)/2} \times \frac{1}{2 \cosh(q/2k)^{N_{f_r}}} \]

(3.55)

where we used (3.48). For necklace theories without fundamental matter this is simply

\[ \rho_{W}(q,p) = \frac{1}{2 \cosh(p/2)} \times \frac{1}{2 \cosh(p-n_1q)/2} \]

\[ \times \frac{1}{2 \cosh(p-(n_1+n_2)q)/2} \times \cdots \times \frac{1}{2 \cosh(p-(n_1+\cdots+n_{r-1})q)/2} \]

(3.56)

In particular, for the ABJM necklace \((-k,k)\) with fundamental matter \(N_{f_1} = N_{f_2} = N_{f}\)

first considered in [41]–[43], we have

\[ \rho_{W}(q,p) = \frac{1}{2 \cosh(p/2)} \times \frac{1}{2 \cosh(p+q)/2} \times \frac{1}{2 \cosh(q/2k)^{N_{f}}} \]

(3.57)

If we perform a canonical transformation

\[ p \to -q, \quad q \to p+q \]

(3.58)

and we conjugate by \([2 \cosh(q/2)]^{1/2}\) to obtain a symmetric kernel, we get the equivalent representation:

\[ \rho_{W}(q,p) = \frac{1}{[2 \cosh(q/2)]^{1/2}} \times \frac{1}{2 \cosh(p+q)/2k} \times \frac{1}{2 \cosh(p/2)} \times \frac{1}{2 \cosh(p+q)/2k}^{N_{f}} \]

(3.59)

which, for \(N_{f} = 0\), agrees with the result (3.39). In this way, we have reduced the general necklace quiver theory to an ideal Fermi gas whose one-particle quantum Hamiltonian is defined by the above density matrices through (3.42).

Notice that, in general, the density operators \(\hat{\rho}\) are not Hermitian, and correspondingly \(H_{W}\) is generally not real. This reflects the fact that the free energy on the 3-sphere of these CSM theories is, in general, complex.

4. Thermodynamic limit

It is well known that the thermodynamic limit of an ideal quantum gas can be evaluated by treating the one-particle problem in the semiclassical or WKB approximation. Moreover, the \(1/N\) corrections to the thermodynamic limit can be obtained by studying the quantum corrections to the semiclassical limit. In this section we will present general results about the thermodynamic limit and we will illustrate them in ABJM theory. More general theories will be considered in section 6.
4.1. The thermodynamic limit of ideal Fermi gases

In the following we will need several standard results in the analysis of ideal quantum gases. The distribution operator at zero temperature is given by

\[ \hat{n}(E) = \theta(E - \hat{H}) \]  

where \( \theta(x) \) is the Heaviside step function. The trace of this operator gives the function \( n(E) \), counting the number of eigenstates whose energy is less than \( E \):

\[ n(E) = \text{Tr} \hat{n}(E) = \sum_n \theta(E - E_n). \]  

(4.2)

Notice that

\[ E_n = -\log \lambda_n, \]  

(4.3)

where \( \lambda_n \) are the eigenvalues (3.19) of the density matrix. The density of eigenstates is defined by

\[ \rho(E) = \frac{dn(E)}{dE} = \sum_n \delta(E - E_n). \]  

(4.4)

The one-particle canonical partition function is then given by the standard formula:

\[ Z_\ell = \int_0^\infty dE \rho(E) e^{-\ell E}, \]  

(4.5)

while the grand canonical potential of the \( N \)-particle system is given by

\[ J(\mu) = \int_0^\infty dE \rho(E) \log(1 + ze^{-E}). \]  

(4.6)

Let us now consider the thermodynamic limit of the system, when \( N \to \infty \). In this regime, the behavior of the system is semiclassical and the spectrum of the one-particle Hamiltonian is encoded in the functions \( n(E), \rho(E) \). The thermodynamic limit is governed by the behavior of these functions as \( E \gg 1 \). We notice that, if \( n(E) \approx CE^s, E \gg 1 \),

\[ n(E) \approx C E^s, \quad E \gg 1, \]  

(4.7)

then the grand canonical potential is given by

\[ J(\mu) \approx sC \int_0^\infty \log(1 + ze^{-E}) E^{s-1} dE = -CT(s + 1)\text{Li}_{s+1}(-e^\mu), \]  

(4.8)

where \( \text{Li}_s \) is the usual polylogarithm function. The number of particles is related to the chemical potential by

\[ N(\mu) \approx CT(s + 1)\text{Li}_s(-e^\mu), \]  

(4.9)

and large \( N \) corresponds to large \( \mu \). In this regime, we have

\[ J(\mu) \approx \frac{C}{s+1} \mu^{s+1}, \quad N(\mu) \approx C \mu^s. \]  

(4.10)

The second equation defines \( \mu \) as a function of \( N \), and we deduce from (3.16) that the canonical free energy is given, as \( N \to \infty \), by

\[ F(N) \approx -\frac{s}{s+1} C^{-1/s} N^{(s+1)/s}. \]  

(4.11)
These formulae should be familiar from the elementary theory of ideal quantum gases. For example, the textbook ideal Fermi gas in three dimensions has \( s = \frac{3}{2} \).

To determine the value of \( s \) for a given system we notice that, in the semiclassical limit, the trace is replaced by an integral over phase space:

\[
\text{Tr} \rightarrow \int \frac{dq \, dp}{2\pi \hbar}
\]

which gives the standard semiclassical formula:

\[
n(E) \approx \int \frac{dp \, dq}{2\pi k} \theta(E - H(q, p)) = \frac{\text{Vol}(E)}{2\pi \hbar},
\]

i.e. the number of eigenstates is just given by the volume of phase space. The surface

\[
H(q, p) = E
\]

is just the Fermi surface of the system. For a one-dimensional ideal gas whose one-particle Hamiltonian is of the form

\[
H \sim A|p|^\alpha + B|q|^\beta
\]

we have

\[
s = \frac{1}{\alpha} + \frac{1}{\beta}.
\]

This will be useful later on.

### 4.2. A simple derivation of the \( N^{3/2} \) behavior in ABJM theory

We can now study the thermodynamic limit of the partition function of ABJM theory. In this case, the Hamiltonian appearing in the semiclassical formula (4.13) is just given by the classical counterpart of (3.34):

\[
H_{cl}(q, p) = T(p) + U(q) = \log(2 \cosh(p/2)) + \log(2 \cosh(q/2)).
\]

Here we have neglected the \( \hbar \) corrections appearing in \( H_W \). It is easy to show that the minimum energy is

\[
E_0 = 2 \log 2,
\]

which corresponds to the maximal eigenvalue of the density matrix:

\[
\lambda_0 = \frac{1}{4}.
\]

This is the semiclassical value given by the leading WKB approximation, and it will be corrected quantum-mechanically. In the large \( E \) regime, the discrete spectrum ‘condenses’ along a cut in the complex plane and \( \lambda_0 \) signals the endpoint of the cut.

In order to proceed with the analysis of the thermodynamic limit, we should determine the Fermi surface

\[
H_{cl}(q, p) = E
\]

controlling the density of eigenvalues. We show the shape of this surface in figure 3 for \( E = 4 \) (left) and \( E = 100 \) (right). It is clear that in the thermodynamic limit, when \( E \) is...
large, the surface can be approximated by considering the values of $U(q), T(p)$ for $q, p$ large. In this regime we have
\[ U(q) \approx \frac{|q|}{2}, \quad |q| \to \infty, \quad T(p) \approx \frac{|p|}{2}, \quad |p| \to \infty, \]
so that (4.20) is approximately given by
\[ |q| + |p| = 2E, \]
as is manifest in the graphic on the right in figure 3. From (4.15) and (4.16) we deduce that
\[ s = 2. \]
Since
\[ \text{Vol}(E) \approx 8E^2, \]
the number of states is given by
\[ n(E) \approx \frac{2}{\pi^2 k} E^2. \]
By comparing with (4.7), we find
\[ C = \frac{2}{\pi^2 k}. \]
The equation (4.11) gives immediately
\[ F(N) \approx -\frac{\pi \sqrt{2k}}{3} N^{3/2}. \]
This is exactly the result first found in [5] using the ’t Hooft expansion of the matrix model. The derivation presented here is, however, completely elementary and relies on basic notions of quantum statistical mechanics: the $3/2$ scaling of the number of degrees of freedom is nothing other than scaling of the free energy of an ultra-relativistic gas of...
one-dimensional fermions in a linearly confining potential. No matrix model techniques are needed. In this sense, our derivation is even simpler than the one presented in [10], which required some detailed analysis of the eigenvalue interaction in the matrix integral.

We would like to emphasize that the above result (4.27) provides the right large $N$ behavior of the system at finite $k$. This is because the true expansion parameter in the semiclassical expansion is $\hbar/E$, which is small for large $E$ even at finite $\hbar$. This can be proved rigorously for some spectral problems defined by kernels of the form (3.3) [44] and we will verify it in section 5 by a detailed analysis of the WKB expansion.

4.3. Large $N$ corrections

One advantage of the statistical–mechanical framework presented here is that it makes it possible to compute corrections to the thermodynamic limit in a systematic way. To start the study of these corrections, we now look at the thermodynamics of the Fermi gas of ABJM theory in the semiclassical approximation, but taking into account the exact value of the volume of phase space (i.e. we go beyond the polygonal approximation in (4.22)). As expected, this gives subleading and exponentially suppressed corrections at large $N$.

The computation of the exact volume is equivalent to computing all the $Z_\ell$ exactly in the semiclassical approximation and resumming the resulting series (3.12). Using that

$$\int_{-\infty}^{\infty} \frac{d\xi}{(2 \cosh(\xi/2))^\ell} = \frac{\Gamma^2(\ell/2)}{\Gamma(\ell)}$$

we find

$$Z_\ell \approx \frac{1}{\hbar} Z_{\ell}^{(0)},$$

where

$$Z_{\ell}^{(0)} = \int \frac{dp}{2\pi} \frac{dq}{2\pi} e^{-\ell H_{cl}(p,q)} = \frac{1}{2\pi} \frac{\Gamma^4(\ell/2)}{\Gamma^2(\ell)}.$$  

Therefore

$$J(\mu) \approx \frac{1}{k} J_0(\mu)$$

where

$$J_0(\mu) = -\sum_{\ell=1}^{\infty} \frac{(-z)^\ell}{4\pi^2} \frac{\Gamma^4(\ell/2)}{\ell \Gamma^2(\ell)} \left( 1, \frac{1}{2}; \frac{1}{2}; \frac{1}{2}; 1, \frac{3}{2}; \frac{z^2}{16} \right) - \frac{z^2}{8\pi^2} 4 F_3 \left( 1, 1, 1; \frac{3}{2}, \frac{3}{2}, \frac{1}{2}; \frac{z^2}{16} \right).$$

