MULTIDIMENSIONAL BORG-LEVINSON TYPE ANALYSIS OF THE ROBIN LAPLACIAN WITH UNBOUNDED POTENTIALS

MOURAD CHOULLI, ABDELMALEK METIDJI, AND ERIC SOCCORSI

Abstract. This article deals with the uniqueness and stability issues in the inverse problem of determining the unbounded potential of the Schrödinger operator in a bounded domain of $\mathbb{R}^n$, $n \geq 3$, endowed with Robin boundary condition, from knowledge of its boundary spectral data. These data are defined by the pairs formed by the eigenvalues and the Dirichlet measurement of the eigenfunctions on the boundary of the domain.

1. Introduction

In the present article $\Omega$ is a $C^{1,1}$ bounded domain of $\mathbb{R}^n$, $n \geq 3$, with boundary $\Gamma$, and we equip the two spaces $H := L^2(\Omega)$ and $V := H^1(\Omega)$ with their usual scalar product.\[\frac{p}{2} := \frac{2n}{n+2}\] and let $p^* := \frac{2n}{n-2}$ be its conjugate number, in such a way that $V$ is continuously embedded in $L^{p^*}(\Omega)$.

1.1. The Robin Laplacian. For $\alpha \in L^\infty(\Gamma, \mathbb{R})$ and $q \in L^{n/2}(\Omega, \mathbb{R})$, we introduce the following continuous sesquilinear form $a : V \times V \rightarrow \mathbb{C}$

$$a(u, v) = \int_{\Omega} \nabla u \cdot \nabla v dx + \int_{\Omega} quv dx + \int_{\Gamma} \alpha u v ds, \quad u, v \in V.$$ 

Throughout the entire text, we assume that $\alpha \geq -c$ for some constant $c \in (0, n-2)$ almost everywhere on $\Gamma$, where $n$ denotes the norm of the (bounded) trace operator $u \in V \mapsto u|_{\Gamma} \in L^2(\Gamma)$. Set $Q(\rho, \kappa) := \{ q \in L^\rho(\Omega, \mathbb{R}); \|q\|_{L^\rho(\Omega)} \leq \kappa \}, \quad \rho \geq n/2, \kappa > 0.$

Then, arguing as in the derivation of [16, Lemma A2], we obtain that

$$\|qu\|_{L^1(\Omega)} \leq \epsilon \|u\|_V^2 + C_\epsilon \|u\|_{H^1}^2, \quad q \in Q(n/2, \kappa), \quad u \in V, \quad \epsilon > 0,$$

for some constant $C_\epsilon > 0$ depending only of $n$, $\Omega$, $\kappa$ and $\epsilon$. Further, applying (1.1) with $\epsilon = \kappa := (1 - cn^2)/2$ yields

$$a(u, u) + \lambda^* \|u\|_{H^1}^2 \geq \kappa \|u\|_V^2, \quad u \in V,$$

where $\lambda^* > 0$ is a constant which depends only on $n$, $\Omega$, $c$ and $\kappa$. Let us consider the bounded operator $A : V \rightarrow V^*$ defined by

$$\langle Au, v \rangle = a(u, v), \quad u, v \in V,$$
where $\langle \cdot, \cdot \rangle$ denotes the duality pairing between an arbitrary Banach space and its dual. Notice that $A$ is self-adjoint and coercive according to (1.2).

1.2. **Boundary spectral data.** With reference to [13, Theorem 2.37], the spectrum of $A$ consists of its eigenvalues $\lambda_k, k \in \mathbb{N} := \{1, 2, \ldots\}$, arranged in non-decreasing order and repeated with the (finite) multiplicity,

$$-\infty < \lambda_1 \leq \lambda_2 \leq \ldots \leq \lambda_k \leq \ldots,$$

and such that

$$\lim_{k \to \infty} \lambda_k = \infty.$$

Moreover, there exists an orthonormal basis $\{\phi_k, k \in \mathbb{N}\}$ of $H$, made of eigenfunctions $\phi_k \in V$ of $A$, satisfying

$$a(\phi_k, v) = \lambda_k (\phi_k, v), \quad v \in V, \quad k \in \mathbb{N},$$

where $(\cdot, \cdot)$ is the usual scalar product in $H$. For the sake of shortness, we write

$$\psi_k := \phi_k|_{\Gamma}, \quad k \in \mathbb{N}.$$

Recall that for $u \in V$, we have $\Delta u \in H^{-1}(\Omega)$, the space dual to $H^1_0(\Omega)$, but that it is not guaranteed that $\Delta u$ lie in $V^*$ (which is strictly embedded in $H^{-1}(\Omega)$). Thus, we introduce

$$W := \{u \in V; \Delta u \in V^*\},$$

Endowed with its natural norm

$$\|u\|_W = \|u\|_V + \|\Delta u\|_V^*, \quad u \in W,$$

is a Banach space. Next, for $\varphi \in H^{1/2}(\Gamma)$, we set

$$\hat{\varphi} := \{v \in V; v|_{\Gamma} = \varphi\},$$

and we equip the space $H^{1/2}(\Gamma)$ with its graph norm

$$\|\varphi\|_{H^{1/2}(\Gamma)} = \min\{\|v\|_V; v \in \hat{\varphi}\}.$$

Now, for $u \in W$ fixed, we put

$$\Phi_u(v) := \langle \Delta u, v \rangle + \langle \nabla u, \nabla v \rangle, \quad v \in V,$$

apply the Cauchy-Schwarz inequality, and get that

$$(1.3) \quad |\Phi_u(v)| \leq \|\Delta u\|_V \|v\|_V + \|u\|_V \|v\|_V \leq \|u\|_W \|v\|_V.$$