This function has a branch cut in the $z$ plane at $(-\infty, -4]$. This is expected: indeed, from (3.24) there should be a cut starting at

$$z = -\lambda_0^{-1} = -4,$$

indicating the condensation of eigenvalues for the one-particle density matrix. The function (4.32) has the following asymptotics for large $\mu$:

$$J_0(\mu) = \frac{2\mu^3}{3\pi^2} + \frac{\mu}{3} + \frac{2\zeta(3)}{\pi^2} + J_0^{np}(\mu).$$

\[\text{doi:10.1088/1742-5468/2012/03/P03001}\]
The leading, cubic term in $\mu$ is the one responsible for the behavior (4.27). The subleading term in $\mu$ gives a correction of order $N^{1/2}$ to the leading behavior (4.27). The last, non-perturbative term involves an infinite power series of exponentially small corrections in $\mu$. They have the structure

$$J^{\text{np}}_0(\mu) = \sum_{\ell=1}^{\infty} (a_{0,\ell} \mu^2 + b_{0,\ell} \mu + c_{0,\ell}) e^{-2\ell \mu}. \tag{4.35}$$

Explicitly, one finds for the very first orders

$$J^{\text{np}}_0(\mu) = \frac{2}{3\pi^2} (6 - \pi^2 + 6\mu - 6\mu^2)e^{-2\mu} + \frac{1}{2\pi^2} (25 - 6\pi^2 - 66\mu - 36\mu^2)e^{-4\mu} + \mathcal{O}(\mu^2 e^{-6\mu}). \tag{4.36}$$

The non-perturbative part of the grand potential leads to exponentially small corrections in $N$ in the canonical free energy. In fact, using (4.10) we find that, once evaluated at the saddle-point,

$$\exp(-2\mu) \approx \exp(-\sqrt{2\pi k} N^{1/2}). \tag{4.37}$$

This is precisely the action for membrane instantons (2.10) found in [8] as large $N$ instantons of the matrix model in the 't Hooft expansion. We conclude that the exponentially small corrections in $\mu$, which in this approach appear already in the semiclassical approximation, correspond, in fact, to non-perturbative corrections in the genus expansion and should be identified as membrane instanton contributions.

As mentioned before, the calculation of these exponentially small corrections to the grand canonical potential is equivalent to the exact calculation of the volume (4.13) of classical phase space. To see this, we notice that we can write this volume as a period of the 1-form $p \mathsf{d}q$ along the curve (4.14)

$$\text{Vol}(E) = \oint_{H_c(q,p)=E} p \mathsf{d}q. \tag{4.38}$$

This period vanishes at the point $E = E_0$. It turns out that its exact value is given by a Meijer function:

$$\text{Vol}(E) = \frac{e^E}{\pi} G_{2,3}^{3,3} \left( \frac{e^{2E}}{16} \left| \begin{array}{ccc} \frac{1}{2}, & \frac{1}{2}, & \frac{1}{2} \\ 0, & 0, & -\frac{1}{2} \end{array} \right. \right) - 4\pi^2. \tag{4.39}$$

This leads to the following large $E$ expansion of the number of states:

$$n(E) = \frac{2E^2}{\pi^2 k} - \frac{1}{3k} + \mathcal{O}(Ee^{-2E}) + \mathcal{O}(\hbar), \tag{4.40}$$

where the first term agrees, of course, with the semiclassical calculation at large $E$ done before. One can then check that the expression (4.6) for the grand canonical potential reproduces (4.32), once the density obtained from (4.39) is used.

doi:10.1088/1742-5468/2012/03/P03001
4.4. Relation to previous results

The semiclassical limit of the one-particle Hamiltonian turns out to be closely related to the planar limit of ABJM theory studied in [26,5,8].

First of all, the semiclassical quantization of the one-dimensional problem leads to the Fermi surface:

\[ T(p) + U(q) = E \]

which is, in fact, a curve in phase space. Let us now make the following change of variables:

\[ x = \frac{q}{2} + \frac{p}{2}, \quad y = p + \pi i, \]

which, up to an overall constant, preserves the form \( p \, dq \). In terms of the exponentiated variables

\[ X = e^{q/2+p/2}, \quad Y = -e^p. \]

the Fermi surface (4.41) is

\[ Y + \frac{X^2}{Y} - X^2 + i\kappa X - 1 = 0, \]

where

\[ i\kappa = e^E. \]

The curve (4.44) is nothing but the spectral curve of the ABJM matrix model written down in, for example, [5]. The minimal energy \( E_0 \) given in (4.18) corresponds to the conifold point \( \kappa = 4i \) studied in detail in [5]. The volume of phase space, which as we remarked after (4.38) is a vanishing period at \( E = E_0 \), is actually proportional to the conifold period studied in [8]. Finally, the large energy limit, in which the Fermi surface becomes a polygon, is nothing other than the tropical limit of the spectral curve, studied in [11].

5. Quantum corrections

In section 4.4 we have recalled the semiclassical limit of ideal Fermi gases, and we have studied in detail the case of ABJM theory. We now study the corrections to the semiclassical limit in a systematic and general way. These corrections lead to a power series in \( \hbar^2 \propto k^2 \) for the grand canonical partition function. As we will see, only the first \( \hbar^2 \) correction contributes to the asymptotic series in \( 1/N \) of the canonical free energy, up to an additive function of \( k \) but independent of \( N \). This means that we can compute the full series of \( 1/N \) corrections to the original matrix model partition function, up to an overall, \( N \)-independent constant. However, the exponentially small terms in \( \mu \) appearing in \( J(\mu) \) receive corrections to all orders in \( \hbar^2 \).
5.1. Quantum-corrected Hamiltonian and Wigner–Kirkwood expansion

There are two sources of \( \hbar \) corrections in the one-body problem appearing in our Fermi gas formulation. The first one appears already in the Hamiltonian \( \hat{H} \): when we compute \( \hat{H} \) starting from (3.27), the non-commutativity of the operators in (3.27) leads to \( O(\hbar) \) corrections to (3.34). This first source of corrections is nicely encoded in the Wigner transform (3.44). Another source of corrections is due to the standard semiclassical expansion of the density of eigenvalues. We now present a formalism to treat in a systematic way both types of corrections. This formalism is a generalization of the standard Wigner–Kirkwood \( \hbar \) expansion [45,46] in quantum statistical mechanics, and it incorporates general, \( \hbar \)-dependent Hamiltonians. As in section 3.1, the formalism is most conveniently formulated in the phase-space approach to quantization and it has been developed in the context of many-body physics. The most elegant presentation is due to Voros [47,48] (see also [49]).

Let \( \hat{H} \) be the Hamiltonian of a one-particle, one-dimensional quantum system, and let \( H_W \) be its Wigner transform. We would like to compute systematically the \( \hbar \) expansion of the canonical partition function and of the density of states. Following [48] we notice that it is possible to expand any function \( f(\hat{H}) \) of \( \hat{H} \) around \( H_W(q,p) \), which is a \( c \)-number. This gives

\[
f(\hat{H}) = \sum_{r \geq 0} \frac{1}{r!} f^{(r)}(H_W) (\hat{H} - H_W(q,p))^r. \tag{5.1}
\]

The semiclassical expansion of this object is obtained simply by evaluating its Wigner transform and we obtain

\[
f(\hat{H})_W = \sum_{r \geq 0} \frac{1}{r!} f^{(r)}(H_W) G_r \tag{5.2}
\]

where

\[
G_r = [(\hat{H} - H_W(q,p))^r]_W \tag{5.3}
\]

and the Wigner transform is evaluated at the same point \( q,p \). Of course, one has

\[
G_0 = 1, \quad G_1 = 0, \tag{5.4}
\]

and the quantities \( G_r \) for \( r \geq 2 \) can be computed again by using (3.36). They have an \( \hbar \) expansion of the form

\[
G_r = \sum_{n \geq [(r+2)/3]} \hbar^{2n} G_r^{(n)}, \quad r \geq 2. \tag{5.5}
\]

This means, in particular, that to any order in \( \hbar^2 \), only a finite number of \( G_r \)'s are involved. One finds, for the very first orders [48,49],

\[
G_2 = -\frac{\hbar^2}{4} \left[ \frac{\partial^2 H_W}{\partial q^2} \frac{\partial^2 H_W}{\partial p^2} - \left( \frac{\partial^2 H_W}{\partial q \partial p} \right)^2 \right] + O(\hbar^4),
\]

\[
G_3 = -\frac{\hbar^2}{4} \left[ \left( \frac{\partial H_W}{\partial q} \right)^2 \frac{\partial^2 H_W}{\partial p^2} + \left( \frac{\partial H_W}{\partial p} \right)^2 \frac{\partial^2 H_W}{\partial q^2} - 2 \frac{\partial H_W}{\partial q} \frac{\partial H_W}{\partial p} \frac{\partial^2 H_W}{\partial q \partial p} \right] + O(\hbar^4). \tag{5.6}
\]
One can then apply this method to compute the semiclassical expansion of any function of the Hamiltonian operator. For example, when applied to (4.2), one finds

\[ \hat{n}(E)_W = \theta(E - H_W) + \sum_{r=2}^{\infty} \frac{1}{r!} G_r \delta^{(r-1)}(E - H_W), \]  

so therefore

\[ n(E) = \int_{H_W(q,p) \leq E} \frac{dq dp}{2 \pi \hbar} + \sum_{r=2}^{\infty} \frac{1}{r!} \int \frac{dq dp}{2 \pi \hbar} G_r \delta^{(r-1)}(E - H_W). \]  

When applied to the canonical density matrix at inverse temperature \( \beta \), one finds

\[ (e^{-\beta \hat{H}})_W = \left( \sum_{r=0}^{\infty} \frac{(-\beta)^r}{r!} G_r \right) e^{-\beta H_W}. \]  

The standard Wigner–Kirkwood \( \hbar \) expansion of the canonical partition function \([45,46]\) is just a particular case of (5.9) when the Hamiltonian is

\[ \hat{H} = \frac{\hat{p}^2}{2} + U(\hat{q}). \]  

Let us now apply this formalism to our case. First of all, the quantum-corrected Hamiltonian is given by a power series in \( \hbar \) of the form

\[ H_W = \sum_{n \geq 0} \hbar^{2n} H_W^{(n)}. \]  

At leading order we find, of course, the classical Hamiltonian (4.17):

\[ H_W^{(0)} = T(p) + U(q), \]  

the \( \mathcal{O}(\hbar^2) \) term is written down in (3.44) and the \( \mathcal{O}(\hbar^4) \) term can be found in (A.1). The one-particle canonical partition function can then be computed as a power series in \( \hbar \):

\[ Z_\ell = 1 + \sum_{n=0}^{\infty} Z_\ell^{(n)} \hbar^{2n}, \]  

where

\[ Z_\ell^{(0)} = \left( \int \frac{dq dp}{2 \pi} e^{-\ell H_\lambda} \right) \]  

is the classical limit. The expansion is obtained by grouping \( \hbar^2 \) corrections in the expression

\[ Z_\ell = \frac{1}{\hbar} \sum_{r \geq 0} \frac{(-\ell)^r}{r!} \int \frac{dq dp}{2 \pi} G_r e^{-\ell H_W}. \]  

The power series in \( \hbar \) for \( Z_\ell \) leads to the following power series in \( k \) for \( J(\mu) \):

\[ J(\mu) = \frac{1}{k} \sum_{n=0}^{\infty} J_n(\mu) k^{2n}, \]  

doi:10.1088/1742-5468/2012/03/P03001
where
\[ J_n(\mu) = -(2\pi)^{2n-1} \sum_{\ell=1}^{\infty} \frac{(-z)_\ell}{\ell} Z_{\ell}^{(n)}. \] (5.17)

As an illustration of the above general considerations, we will now calculate the first \( \hbar^2 \) correction to the semiclassical result of ABJM theory obtained in section 4.3. Using the formulae above, we find

\[ Z^{(1)}_{\ell} = \int \frac{dq}{2\pi} \frac{dn}{2\pi} e^{-\ell H_{cl}^{(1)}} \left\{ -\ell H_{cl}^{(1)} + \frac{\ell^2}{2} G_2^{(1)} - \frac{\ell^3}{6} G_3^{(1)} \right\} \]

\[ = -\ell \int \frac{dq}{2\pi} \frac{dn}{2\pi} e^{-\ell H_{cl}^{(1)}} \left[ \frac{1}{24} (U'(q))^2 T''(p) - \frac{1}{12} (T'(p))^2 U''(q) \right] \]

\[ + \int \frac{dq}{2\pi} \frac{dn}{2\pi} e^{-\ell H_{cl}^{(1)}} \left\{ \frac{\ell^3}{24} [(U'(q))^2 T''(p) + U''(q)(T'(p))^2] - \frac{\ell^2}{8} U''(q) T''(p) \right\}. \] (5.18)

To evaluate these coefficients, we need the integral appearing in (4.28), as well as

\[ \int_{-\infty}^{\infty} \frac{d\xi}{(2\cosh(\xi/2))^\ell} = \frac{\Gamma(\ell/2)}{\Gamma(\ell)} - 4\frac{\Gamma(\ell/2 + 1)}{\Gamma(\ell + 2)}. \] (5.19)

We then find

\[ Z^{(1)}_{\ell} = \frac{\ell}{48\pi} (2\ell^2 + 1) \left[ \frac{\Gamma^2(\ell/2 + 1)}{4\Gamma'(\ell + 2)} - \frac{\Gamma^2(\ell/2 + 1)}{2\Gamma(\ell + 2)} \right] - \frac{\ell^2}{16\pi} \frac{\Gamma^2(\ell/2 + 1)}{\Gamma(\ell + 2)}. \] (5.20)

From (5.20) one can compute \( J_1(z) \) in closed form. Let us introduce the function

\[ f(z) = \frac{\zeta}{3F_2} \left[ 1, 1, 1; \frac{3}{2}, \frac{3}{2}; \frac{1}{16} \right] - \frac{z^2}{24} 3F_2 \left[ 1, 1, 2; \frac{5}{2}, \frac{5}{2}; \frac{1}{16} \right] \]

\[ + \frac{1}{z} \left\{ -2\pi E \left( \frac{z}{2} \right) - z + \pi^2 \right\} \] (5.21)

where \( E(k) \) is the complete elliptic integral of the second kind with modulus \( k \). Then, one finds

\[ J_1(\mu) = \frac{1}{24} \left\{ f(z) - \left( z \frac{\partial}{\partial z} \right) f(z) \right\}. \] (5.22)

The asymptotic expansion of the above function at large \( \mu \) is given by

\[ f(z) - \left( z \frac{\partial}{\partial z} \right) f(z) = \mu - 2 + O(\mu^2 e^{-2\mu}). \] (5.23)

Therefore, we find, at next-to-leading order in \( k \), the following expression for the grand canonical potential of ABJM theory:

\[ J_{ABJM}(\mu) \approx \frac{2\mu^3}{3k\pi^2} + \mu \left( \frac{1}{3k} + \frac{k}{24} \right) + \frac{2\xi(3)}{\pi^2 k} - \frac{k}{12} + O(\mu^2 e^{-2\mu}). \] (5.24)

Notice that the non-perturbative corrections in \( \mu \) to (5.23) involve only even powers of \( z \). This is consistent with their interpretation as membrane instantons.
5.2. General structure of quantum corrections

As we mentioned above, we can compute the quantum corrections to $J(\mu)$ either by working out the corrections to the $Z_\ell$ integrals, or by working out the corrections to the function $n(E)$. In order to understand the general structure of these corrections for a Fermi gas, the second point of view is more convenient. In this section we will analyze this general structure in detail and we will make a precise connection between the structure of $n(E)$ and the expected Airy function behavior.

First of all, we have to understand more precisely the relationship between the structure of $n(E)$ and the structure of $J(\mu)$. Let us write the density function $n(E)$ in the form

$$n(E) = CE^2 + n_0 + n_{np}(E),$$  \hspace{1cm} (5.25)

where the last term has the following asymptotics at infinity:

$$n_{np}(E) = \mathcal{O}(E^{-E}), \quad E \to \infty.$$  \hspace{1cm} (5.26)

We know from (4.40) that this is indeed the case at leading order in $k$ for ABJM theory and in section 5.3 we will show that quantum corrections do not spoil this behavior. Notice that, since all eigenvalues of our Hamiltonian are positive, we must have

$$n(0) = 0,$$  \hspace{1cm} (5.27)

and therefore

$$n_{np}(0) = -n_0.$$  \hspace{1cm} (5.28)

If we now plug (5.25) in (4.6) we find

$$J(\mu) = \int_0^\infty dE n'(E) \log(1 + ze^{-E}) = -2C\text{Li}_3(-z) + \mu \int_0^\infty dE n'_{np}(E)$$

$$- \int_0^\infty dE n'_{np}(E)E + \int_0^\infty dE n'_{np}(E) \log(1 + e^E/z).$$  \hspace{1cm} (5.29)

The second term gives

$$\int_0^\infty dE n'_{np}(E) = -n_{np}(0) = n_0,$$  \hspace{1cm} (5.30)

where we used that (5.28). The last term can be calculated as

$$\int_0^\infty dE n'_{np}(E) \log(1 + e^E/z) = n_0 \log(1 + 1/z) - \int_0^\infty dE \frac{n_{np}(E)}{1 + ze^{-E}},$$  \hspace{1cm} (5.31)

and both terms are non-perturbative in $\mu$. Indeed

$$\int_0^\infty dE \frac{n_{np}(E)}{1 + ze^{-E}} \sim \int_0^\infty dE \frac{Ee^{-E}}{1 + ze^{-E}} = \mathcal{O}(e^{-\mu}).$$  \hspace{1cm} (5.32)

Then, by using the standard asymptotics of the trilogarithm

$$\text{Li}_3(-z) = -\frac{\mu^3}{6} - \frac{\pi^2}{6} \mu + \mathcal{O}(e^{-\mu}),$$  \hspace{1cm} (5.33)
we deduce the following asymptotic expansion of $J(\mu)$ for large $\mu$:

$$J(\mu) = \frac{C}{3} \mu^3 + B\mu + A + J_{np}(\mu),$$

(5.34)

where

$$B = n_0 + \frac{\pi^2 C}{3}, \quad A = - \text{Tr} \hat{H} \equiv - \int_0^\infty dE E n'_{np}(E),$$

(5.35)

and

$$J_{np}(\mu) = O(\mu e^{-\mu}).$$

(5.36)

Notice that $A$ is a non-trivial function of $k$, but it does not depend on $\mu$. If we now plug this in (3.14), we find immediately

$$Z(N) = C^{-1/3} e^{A} \text{Ai}[C^{-1/3}(N - B)] + Z_{np}(N),$$

(5.37)

where the last term is non-perturbative in $N$.

We then see that, if we are able to derive the structural results (5.25) and (5.26) for the density of states of a given theory, the conjecture 1.1 for the M-theory expansion is proved. In fact, so far we have not specified in which regime we are working in $k$. In practice, we have to work in an expansion in $k$ around $k = 0$. However, we expect that $C$ will only get contributions at leading order in $k$ (i.e. the strict semiclassical limit), and that $B$ will be only corrected at the next-to-leading order in $k$. We will now verify this in ABJM theory. In contrast, the $\mu$-independent term $A$ gets corrected at all orders in $k$.

5.3. Quantum corrections in ABJM theory

We now study the general structure of quantum corrections in ABJM theory by using the strategy explained above, i.e. by looking at the number of eigenvalues $n(E)$. Our goal is to show that $n(E)$ has the structure (5.25). This involves a somewhat detailed argument. Since not every reader might go through it, we want to emphasize that the physics behind this argument is very simple. The WKB expansion of the density of eigenvalues of a quantum system is, in fact, an expansion in

$$\left(\hbar \frac{d}{dE}\right)^2.$$  

(5.38)

Therefore, if the leading order term in $n(E)$ is of the form $CE^2$, the first quantum correction gives the constant term in (5.25), and further terms in the WKB expansion do not correct the polynomial part of $n(E)$. They can only give exponentially small corrections in $E$. In the rest of this section, we will verify that this qualitative argument is actually correct in the case of the one-body problem appearing in ABJM theory.

Our starting point in the study of quantum corrections in ABJM theory is (5.8). As we know, there are two sources of $\hbar$ corrections in this formula. One is the quantum-corrected Hamiltonian and the other are the terms $\mathcal{G}$, appearing in the generalized Wigner–Kirkwood expansion. We will consider first the quantum corrections coming from $H_W$, i.e. from the first term in (5.8). Since we have a symmetry $q \rightarrow -q$ and $p \rightarrow -p$ in the problem, we can restrict ourselves to the case $q \geq 0$ and $p \geq 0$. We want to solve the equation

$$H_W(q, p) = E$$

(5.39)

doi:10.1088/1742-5468/2012/03/P03001 29
in the limit $E \to \infty$. This defines a 'quantum curve' or 'quantum Fermi surface', including explicit $\hbar$ corrections. At leading order in $E$ the curve is given by (4.22) and the corresponding domain (in the positive quadrant) has volume

$$\text{Vol}_0(E) = 2E^2.$$  

One crucial ingredient in what follows is the fact that the function $U(q)$ and its derivatives have the following asymptotics as $q \gg 1$:

$$U(q) = \log 2 \cosh \frac{q}{2} = \frac{q}{2} + \sum_{k \geq 1} \frac{(-1)^{k+1}}{k} e^{-kq},$$

$$U'(q) = \frac{1}{2} \tanh \frac{q}{2} = \frac{1}{2} + \sum_{k \geq 1} (-1)^k e^{-kq},$$

$$U''(q) = \frac{1}{4 \cosh^2 q/2} = \sum_{k \geq 1} k(-1)^{k+1} e^{-kq}.$$  

The same results hold for $T(p)$. Notice that, if we take a large enough number of derivatives of these functions, they become exponentially suppressed at infinity. This will eventually be the source of the simplifications at large $E$.

Let us now consider the point $(q_*, p_*)$ in the curve (5.39), where

$$p_* = E.$$  

It is easy to see from the explicit form of $H_W$ that

$$q_* = E + \mathcal{O}(e^{-E})$$  

where the exponentially small corrections in $E$ are themselves power series in $\hbar^2$. This point divides the curve (5.39) into two segments and defines two regions for the fully corrected volume, as shown in figure 4. Region I is defined as the region under the quantum curve with $p \geq p_*$, while region II is defined by $q \geq q_*$. We have

$$\text{Vol}(E) = 4\text{Vol}_I(E) + 4\text{Vol}_II(E),$$  

where

$$\text{Vol}_I(E) = \int_0^{q_*(E)} p(E, q) \, dq, \quad \text{Vol}_II(E) = \int_0^{p_*(E)} q(E, p) \, dp - p_*q_*.$$  

and $p(E, q)$ and $q(E, p)$ are local solutions of $H_W(q, p) = E$. 