Moreover, since $C^\infty_0(\Omega)$ is dense in $H^1_0(\Omega)$, it is easy to see that $H^1_0(\Omega) \subset \ker \Phi_u$ and consequently that $\Phi_u(v)$ depends only on $v|_{\Gamma}$. This enables us to define the normal derivative of $u$, denoted by $\partial_n u$, as the unique vector in $H^{-1/2}(\Gamma)$ satisfying

$$\langle \partial_n u, \varphi \rangle = \Phi_u(v), \quad v \in \hat{\varphi} \text{ is arbitrary}.$$

As a consequence we have

$$\|\partial_n u\|_{H^{-1/2}(\Gamma)} \leq \|u\|_W,$$

by (1.3), and the following generalized Green formula:

$$(1.4) \quad \langle \Delta u, v \rangle + \langle \nabla u, \nabla v \rangle = \langle \partial_n u, v|_{\Gamma} \rangle, \quad u \in W, \quad v \in V.$$

Pick $f \in V^*$ and $\mu \in \mathbb{C}$, and let $u \in V$ satisfy

$$(1.5) \quad a(u, v) + \mu(u, v) = \langle f, v \rangle, \quad v \in V.$$

Using that $C^\infty_0(\Omega) \subset V$, we obtain that

$$\int_{\Omega} \nabla u \cdot \nabla \varphi dx + \int_{\Omega} q u \varphi dx + \mu \int_{\Omega} \varphi dx = \langle f|\varphi \rangle, \quad v \in C^\infty(\Omega),$$

where $\langle \cdot, \cdot \rangle$ denotes the duality pairing between an arbitrary Banach space and its dual. Notice that $A$ is self-adjoint and coercive according to (1.2).
which yields $-\Delta u + qu + \mu u = f$ in $\mathcal{D}'(\Omega)$. Thus, bearing in mind that $qu \in V^*$, we have $u \in W$, and the generalized Green formula (1.4) provides
\[(\partial_{\nu}u + \alpha u|_{\Gamma}, v|_{\Gamma}) = 0, \quad v \in V.\]
Since $v \in V \Rightarrow v|_{\Gamma} \in H^{1/2}(\Gamma)$ is surjective, the above line reads $\partial_{\nu}u + \alpha u|_{\Gamma} = 0$, showing that (1.5) is the variational formulation of the following boundary value problem (BVP):
\[(-\Delta + q + \mu)u = f \text{ in } \Omega, \quad \partial_{\nu}u + \alpha u|_{\Gamma} = 0 \text{ on } \Gamma.\]
Thus, taking $\mu = \lambda_k$ for all $k \in \mathbb{N}$, we find that $\phi_k \in W$ satisfies
\[(1.6) \quad (-\Delta + q - \lambda_k)\phi_k = 0 \text{ in } \Omega, \quad \partial_{\nu}\phi_k + \alpha\phi_k|_{\Gamma} = 0 \text{ on } \Gamma.\]

1.3. Statement of the results. We stick to the notations of the previous sections, that is to say that we write $\lambda_k$ (resp., $\tilde{\phi}_k$, $\tilde{\psi}_k$), $k \in \mathbb{N}$, instead of $\lambda_k$ (resp., $\phi_k$, $\psi_k$) when the potential $\tilde{q}$ is substituted for $q$. Our first result is as follows.

**Theorem 1.1.** Let $q$ and $\tilde{q}$ be in $L^r(\Omega, \mathbb{R})$, where $r = n/2$ when $n \geq 4$ and $r > n/2$ when $n = 3$, and let $\ell \in \mathbb{N}$. Then, the conditions
\[\lambda_k = \tilde{\lambda}_k \text{ for all } k \geq \ell \quad \text{and} \quad \psi_k = \tilde{\psi}_k \text{ on } \Gamma \text{ for all } k \geq 1,
\]
yield that $q = \tilde{q}$ in $\Omega$.

The claim of Theorem 1.1 was first established for smooth bounded potentials, in the peculiar case where $\ell = 1$, by Nachman, Sylvester and Uhlmann in [14]. In the same context (of smooth bounded potentials), their result was extended to $\ell \geq 1$ through a heuristic approach in [19].