Figure 4. The regions I (left) and II (right) under the quantum curve $H_W(q, p) = E$ in the positive quadrant. The diagonal dashed line is the polygonal curve (4.22).
Let us first consider the curve bounding region I. Along this curve, \( p(q, E) \geq E \), therefore exponential terms in \( p \) in \( H_W \) are bounded by exponential terms in \( E \). We can then write

\[
T(p) = \frac{p}{2} + \mathcal{O}(e^{-E}), \quad T'(p) = \frac{1}{2} + \mathcal{O}(e^{-E}),
\]

and

\[
T^{(n)}(p) = \mathcal{O}(e^{-E}), \quad n \geq 2.
\]

(5.46) (5.47)

In the quantum corrections to the function \( H_W \) we will have terms of the form \( (T^{(k)}(p))^n \), with \( k \geq 1 \). Due to (5.46) and (5.47), and neglecting exponentially small corrections of the form \( \mathcal{O}(e^{-E}) \), we should keep only the terms \( (T'(p))^n \) with \( n \geq 1 \) (like the third term in the second line of (3.44)). But these terms always multiply terms of the form \( U^{(2n)}(q) \). We conclude that, on the curve bounding region I,

\[
H_W = \frac{p}{2} + U(q) - \frac{\hbar^2}{48} U''(q) + \frac{1}{2} \sum_{n>1} \hbar^{2n} c_n U^{(2n)}(q) + \mathcal{O}(e^{-E}).
\]

(5.48)

The second term comes from the corrections to the curve and it is given by

\[
\Delta p(E, q) = q - 2U(q) + \frac{\hbar^2}{24} U''(q) - \sum_{n>1} \hbar^{2n} c_n U^{(2n)}(q) + \mathcal{O}(e^{-E}).
\]

(5.50)

We calculate the volume of region I as follows:

\[
\text{Vol}_I = \text{Vol}_I^0 + \Delta \text{Vol}_I.
\]

(5.51)

The first term comes from the polygonal limit of the curve:

\[
\text{Vol}_I^0(E) = \int_0^{q_s(E)} (2E - q) \, dq = 2Eq_s(E) - \frac{q_s^2(E)}{2}.
\]

(5.52)

The second term comes from the corrections to the curve and it is given by

\[
\Delta \text{Vol}_I(E) = \int_0^{q_s(E)} \Delta p(E, q) \, dq - 2 \int_0^{q_s(E)} \left( U(q) - \frac{q}{2} \right) \, dq + \frac{\hbar^2}{24} \int_0^{q_s(E)} U''(q) \, dq - \sum_{n>1} \hbar^{2n} c_n \int_0^{q_s(E)} U^{(2n)}(q) \, dq + \mathcal{O}(Ee^{-E})
\]

\[
= -2 \int_0^{q_s(E)} \left( U(q) - \frac{q}{2} \right) \, dq + \frac{\hbar^2}{24} \int_0^\infty U''(q) \, dq - \sum_{n>1} \hbar^{2n} c_n \int_0^\infty U^{(2n)}(q) + \mathcal{O}(Ee^{-E})
\]

\[
= -\frac{\pi^2}{6} + \frac{\hbar^2}{48} + \mathcal{O}(Ee^{-E}).
\]

(5.53)
In the last calculation we used that, up to non-perturbative terms in $E$, we can extend the integration region to infinity, and also that
\[
\int_0^\infty U^{(2n)}(q) \, dq = U^{(2n-1)}(\infty) - U^{(2n-1)}(0) = 0 \quad \text{for} \quad n > 1. \tag{5.54}
\]
A similar calculation can be done for region II. We obtain, from the polygonal approximation of the curve,
\[
\text{Vol}_0^0(E) = 2E p_\ast(E) - \frac{p_\ast^2(E)}{2} - p_\ast(E) q_\ast(E), \tag{5.55}
\]
while the corrections give
\[
\Delta \text{Vol}_0^0(E) = -\frac{\pi^2}{6} - \frac{\hbar^2}{96} + O(E e^{-E}). \tag{5.56}
\]
Using that
\[
p_\ast(E) + q_\ast(E) = 2E + O(e^{-E}) \tag{5.57}
\]
we finally get
\[
\text{Vol}(E) = 8E^2 - \frac{4\pi^2}{3} + \frac{\hbar^2}{24} + O(E e^{-E}). \tag{5.58}
\]
We now consider the contribution from the quantum corrections to the density. In fact, these terms only give non-perturbative corrections in $E$. Using that
\[
\delta(E - H_W(q, p)) = \delta(p - p(E, q)) \left/ \frac{\partial H_W(q, p)}{\partial p} \right|_{p=p(E, q)} = \delta(q - q(E, p)) \left/ \frac{\partial H_W(q, p)}{\partial q} \right|_{p=p(E, q)} \tag{5.59}
\]
one can always decompose an integral over the phase space as a sum of one-dimensional integrals in regions I and II, as in (5.44). For region I one can use again the expression (5.48) and the properties (5.46) and (5.47). The only non-trivial term which gives an $\hbar^2$ correction comes from $\mathcal{G}_3$ and gives
\[
\frac{\hbar^2}{24} \frac{\partial^2}{\partial E^2} \int_0^{q_\ast(E)} dq \, \frac{\partial H_W(q, p)}{\partial p} \frac{\partial^2 H_W(q, p)}{\partial q^2} \bigg|_{p=p(E, q)} = \frac{\hbar^2}{24} \frac{\partial^2}{\partial E^2} \int_0^{q_\ast(E)} dq \left( \sum_{n \geq 0} \hbar^{2n} c_n U^{(2n+2)}(q) + O(e^{-E}) \right) = O(E e^{-E}). \tag{5.60}
\]
For higher-order corrections everything that contains a term with
\[
\frac{\partial^r H_W(q, p)}{\partial p^r}, \quad r > 1, \tag{5.61}
\]
or with
\[
\frac{\partial^2 H_W(q, p)}{\partial p \partial q} \tag{5.62}
\]
is of order $e^{-E}$. Since the derivatives $\partial_p$ and $\partial_q$ always come in pairs, the only terms possibly contributing are of the form
\[
\prod_i \left( \frac{\partial H_W(q, p)}{\partial p} \right)^{n_i} \frac{\partial^n H_W(q, p)}{\partial q^{n_i}} = \prod_i \frac{\partial^{n_i} H_W(q, p)}{\partial q^{n_i}} + O(e^{-E}) \tag{5.63}
\]
where $n_i \geq 2, \forall i$. After integrating and applying $\partial^r / \partial E^r$ this gives a correction of order $\mathcal{O}(e^{-E})$ by the same reason.

We conclude that, to all orders in the $\hbar$ expansion,

$$n(E) = \frac{\text{Vol}(E)}{2\pi \hbar} + \mathcal{O}(e^{-E}) = \frac{2E^2}{\pi k} - \frac{1}{3k} + \frac{k}{24} + \mathcal{O}(e^{-E}).$$

(5.64)

Therefore, by using (5.34) and (5.35) we find the expression

$$J_{\text{ABJM}}(\mu) = \frac{2g^3}{3k\pi^2} + \mu \left( \frac{1}{3k} + \frac{k}{24} \right) + A(k) + J_{\text{np}}(\mu)$$

(5.65)

where

$$J_{\text{np}}(\mu) = \sum_{\ell,n=1}^{\infty} \left( a_{\ell,n} \mu^2 + b_{\ell,n} \mu + c_{\ell,n} \right) k^{2n-3} e^{-2\ell \mu}.$$  

(5.66)

It is not manifest from the above results that this series involves only even powers of $z^{-1}$, but we have verified it to be the case for the first three orders in $k$, and we believe it is a general feature. Finally, it follows from (5.64) and (5.37) that

$$Z_{\text{ABJM}}(N) = C^{-1/3} e^{A(k)} \text{Ai} \left[ C^{-1/3} \left( N - \frac{1}{3k} - \frac{k}{24} \right) \right] + Z_{\text{np}}(N),$$

(5.67)

where $C$ is given in (2.15) and $Z_{\text{np}}(N)$ are exponentially suppressed corrections at large $N$. This concludes our derivation of the Airy behavior for ABJM theory. The function $A(k)$ can, in principle, be determined, order by order in $k$, by computing the $Z^{(n)}_\ell$, resumming the resulting series and expanding at $\mu = \infty$, as we did in sections 4.3 and 5.1. One obtains

$$A(k) = \frac{2\zeta(3)}{\pi^2 k} - \frac{k}{12} + \frac{\pi^2 k^3}{4320} + \mathcal{O}(k^5).$$

(5.68)

A sketch of the computation leading to the third term of this expansion can be found in the appendix. In principle, one can also compute $A(k)$ by using the representation (5.35).

We have identified the exponentially suppressed corrections as coming from membrane instantons, which are invisible in the ’t Hooft expansion. The function $A(k)$ appearing in (5.67) encodes also extra information on the M-theory expansion of the partition function which is available in the Fermi gas approach but not in the ’t Hooft expansion. This indicates that $A(k)$ should have an essential singularity at $k = \infty$; otherwise it would have a non-trivial power series expansion in $1/k$ at $k \to \infty$, which would also contribute to the ’t Hooft expansion. The most natural possibility is that $A(k)$ encodes effects of order $\mathcal{O}(e^{-k}) \sim \mathcal{O}(e^{-1/g^3})$,

$$A(k) \sim \mathcal{O}(e^{-1/g^3}),$$

(5.69)

i.e. that $A(k)$ gives the contribution from D0-branes. Notice that the second and third coefficients in (5.68) are given by

$$-\frac{B_{2g}}{g(2g-1)(2g)!} \pi^{2g-2}$$

(5.70)

for $g = 1, 2$. These are the coefficients of the power series expansion in $k$ of

$$-\frac{2}{\pi} \int_0^{\pi k} \frac{d\xi}{\xi^2} \log \left[ \frac{\sinh(\xi/2)}{\xi/2} \right].$$

(5.71)

This gives indeed corrections of the form (5.69). It would be interesting to verify that the above function resums the small $k$ expansion of $A(k)$. 

\textbf{J. Stat. Mech. (2012) P03001}
Figure 5. The Riemann surface of $H_{cl}(p, q) = E$ for ABJM theory for large $E$. The four interior tubes form the limiting polygon of the Fermi surface.

5.4. Quantum-mechanical instantons as worldsheet instantons

One obvious question that one can ask at this point is the following: where are the worldsheet instantons (2.6) that one finds perturbatively in $g_s$ in the `t Hooft expansion? We now give some preliminary evidence that worldsheet instantons correspond to the quantum-mechanical instantons of the Hamiltonian $H_W$.

So far our focus has been in the perturbative corrections in $\hbar$, but one should expect generically non-perturbative corrections due to instantons, of order $\exp(-1/\hbar)$. To understand these quantum-mechanical instantons in our problem, with a non-conventional Hamiltonian, we need a general, geometric approach to non-perturbative WKB expansions, like the one proposed in [50,51]. In this approach, instanton contributions are obtained by looking at the complexified curve

$$H(q, p) = E$$

where $H(q, p)$ is the Hamiltonian of the model. Perturbative WKB expansions are associated with periods of the above curve around ‘A-type’ cycles, while non-perturbative corrections to the WKB method are associated with ‘B-type’ cycles. In the case of ABJM theory, the complexified curve is identical to the spectral curve (4.44), after an appropriate choice of the variables. Its Riemann surface looks as shown in figure 5. Let us introduce canonical coordinates $Q, P$ related to the $q, p$ coordinates as

$$Q = q, \quad P = p + q.$$  

This preserves the symplectic form. The coordinate $P$ is chosen so that it has no monodromy along the contour $B$. Then in the large $E$ limit

$$n(E) \approx \frac{1}{2\pi\hbar} \oint_A P \, dq \approx \frac{1}{2\pi\hbar} \text{Vol}\{(q, p) : |p| + |q| < 2E\} = \frac{4E^2}{\pi\hbar}. \quad (5.74)$$
The instanton contribution is of order
\[ \exp \left( \frac{i}{\hbar} \oint_B P \, dQ \right), \tag{5.75} \]
where in the large \( E \) limit
\[ \oint_B P \, dQ = 2E \cdot 4\pi i + \mathcal{O}(e^{-cE}). \tag{5.76} \]
Here we used that, in the interior of the upper-right tube, \( P = p + q = 2E + \mathcal{O}(e^{-cE}) \) for some constant \( c \) and that the monodromy of \( Q \) around the tube is \( 4\pi i \). The above period can be computed exactly with the results of [8] since the behavior (5.76) fixes it completely:
\[
\oint_B P \, dQ = -2ie^E \pi \gamma F_2 \left( \frac{1}{2}, \frac{1}{2}, 1, \frac{3}{2}; \frac{e^{2E}}{16} \right) - \frac{e^E}{\pi} C_{2,3} \left( \frac{e^{2E}}{16} \right) \left( \frac{1}{2}, \frac{1}{2}, 1, 0, 0, -\frac{1}{2} \right) + 4\pi^2
= 8\pi E + \mathcal{O}(e^{-2E}). \tag{5.77} \]
In fact, after the identification (4.45), this period is equal to \(-4A_s\), where \( A_s \) is the strong coupling instanton action computed in [8]. For large energy, (5.77) gives a contribution to the density of states of order
\[ \exp \left( -\frac{4E}{k} \right) \tag{5.78} \]
which becomes a contribution
\[ \exp \left[ -\frac{4\mu}{k} \right] \tag{5.79} \]
to the grand canonical potential and a contribution
\[ \sim \exp \left[ -2\pi \sqrt{2N/k} \right] \tag{5.80} \]
to the canonical free energy. This is precisely the weight of a worldsheet instanton (2.6) in ABJM theory.

Quantum-mechanical instantons are, of course, invisible in the perturbative \( \hbar \) expansion of \( H_W \) and in the Wigner–Kirkwood expansion, but they appear in the ’t Hooft expansion. In fact, the ’t Hooft expansion of the canonical free energy
\[ F(\lambda, k) = \sum_{g \geq 0} k^{2-2g} F_g(\lambda) \tag{5.81} \]
leads to a genus expansion of the grand canonical potential of the form [23]
\[ J_{tH \! ooft}(\mu, k) = \sum_{g \geq 0} k^{2-2g} J_g(\mu/k). \tag{5.82} \]
Notice that, in the Fermi gas approach, only the perturbative part in \( \mu \) of \( J(\mu) \) can be written in this form (5.82). The membrane instanton contributions and the function \( A(k) \) do not have the right functional dependence in \( \mu/k \) to fit into the ’t Hooft expansion, while the weight associated with a quantum-mechanical instanton (5.79) is again of the right form. In the case of ABJM theory, we see from (5.24) that the Fermi gas approach

doi:10.1088/1742-5468/2012/03/P03001
ABJM theory as a Fermi gas

gives
\begin{align}
  J_0(\zeta) &= \frac{2\zeta^3}{3\pi^2} + \frac{\zeta}{24} + \mathcal{O}(e^{-4\zeta}), \\
  J_1(\zeta) &= \frac{\zeta}{3} + \mathcal{O}(e^{-4\zeta}), \\
  J_g(\zeta) &= \mathcal{O}(e^{-4\zeta}), \quad g \geq 2,
\end{align}

where \( \zeta = \mu/k \). From the point of view of the topological string, it follows from (2.30) that the variable \( \zeta \) is essentially the period \( T \) at large radius, and a perturbative Fermi gas approach makes it possible to recover the leading perturbative genus zero and genus one free energies of the topological string given in (2.25).

Finally, we should mention that there is an extra source of worldsheet instanton-like corrections. In general, the exact representation \((3.13)\) and the saddle-point integral \((3.14)\) are only equivalent up to exponentially small corrections in \( N \). Since we are taking into account such corrections, we have to be more careful here. The expression \((3.13)\) is equivalent to
\begin{equation}
  Z(N) = \frac{1}{2\pi i} \int_{\mu_*-i\pi}^{\mu_*+i\pi} d\mu \exp[J(\mu) - \mu N],
\end{equation}

where the integration contour is parallel to the imaginary axis and \( \mu_* \) is arbitrary. To apply the saddle-point method, one chooses for \( \mu_* \) the saddle-point of the exponent and then extends the integration contour to infinity along the imaginary axis (this is what gives the Airy function behavior we have found many times in this paper). As is well known, it is in this last step of extending the integration contour that one introduces exponentially small errors in \( N \). A rough estimate of these errors can be done as follows. The saddle-point expansion involves integrating a Gaussian of the form
\begin{equation}
  \exp[\frac{1}{2}(\mu - \mu_*)^2 J''(\mu_*)].
\end{equation}
The error in going to \((3.14)\) can then be estimated by evaluating this Gaussian at the true endpoints in \((5.84)\). This gives, by using the leading term in \((5.24)\),
\begin{equation}
  \sim \exp[-2\mu_* / k] \quad (5.86)
\end{equation}
which is the square root of \((5.79)\). Therefore, these types of corrections should also be taken into account when trying to extract information about worldsheet instantons.

6. More general Chern–Simons-matter theories

In this section we consider in detail more general CSM theories. We first study the thermodynamic limit of necklace quivers and derive a general formula for the large \( N \) limit of their free energy which agrees with the result obtained in [17,18] by analyzing the matrix model. Then we extend the considerations of section 5.3 to the general necklace CSM theories considered in section 3.2. For technical reasons we restrict ourselves to theories whose Hamiltonian is Hermitian, i.e. whose free energy is real, and we show that, with that assumption, the Airy behavior of the resummed \( 1/N \) expansion found in [9] is indeed generic. These general considerations are then illustrated in detail in the case of ABJM theory (i.e. the two-node theory) with fundamental matter. Finally, we consider the massive theories of [52] and we derive the \( N^{5/3} \) behavior found in [53,14] with our techniques.

doi:10.1088/1742-5468/2012/03/P03001
6.1. Thermodynamic limit for general necklace quivers

In this section we study the general necklace quiver considered in section 3.2. From (3.55) it follows that, for large energy, the Fermi surface is defined by the polygonal equation

$$\sum_{j=1}^r \left| p - \left( \sum_{i=1}^{j-1} n_i \right) q \right| + \left( \sum_{j=1}^r \frac{N_{f_j}}{k} \right) |q| = 2E. \quad (6.1)$$

As an example, we show in figure 6 the classical Fermi surface (6.1) at small and large energies, for a three-node quiver with $n_a = (1, 3, -4)$. By the, by now familiar, argument of the previous sections, the number of eigenstates is given by the semiclassical formula (4.13) applied to the domain bounded by (6.1). One finds

$$n(E) \approx CE^2, \quad (6.2)$$

where the constant $C$ is given by

$$\pi^2 C = \text{Vol} \left\{ (x, y) : \sum_{j=1}^r \left| y - \left( \sum_{i=1}^{j-1} k_i \right) x \right| + \left( \sum_{j=1}^r N_{f_j} \right) |x| < 1 \right\}. \quad (6.3)$$

and the variables $y, x$ differ from $p, q$ in (6.1) by rescaling. Once this constant has been determined, the large $N$ asymptotics of the free energy is given by (4.11)

$$F(N) \approx -\frac{2}{3} C^{-1/2} N^{3/2}. \quad (6.4)$$

In order to compute $C$, we notice that the right-hand side of (6.3) is the volume of a convex polygon which can be easily calculated. Suppose for simplicity that $N_{f_j} = 0$. Let us introduce new parameters $c_j$, related to $k_i$ in the following way:

$$c_{\sigma(j)} = c + \sum_{i=1}^{j-1} k_i \quad (6.5)$$

where $c$ is an auxiliary constant and $\sigma$ is a permutation chosen so that $c_i \leq c_{i+1}, \forall i$. Then

$$\pi^2 C = \text{Vol}\{ (x, y) : \sum_{j=1}^r |y - c_j x| < 1 \}. \quad (6.6)$$
Let us note that the $c_j$ differ by a permutation from the parameters $q_a$ introduced in [10] (where they were defined in such a way that $k_a = q_{a+1} - q_a$). Notice also that the expression (6.6) is explicitly invariant under permutations of the $c_j$. The inequality $\sum_{j=1}^{r} |y - c_j x| < 1$ defines a convex hull of $2r$ points $(\pm x, \pm y)$ so that

$$y_s = c_s x_s, \quad \sum_{j=1}^{r} |y_s - c_j x_s| = 1.$$

(6.7)

One finds

$$x_s = \frac{1}{\sum_{j=1}^{r} |c_s - c_j|}, \quad y_s = \frac{c_s}{\sum_{j=1}^{r} |c_s - c_j|}.$$

(6.8)

Then one can use the standard formula for the area of a convex hull to find

$$\pi^2 C = \sum_{s=1}^{r} \frac{|c_{s+1} - c_s|}{(\sum_{j=1}^{r} |c_{s+1} - c_j|)(\sum_{j=1}^{r} |c_s - c_j|)}$$

(6.9)

where as usual we use the convention $c_{r+1} = c_1$. Let us illustrate this formula by applying it to necklaces with three and four nodes. For the necklace with three nodes $(k_1, k_2, k_3)$ we can assume, without loss of generality, that

$$|c_1 - c_2| = |k_3|, \quad |c_2 - c_3| = |k_1|, \quad |c_1 - c_3| = |k_2|.$$

(6.10)

Then

$$\frac{\pi^2 C}{2} = \frac{|k_1||k_2| + |k_2||k_3| + |k_3||k_1|}{(|k_1| + |k_2|)(|k_2| + |k_3|)(|k_3| + |k_1|).}$$

(6.11)

For the quiver with four nodes, let us assume without loss of generality that $\sum_{i=1}^{4} c_i = 0$. Then an easy computation gives

$$\frac{\pi^2 C}{2} = \frac{1}{32} \left( \frac{1}{c_1} - \frac{1}{c_4} + 12 \frac{1}{c_3 + c_4} + 4 \frac{c_1 + c_3}{(c_3 + c_4)^2} \right).$$

(6.12)

These formulae for the three- and four-node quivers agree with the results first found in [10] (for the four-node quiver, their formula is obtained by setting $c_1 = q_3$, $c_2 = q_1$, $c_3 = q_2$ and $c_4 = q_4$). In fact, the above general result for the free energy of these CSM theories, involving the area of the polygon (6.3), has been derived in this form in [17, 18] by refining the analysis of the matrix model done in [10] (where a different, but equivalent, general formula for the free energy was proposed). This class of CSM theories is dual to M-theory on $\text{AdS}_4 \times X_7$, where $X_7$ is an appropriate tri-Sasaki Einstein space [39]. Therefore, the coefficient $C$ should be proportional to the volume of the $X_7$ manifold and one should have

$$\frac{\text{Vol}(X_7)}{\text{Vol}(S^7)} = \frac{\pi^2 C}{2} = \frac{1}{2} \text{Vol} \left\{ (x, y) : \sum_{j=1}^{p} y - \left( \sum_{i=1}^{j-1} k_i \right) x + \left( \sum_{j=1}^{p} N_f \right) |x| < 1 \right\}.$$

(6.13)

This is indeed the case, as was proved in [17].

We then see that the Fermi gas approach allows us to rederive the result for the large $N$ energy obtained in [17], but in a simpler way. The polygon appearing in the matrix model analysis of [17] has here a very simple interpretation: it is the large energy limit of the Fermi surface for the ideal Fermi gas.
6.2. Airy function behavior for a class of CSM theories

We now extend the considerations of section 5.3 to more general necklace quivers with matter. In section 6.3 we apply the general considerations developed here to the case of ABJM theory with matter.

Let us assume that the Wigner transform of the density matrix can be written in the form

$$
\rho_W(q,p) \equiv \exp\{ -H_W \} = e^{-\Phi_1(Q_{R_1})} \star e^{-\Phi_2(Q_{R_2})} \star \cdots \star e^{-\Phi_m(Q_{R_m})},
$$

(6.14)

where

$$
Q_R = a_R q + b_R p
$$

(6.15)

for suitable $a_R$ and $b_R$, and the different $Q_R$ are given by linearly independent combinations of $q, p$. We will also suppose that the functions $\Phi_i$ are real valued, even, and that

$$
\Phi_i(Q) = \gamma_i |Q| + O(e^{-c|Q|}), \quad Q \to \infty, \quad \gamma_i > 0.
$$

(6.16)

These assumptions are obviously true for the general necklace quivers considered in section 3.2. In addition, we will suppose that $H_W(q,p)$ is real. This corresponds to the case when the quantum operator $\hat{H}$ is Hermitian. It should be possible to treat the general case, when $\hat{H}$ has complex eigenvalues, with similar techniques, but we will not do it here.

As usual, the leading contribution to the number of states is given by the volume of a polygon:

$$
n(E) \approx \frac{1}{2\pi \hbar} \text{Vol} \left\{ (q,p) : \sum_{i=1}^{m} \gamma_i |a_{R_i} q + b_{R_i} p| < E \right\} = C E^2.
$$

(6.17)

---

Figure 7. The black thick line depicts the Fermi surface (6.18). The green thin line depicts the limiting polygon. The red thick dashes mark the boundaries of the patches $U_R$. 

$^3$ In what follows, the constant $c > 0$ may have different values in different formulae.
Let
\[ C_E = \{ (q, p) : H_W(p, q) = E \} \] (6.18)
be the real curve describing the Fermi surface. One can always decompose \( C_E \) into patches \( \mathcal{U}_R, \mathcal{U}'_R \) so that both \( \mathcal{U}_R \) and \( \mathcal{U}'_R \) contain one point, where \( Q_R = 0 \), \( \mathcal{U}'_R \) is related to \( \mathcal{U}_R \) by reflection through the center of the polygon and
\[ \sum_{i=1}^{m} \gamma_i |a_{R_i}q + b_{R_i}p|\bigg|_{\partial \mathcal{U}_R, \partial \mathcal{U}'_R} = E + \mathcal{O}(e^{-cE}). \] (6.19)

In figure 7 we depict the general structure of such decomposition. In the case of ABJM theory considered in section 5.3, the boundaries of regions I and II lying on the curve \( C_E \) are halves of the patches \( \mathcal{U}_1 \) and \( \mathcal{U}_2 \). A particular example of such a decomposition of the Fermi surface in regions is shown in figure 10, in the case of ABJM theory with fundamental matter. We will now argue that, for each patch \( \mathcal{U}_R \), the structure of corrections is essentially the same as in the ABJM case.

One can always choose
\[ P_R = c_R p + d_R q \] (6.20)
so that
\[ dQ_R \wedge dP_R = dq \wedge dp \] (6.21)
and such that, in the domain \( \mathcal{U}_R \), the Hamiltonian can be written as follows:
\[ H_W(q, p) = \beta_R P_R + \sum_{i| R_i = R} \Phi_i(Q_R) + \sum_{r>0} \sum_{i| R_i = R} \hbar^2 c_{r,i}^R \phi_{i}^{(2r)}(Q_R) + \mathcal{O}(e^{-cE}) \] (6.22)
where \( \mathcal{O}(e^{-cE}) \) denotes an estimate which is uniform in \( \mathcal{U}_R \). Without loss of generality one can assume that \( \beta_R > 0 \). Then in the domain \( \mathcal{U}_R \) the solution to \( H_W^{(R)}(P_R, Q_R) \equiv H_W(p, q) = E \) can be written as
\[ P_R(E, Q_R) = \frac{1}{\beta_R} \left( E - \sum_{i| R_i = R} \gamma_i |Q_R| \right) + \Delta P_R(E, Q_R). \] (6.23)

In this equation
\[ \Delta P_R(E, Q_R) = \Delta_P P_R(Q_R) + \mathcal{O}(e^{-cE}), \] (6.24)
where \( \Delta_P \) denotes the perturbative part of the correction. It is given by
\[ \Delta_P P_R(Q_R) = -\frac{1}{\beta_R} \left( \sum_{i| R_i = R} (\Phi_i(Q_R) - \gamma_i |Q_R|) + \sum_{r>0} \sum_{i| R_i = R} \hbar^2 c_{r,i}^R \phi_{i}^{(2r)}(Q_R) \right), \] (6.25)
and satisfies the property
\[ \Delta_P P_R(Q_R) = \mathcal{O}(e^{-c|Q_R|}), \quad Q_R \to \infty \] (6.26)
The property (6.19) implies that
\[
\text{Vol} \{ H_W(q, p) < E \} = \text{Vol} \left\{ \sum_{i=1}^{m} \gamma_i |Q_i| < E \right\} + 2 \sum_{R} \Delta \text{Vol}_R(E) + \mathcal{O}(e^{-cE})
\] (6.27)

where
\[
\Delta \text{Vol}_R(E) = \int_{\Omega_R} \Delta P_R(E, Q_R) \, dQ_R.
\] (6.28)

From (6.24) it follows that
\[
\Delta \text{Vol}_R(E) = \int_{\Omega_R} \Delta p_R(Q_R) \, dQ_R + \mathcal{O}(e^{-cE}).
\] (6.29)

By using (6.26), we can extend the integration region to infinity, up to non-perturbative corrections, and we obtain
\[
\Delta \text{Vol}_R(E) = \int_{-\infty}^{\infty} \Delta p_R(Q_R) \, dQ_R + \mathcal{O}(e^{-cE}).
\] (6.30)

Let us denote
\[
\Delta_p \text{Vol}_R \equiv \int_{-\infty}^{\infty} \Delta p_R(Q_R) \, dQ_R = -\frac{1}{\beta_R} \int_{-\infty}^{\infty} \sum_{i|R_i=R} (\Phi_i(Q_R) - \gamma_i |Q_i|) \, dQ_R
\]
\[
- \frac{2\hbar^2}{\pi \beta_R} \sum_{i|R_i=R} c_{1,i}^R \gamma_i.
\] (6.31)

Similarly to what happened in ABJM theory, there are no perturbative corrections to \(n(E)\) from higher terms of the Wigner–Kirkwood expansion. Therefore we obtain
\[
n(E) = CE^2 + n_0 + \mathcal{O}(e^{-cE})
\] (6.32)

with
\[
n_0 = \frac{1}{\pi \hbar} \sum_{R} \Delta_p \text{Vol}_R.
\] (6.33)

As was shown in section 5.2, it then follows that the \(1/N\) corrections are resummed to an Airy function:
\[
Z(N) = C^{-1/3} e^A \text{Ai} \left[ C^{-1/3} (N - B) \right] + Z_{np}(N)
\] (6.34)

where
\[
B = n_0 + \frac{C \pi^2}{3}.
\] (6.35)

The above general argument gives an explicit algorithm to compute the constant (6.33). In section 6.3 we consider the example of ABJM theory with matter as an illustration of this argument.
6.3. ABJM theory with fundamental matter

The ABJM theory with matter we will consider is described by a two-node quiver with equal number of fundamentals in each node, see figure 8. The density matrix of this theory is given by (3.57)

\[ \rho_W = \exp\{-H_W\} = e^{-U(q)/2} \star e^{-\Psi(p+q)} \star e^{-T(p)} \star e^{-\Psi(p+q)} \star e^{-U(q)/2} \]  

(6.36)

where \( U(q), T(p) \) are given respectively in (3.30) and (3.31), and

\[ \Psi(p + q) = N_f \log 2 \cosh \frac{p + q}{2k}. \]  

(6.37)

The Wigner transform of the Hamiltonian has the following \( \hbar \) expansion, which can be obtained with the use of the Baker–Campbell–Hausdorff formula:

\[
H_W(p, q) = H_{cl}(p, q) + \frac{\hbar^2}{24}U''(q)^2(2\Psi''(p+q) + T''(p)) - \frac{\hbar^2}{12}(-2\Psi'(p+q))^2(T''(p) - 2U''(q)) + T'(p)^2(2\Psi''(p+q) + U''(q)) + 4T'(p)U''(q)\Psi'(p+q) + \frac{\hbar^2}{6}U'(q)(T''(p)\Psi'(p+q) - T'(p)\Psi''(p+q)) + O(\hbar^4),
\]  

(6.38)

where the first term is the ‘classical’ Hamiltonian:

\[ H_{cl}(p, q) = T(p) + U(q) + 2\Psi(p + q). \]  

(6.39)

The function \( \Psi \) has an asymptotic behavior similar to that of \( T \) and \( U \):

\[ \Psi(Q) = \frac{\alpha}{2}|Q| + O(e^{-c|Q|}), \quad |Q| \gg 1, \]  

(6.40)

where

\[ \alpha = \frac{N_f}{k}. \]  

(6.41)

Since \( H_W \) is real, (6.36) is a particular example of the general case (6.14) considered in the previous subsection. We have three different local coordinates:

\[ Q_1 = q, \quad Q_2 = p, \quad Q_3 = p + q. \]  

(6.42)

For large energy the Fermi surface \( H_W(q, p) = E \) approaches a polygon given by

\[ \frac{|p|}{2} + \frac{|q|}{2} + \alpha|p + q| = E, \]  

(6.43)

see figure 9. Therefore, the leading contribution to the number of states is

\[ n(E) \approx \frac{1}{2\pi\hbar} \text{Vol}\left\{ \frac{|p|}{2} + \frac{|q|}{2} + \alpha|p + q| < E \right\} = CE^2 \]  

(6.44)

4 We use quotation marks because \( \Psi \) still contains \( k = \hbar/(2\pi) \).
where
\[ C = \frac{2(1 + \alpha)}{\pi^2 k(1 + 2\alpha)^2}. \] (6.45)

It follows that
\[ F(N) \approx -\frac{\sqrt{2}}{3} \pi k \frac{1 + 2\alpha}{\sqrt{1 + \alpha}} N^{3/2} \] (6.46)

which reproduces the result of [11,10]. Notice that, as in the case of ABJM theory, the large energy limit of the Fermi surface is closely related to the tropical limit of the spectral curve obtained in [11].

Now let us compute the corrections according to the general scheme described in section 6.2. The regions \( U_R, U'_R \) for \( R = 1–3 \), as well as the lines \( Q_R = 0 \), are shown in figure 10. In the domain \( U_1 \) the Hamiltonian can be written as
\[
H_W(q,p) = p \left( \alpha + \frac{1}{2} \right) + U(q) + q\alpha - \frac{1}{48} \hbar^2 (2\alpha + 1)^2 U''(q) + \sum_{n>1} \hbar^{2n} C_n^1 U^{(2n)}(q) + \mathcal{O}(e^{-\epsilon E}).
\] (6.47)

Therefore we can take
\[ P_1 = p + \frac{\alpha}{1/2 + \alpha} q \] (6.48)

and
\[
\Delta_p P_1(Q_1) = -\frac{2}{1 + 2\alpha} \left\{ U(Q_1) - \frac{|Q_1|}{2} - \frac{1}{48} \hbar^2 (2\alpha + 1)^2 U''(Q_1) + \sum_{n>1} \hbar^{2n} C_n^1 U^{(2n)}(Q_1) \right\},
\] (6.49)

\[
\Delta_p \text{Vol}_1 = -\frac{\pi^2}{3(1 + 2\alpha)} + \frac{\hbar^2 (1 + 2\alpha)}{24}.
\] (6.50)
In the domain $\mathcal{U}_2$ we have
\[
H_W(q,p) = T(p) - p\alpha - q\left(\alpha + \frac{1}{2}\right) + \frac{1}{384}(2\alpha + 1)^2\hbar^2T''(p) + \sum_{n>1} \hbar^{2n}c_n^2T^{(2n)}(p) + \mathcal{O}(e^{-cE}),
\]
therefore
\[
P_2 = -q - \frac{\alpha}{1/2 + \alpha}p
\]
and
\[
\Delta_p P_2(Q_2) = -\frac{2}{1 + 2\alpha}\left\{T(Q_2) - \frac{|Q_2|}{2} + \frac{1}{96}\hbar^2(2\alpha + 1)^2T''(Q_2) + \sum_{n>1} \hbar^{2n}c_n^2T^{(2n)}(Q_2)\right\},
\]
\[
\Delta_p \text{Vol}_2 = -\frac{\pi^2}{3(1 + 2\alpha)} - \frac{\hbar^2(1 + 2\alpha)}{48}.
\]
In the domain $\mathcal{U}_3$
\[
H_W(q,p) = p/2 - q/2 + 2\Psi(p + q) + \frac{1}{48}\hbar^2\Psi''(p + q) + \sum_{n>1} \hbar^{2n}c_n^3\Psi^{(2n)}(p + q) + \mathcal{O}(e^{-cE}).
\]
Therefore
\[
P_3 = \frac{p - q}{2}
\]
and
\[
\Delta_p P_3(Q_3) = -(2\Psi(Q_3) - \alpha|Q_3|) - \frac{1}{48}\hbar^2\Psi''(Q_3) - \sum_{n>1} \hbar^{2n}c_n^3\Psi^{(2n)}(Q_3),
\]
\[
\Delta_p \text{Vol}_3 = -\frac{\hbar^2}{48}\alpha
\]
Finally, we obtain
\[ n_0 = \frac{1}{\pi\hbar} \sum_{R \in \{1,2,3\}} \Delta_p \text{Vol}_R = -\frac{1}{3k(1 + 2\alpha)} + \frac{k}{24} (1 - 3\alpha), \] (6.59)
and we conclude that the partition function is given by the Airy function:
\[ Z(N) = C^{-1/3} e^{A \text{Ai} \left[ C^{-1/3}(N - B) \right]} + Z_{np}(N) \] (6.60)
with
\[ B = n_0 + C\pi^2/3 = \frac{1}{3k(1 + 2\alpha)^2} + \frac{k}{24} (1 - 3\alpha). \] (6.61)

The above procedure can be repeated for other quivers with a Hermitian Hamiltonian in order to determine the precise value of $B$. For example, for the four-node quiver with levels
\[ (k, -2k, 2k, -k), \] (6.62)
one finds
\[ B = \frac{13}{135k} + \frac{k}{8}. \] (6.63)

Clearly, it would be nice to have a close answer for the shift for a more general class of quivers (like, for example, four-node quivers with a Hermitian density matrix). In addition, it would be interesting to compare the shifts (6.61) and (6.63) with a direct calculation from the M-theory/type IIA geometry, as in [27,28].

### 6.4. The massive theory

The techniques developed in this paper can also be applied to a variant of ABJM theory in which the Chern–Simons levels $k_1$, $k_2$ do not add up to zero [52]. We will denote
\[ 2\pi i \theta = \frac{1}{k_1} - \frac{1}{k_2}, \quad \frac{4\pi}{\hbar} = \frac{1}{k_1} - \frac{1}{k_2}, \] (6.64)
so that the original ABJM theory is recovered when $\theta = 0$. Notice that $\theta$ is, in principle, imaginary, but it will be useful to Wick-rotate it to real values (see also [55]). The theory with $k_1 + k_2 \neq 0$ was studied in [52], where it was argued that a non-zero $\theta$ corresponds to a non-zero Romans mass in type IIA supergravity. For this reason, we will call this theory the ‘massive’ theory. The massive theory was further investigated in [53], where it was found that its free energy scales with $N$ as
\[ F(N) \approx (k_1 + k_2)^{1/3} N^{5/3}. \] (6.65)

This scaling was reproduced in [14] from an analysis of the matrix model representing the partition function:
\[ Z(N, \theta) = \frac{1}{N!^2} \int \frac{d^N x}{(2\pi)^N} \frac{d^N y}{(2\pi)^N} \prod_{i < j} [2 \sinh((\mu_i - \mu_j)/2)]^2 [2 \sinh((\nu_i - \nu_j)/2)]^2 \prod_{i,j} [2 \cosh((\mu_i - \nu_j)/2)]^2 \times \exp \left[ \frac{i}{4\pi} \sum_{i=1}^{N} (k_1 \mu_i^2 + k_2 \nu_i^2) \right]. \] (6.66)
The exact planar resolvent of this theory was found, in a somewhat implicit form, in \[54\]. The scaling \(6.65\) can also be derived from this resolvent by using the techniques of \[55\].

In order to apply the Fermi gas picture to this theory, we have to find an appropriate density matrix. An elementary computation leads to

\[
 Z(N, \xi) = \frac{1}{N!} \sum_{\sigma \in S_N} (-1)^{\epsilon(\sigma)} \int d^N x \prod_i \rho(x_i, x_{\sigma(i)}; \theta). \tag{6.67}
\]

where

\[
 \rho(x_1, x_2; \theta) = e^{-1/2U_\theta(x_1)} K(x_1, x_2; \theta) e^{-1/2U_\theta(x_2)}. \tag{6.68}
\]

Here, the one-body potential is given by

\[
 U_\theta(q) = \log \left( 2 \cosh \frac{q}{2} \right) + \frac{\theta}{2} q^2, \tag{6.69}
\]

while the function \(K\) is given by

\[
 K(x_1, x_2; \theta) = \sqrt{1 + \hbar^2 \theta^2 / 4} \int_{-\infty}^{\infty} \frac{dy}{4\pi \hbar \cosh(y/2)} \times \exp \left\{ -\frac{\theta}{2} y^2 - y \left[ \frac{\theta}{2} (x_1 + x_2) + \frac{i}{\hbar} (x_1 - x_2) \right] \right\}. \tag{6.70}
\]

Although \(6.70\) is complicated, its Wigner transform is very simple:

\[
 K_W(q, p; \theta) = \sqrt{1 + \hbar^2 \theta^2 / 4} e^{-T_\theta(q, p)} \tag{6.71}
\]

where

\[
 T_\theta(q, p) = \log \left( 2 \cosh \frac{p}{2} \right) + \frac{\theta}{2} p^2 + \theta pq, \tag{6.72}
\]

and of course

\[
 K_W(q, p; 0) = e^{-T(p)}. \tag{6.73}
\]

The Wigner transform of the density matrix is then

\[
 \rho_W(\theta) = \sqrt{1 + \hbar^2 \theta^2 / 4} e^{-1/2U_\theta(q)} * e^{-T_\theta(q, p)} * e^{-1/2U_\theta(q)}, \tag{6.74}
\]

and defines the Hamiltonian of the theory through

\[
 \rho_W(\theta) = e^{-H_W(\theta)}. \tag{6.75}
\]

For \(\theta = 0\) we recover the density matrix of ABJM theory \(3.39\).

We can now use the technology developed before to analyze the theory. We will content ourselves with an analysis of the thermodynamic limit, which leads to a nice interpretation of the \(N^{5/3}\) behavior found in \[53, 14\]. We will also assume that

\[
 |\theta \hbar| \ll 1, \tag{6.76}
\]

or equivalently that

\[
 \frac{|k_1 + k_2|}{|k_1 - k_2|} \ll 1. \tag{6.77}
\]

In this limit we can safely ignore quantum corrections and just look at the classical
Figure 11. The Fermi surface (6.81) in the $q$–$P$ plane, for $\theta = 1/10$, $k = 1$ and $E = 50$ (left) and $E = 5000$ (right). When the energy is large, the Fermi surface approaches the surface defined by (6.82).

Hamiltonian

$$H_{\text{cl}}(q, P; \theta) = U(q) + T(P - q) + \frac{\theta}{2} P^2 - \frac{1}{2} \log \left( 1 + \frac{\theta^2 \hbar^2}{4} \right),$$

(6.78)

where

$$P = p + q.$$ 

(6.79)

This linear change of variables preserves the volume form in phase space:

$$dq \wedge dP = dq \wedge dp.$$ 

(6.80)

At large $E$ the Fermi surface

$$H_{\text{cl}}(q, P; \theta) = E$$

(6.81)

becomes simply

$$\frac{\theta}{2} P^2 + |q| = E,$$

(6.82)

as we can see in figure 11. Notice that, once $\theta \neq 0$, the equation defining the Fermi surface at large $E$ has a quadratic term in the new momentum coordinate $P$ which dominates at large $E$. In other words, the Fermi gas now has a non-relativistic dispersion relation and this changes the scaling of the free energy. Looking at (4.15) we deduce that

$$s = \frac{3}{2},$$

(6.83)

and therefore the free energy should scale now as $N^{5/3}$, as found in [53, 14]5. We find

$$n(E) \approx \frac{4}{2\pi \hbar} \int_0^{\sqrt{2E/\theta}} dP \left( E - \frac{\theta}{2} P^2 \right) = \frac{4}{3\pi \hbar} \sqrt{\frac{2}{\theta}} E^{3/2}.$$ 

(6.84)

5 The matrix model analyzed in [23] displays the same scaling.

doi:10.1088/1742-5468/2012/03/P03001
The free energy can now be computed from (4.11) and is

$$F(N) \approx -\frac{3}{5} \left(\frac{3\sqrt{2\pi \hbar}}{8}\right)^{2/3} N^{5/3} \theta^{1/3}.$$

(6.85)

If we express this in terms of $k_1 + k_2$ we find

$$F(N) \approx -\frac{3^{5/3}}{5 \times 2^{4/3}} \pi e^{-i\pi/6} (k_1 + k_2)^{1/3} \left(1 + \frac{\theta^2 \hbar^2}{4}\right)^{1/3} N^{5/3}.$$

(6.86)

Since we are assuming (6.76), our result can be written as

$$F(N) \approx -\frac{3^{5/3}}{5 \times 2^{4/3}} \pi e^{-i\pi/6} (k_1 + k_2)^{1/3} N^{5/3},$$

(6.87)

which is precisely what [14] obtained. Notice that, in [14], this result was derived based on an assumption on the behavior of the eigenvalues of the matrix model at large $N$, while here we have obtained it directly. When the parameter $\theta^2 \hbar^2$ is not small, one has to take into account the quantum corrections to the Hamiltonian, and the equation of the Fermi surface is modified. It would be interesting to study in more detail the different regimes that can occur in this theory as we vary the coupling constants.

7. Conclusions and prospects for future work

In this paper we have developed an ideal Fermi gas approach to a large class of CSM theories with $N \geq 3$ supersymmetry. Since the particles in the gas do not interact, all the information of the problem is encoded in the one-particle quantum Hamiltonian. We have seen that the structure of the CSM theory determines the detailed form of this Hamiltonian, which is conveniently encoded in its Wigner transform $H_W$:

$$\text{CSM theory} \rightarrow \text{quantum Hamiltonian} \quad H_W.$$

(7.1)

The semiclassical analysis of this Fermi gas already gives us a lot of information on the original partition function. As we have seen, the leading semiclassical contribution provides an extremely simple derivation of the $N^{3/2}$ behavior in these theories (including the right coefficient), and the next-to-leading correction already encodes the full $1/N$ expansion of the original matrix model. The large energy limit of the Fermi surface is a polytope which encodes the geometry of the dual tri-Sasakian target geometry. In addition, non-perturbative membrane instantons can be computed order by order in $k$ (but at all orders in the membrane winding). We summarize some of the features of the Fermi gas approach, as compared to the 't Hooft expansion, in the following table:

|                         | 't Hooft expansion | Fermi gas   |
|-------------------------|--------------------|-------------|
| Semiclassical limit     | Spectral curve     | Fermi surface |
| Quantum corrections     | Quantum spectral curve | Quantum Hamiltonian |
| Exponentially small corrections | Worldsheet instantons | Membrane instantons |
| Non-perturbative effects | Membrane instantons | Worldsheet instantons |

It would be interesting to understand at a deeper level the Fermi gas picture. Since D-branes behave as fermions (see, for example, [56]) and the gauge theories we have
considered have D-brane realizations, one might be able to derive this picture directly from the D-branes underlying the gauge theory.

Our formalism has many similarities with recent developments in matrix models and topological string theory (see, for some examples, [56]–[58]). The semiclassical limit gives a Fermi surface, which can be regarded as the counterpart to the spectral curve in the conventional 't Hooft expansion. For ABJM theory both curves are the same, but for the more general CSM theories studied in this paper the semiclassical Fermi surface is simpler and easier to find. In fact, the planar resolvent of the CSM matrix models is, in general, not known, and when it is known (as in [54,11]) it turns out to be a complicated transcendental function. It seems, however, that both the Fermi surface and the spectral curve have the same tropical or polygonal limit.

The Fermi surface has quantum corrections and one then obtains a ‘quantum-corrected curve’ nicely encoded in the function $H_W$ in phase space. The quantum corrections appear in a very natural way by replacing standard products by $\star$-products. However, the corrections found in this way are not in the string coupling constant $g_s$, as in conventional topological string theory [56,59] but rather in the inverse string coupling $1/g_s$. Therefore, the quantum Hamiltonian $H_W$ is computing the quantum curve for the strongly coupled string.

More generally, our formalism seems appropriate to study the strong coupling regime of matrix models and topological strings. For example, in the case of ABJM theory, it is known [26,5] that the ABJM matrix model (2.1) corresponds to the submanifold $T_1 = T_2$ of the moduli space of topological strings on local $\mathbb{P}^1 \times \mathbb{P}^1$. Here, $T_{1,2}$ are the Kähler parameters measuring the sizes of the two $\mathbb{P}^1$s in the geometry. However, by looking at, for example, (5.83), it is clear that the grand canonical potential of ABJM theory seems to be directly related to the topological string free energy in the large radius frame. Therefore, our calculation of $J(\mu)$ for the ABJM theory can be interpreted as a concrete strong coupling expansion of this topological string free energy, including non-perturbative effects. The worldsheet instantons of the topological string at large radius would appear then as quantum-mechanical instantons of the Fermi gas. Notice also that the grand canonical partition function, which is the focus of this paper, involves the sum over fluxes first considered in the context of topological strings in [56] and studied from the matrix model point of view in [60]–[62]. Our formalism gives a concrete approach to calculate this object at strong coupling, but one should clarify the relation between the picture proposed here and the non-perturbative approach of [60,61] involving theta functions on the spectral curve. It would be very interesting to develop further all these relationships to topological string theory.

If we stay in the world of CSM theories and their AdS duals, an obvious and important question is to what extent the Fermi gas formalism can be applied to other theories. For example, one should consider, already in the $\mathcal{N}=3$ case, the issue of quantum corrections and possible Airy behavior in theories where the free energy is not real, as well as in theories where the nodes have different ranks [63]. The extension to $\mathcal{N}=2$ theories is more challenging. In that case the interaction among eigenvalues involves a more complicated function [3,4] and they lead generically to interacting Fermi gases, rather than to ideal gases.

Although the equivalence between the matrix models and the Fermi gas partition function is an exact statement at finite $N$ and $k$, in this paper we have worked in the

doi:10.1088/1742-5468/2012/03/P03001
ABJM theory as a Fermi gas

thermodynamic limit (large $N$) and in the semiclassical limit (expansion in powers of $k$ around $k = 0$). Fortunately, as we have seen, the expansion in $1/N$ satisfies some sort of ‘non-renormalization’ property and we can determine it at finite $k$ by a next-to-leading computation in the WKB expansion. An obvious challenge is to solve the Fermi gas problem at finite $k$, say $k = 1$, to make full contact with the M-theory expansion. This would amount to a resummation of the non-perturbative effects computed in this paper order by order in $k$. One possible route to achieve this is to find the exact eigenvalue spectrum of the quantum Hamiltonian, or equivalently, of the density matrix $\hat{\rho}$. In the case of ABJM theory, this means solving the integral equation (3.19), which can be written as

$$\int dx' \rho(x, x')\phi_n(x') = \lambda_n \phi_n(x),$$  \hspace{1cm} (7.2)

where the kernel can be written in the form

$$\rho(x, x') = \frac{e^{-1/2U(x) - 1/2U'(x)}}{4\pi k \cosh((x - x')/2k)}.$$  \hspace{1cm} (7.3)

This type of kernel appears in other contexts, like the $O(2)$ matrix model [22] (albeit with a different $U(x)$), and it is connected to both the Hirota hierarchy [22, 64] and to the thermodynamic Bethe ansatz [65, 66]. At least for $k = 1, 2$ (where supersymmetry is enhanced), we anticipate a nice solution to the eigenvalue problem in terms of an integrable system. In particular, the relation to differentiable hierarchies of the Hirota type suggests that the conjecture 1.1 might be proved by performing a suitable double-scaling limit in the hierarchy.

It would also be very interesting to develop further the relationship between worldsheet instantons and quantum-mechanical instantons of the Fermi gas sketched in section 5.4. It is clear that the solution of the ABJM theory found in [5], in the ‘t Hooft expansion, is extremely powerful in order to capture these corrections, but it would be important for the development of the Fermi gas approach to have a better understanding of this issue.

Finally, there might be a connection between the Fermi gas of this paper and two other pictures for string/M-theory based on fermions: the droplet picture proposed in [67, 68] to analyze 1/2 BPS operators in $\mathcal{N} = 4$ SYM theory and the Fermi liquid picture of non-critical M-theory proposed in [69].

Appendix A. Quantum corrections in ABJM theory at order $O(h^4)$

In this appendix, we give some details on the computation of the order $O(h^4)$ corrections to the grand canonical potential of ABJM theory, which confirm the general arguments of section 5.

The Baker–Campbell–Hausdorff formula applied to (3.39) gives

$$H_W(q,p) = T + U + \frac{1}{1728}[[[T, [T, U]_*], U]_*, U]_* + \frac{1}{360} [[[U, T]_*, [T, U]_*], U]_* + \frac{1}{360} [[[U, T]_*, T]_*, T]_* + \frac{7}{5760} [[[U, T]_*, [U, U]_*], U]_* - \frac{7}{290} [[[U, T]_*, T]_*, T]_* + \cdots. \quad (A.1)$$

This leads to the next correction to the Wigner transform of the Hamiltonian:

$$H_W^{(2)} = \frac{1}{124} T^4(p) T''''(p)(U^4(q) - \frac{1}{256} U''(q) U''''(q) T^4(q)$$

$$- \frac{1}{240} (U''(q))^2 U'''(q)(T''(p))^2 + \frac{1}{60} (T''(p))^2 T''''(p)(U''(q))^2$$

$$- \frac{7}{5760} (U''(q))^4 T^4(p) - \frac{1}{120} T^4(p))^2 U''(q) U''''(q)$$

$$+ \frac{7}{5760} (U''(q))^4 T^4(p) - \frac{1}{120} (T^4(p))^3 U''(q)). \quad (A.2)$$

The computation of $J_2(\mu)$ also involves the $G_r$ defined in (5.3) up to order $O(h^4)$. Due to (5.5) only the terms with $r \leq 6$ are needed. A long but straightforward calculation leads finally to

$$J_2(\mu) = \frac{\pi^2}{4320} + \frac{\pi^2}{720}(104 + 5\pi^2 - 134\mu + 30\mu^2)e^{-2\mu} + O(\mu^2 e^{-4\mu}). \quad (A.3)$$

Notice that no polynomial in $\mu$ is generated, as expected from the analysis in section 5.