In view of stating our stability results, let us denote by $\ell^\infty$ (resp. $\ell^2$) the Banach (resp., Hilbert) space of bounded (resp. squared summable) sequences of complex numbers $(z_k)$, equipped with the norm
\[\|z_k\|_{\ell^\infty} := \sup_{k \geq 1} |z_k| \quad \text{resp.}, \quad \|z_k\|_{\ell^2} := \left(\sum_{k \geq 1} |z_k|^2\right)^{1/2},\]
and let $\ell^2(L^2(\Gamma)) := \{w_k \in L^2(\Gamma)^n \text{ such that } \|w_k\|_{L^2(\Gamma)} \in \ell^2\}$ be endowed with its natural norm
\[\|(w_k)\|_{\ell^2(L^2(\Gamma))} := \|(w_k)\|_{\ell^2}.
\]

**Theorem 1.2.** Fix $\mathcal{R} \in (0, \infty)$ and let $(q, \tilde{q}) \in Q(r, \mathcal{R})^2$, where $r = n/2$ when $n \geq 4$ and $r > n/2$ when $n = 3$, satisfy $q - \tilde{q} \in L^2(\Omega)$. Assume that $(\lambda_k - \tilde{\lambda}_k) \in \ell^\infty$ fulfills $\|(\lambda_k - \tilde{\lambda}_k)\|_{\ell^\infty} \leq \mathcal{R}$ and that $(\tilde{\psi}_k - \psi_k) \in \ell^2(L^2(\Gamma))$. Then, we have
\[\|q - \tilde{q}\|_{H^{-1}(\Omega)} \leq C \left(\|(\lambda_k - \tilde{\lambda}_k)\|_{\ell^\infty} + \|(\tilde{\psi}_k - \psi_k)\|_{\ell^2(L^2(\Gamma))}\right)^{2(1-2\beta)/(3(2+n))},\]
where $\beta := \max(0, n(2 - r)/(2r))$ and $C$ is a positive constant depending only on $n$, $\Omega$, $\mathcal{R}$ and $\epsilon$.

**Remark 1.1.** (i) It is worth noticing that $\beta = 0$ when $n \geq 4$, whereas $\beta \in (0, 1/2)$ when $n = 3$.
(ii) We have $q - \tilde{q} \in L^2(\Omega)$ for all $(q, \tilde{q}) \in Q(n/2, \mathcal{R})^2$, provided that $n \geq 4$. Nevertheless, this is no longer true when $n = 3$, even if $(q, \tilde{q})$ is taken in $Q(r, \mathcal{R})^2$ with $r \in (n/2, 2)$. Hence the additional requirement of Theorem 1.2 that $q - \tilde{q} \in L^2(\Omega)$
in the three-dimensional case.

(iii) When \( q - \tilde{q} \in L^\infty(\Omega) \), we have \( (\lambda_k - \tilde{\lambda}_k) \in \ell^\infty \) and \( \| (\lambda_k - \tilde{\lambda}_k) \|_{\ell^\infty} \leq \| q - \tilde{q} \|_{L^\infty(\Omega)} \), by the min-max principle. Thus, Theorem 1.2 remains valid by replacing the condition \( \| (\lambda_k - \tilde{\lambda}_k) \|_{\ell^\infty} \leq \aleph \) by the stronger assumption \( \| q - \tilde{q} \|_{L^\infty(\Omega)} \leq \aleph \).

To the best of our knowledge, there is no comparable stability result available in the mathematical literature for Robin boundary conditions, even when the potentials are assumed to be bounded. Nevertheless, it should be pointed out that the variable coefficients case was recently addressed by [2] in the framework of Dirichlet boundary conditions.

1.4. A short bibliography. The first published uniqueness result for the multidimensional Borg-Levinson problem can be found in [14]. The breakthrough idea of the authors of this article was to relate the inverse spectral problem under analysis to the one of determining the bounded potential by the corresponding elliptic Dirichlet-to-Neumann map. This can be understood from the fact that, the Schwartz kernel of the elliptic Dirichlet-to-Neumann operator can be, at least heuristically, fully expressed in terms of the eigenvalues and the normal derivatives of the eigenfunctions. Later on, [10] proved that the result of [14], which assumes complete knowledge of the boundary spectral data, remains valid when finitely many of them remain unknown.

The stability issue for multidimensional Borg-Levinson type problems was first examined in [1]. The authors proceed by relating the spectral data to the corresponding hyperbolic Dirichlet-to-Neumann operator, which stably determines the bounded electric potential. We refer the reader to [3, 4, 5] for alternative inverse stability results based on this approach.

In all the above mentioned results, the number of unknown spectral data is at most finite (that is to say that the data are either complete or incomplete). Nevertheless, it was proved in [8] that asymptotic knowledge of the boundary spectral data is enough to Hölder stably retrieve the bounded potential. This result was improved in [11, 20] by removing all quantitative information on the eigenfunctions of the stability inequality, at the expense of an additional summability condition on their boundary measurements.

In all the articles cited up to this point in this section, the unknown potential is supposed to be bounded. The unique determination of unbounded potentials by either complete or incomplete boundary spectral data is discussed in [15, 16], whereas the stability issue for the same problem, but in the variable coefficients case, is examined in [2]. As for the treatment of the inverse problem of determining the unbounded potential from asymptotic knowledge of the spectral data, we refer the reader to [6] for the uniqueness issue, and to [12] for the stability issue.

All the results cited above were obtained for multidimensional Laplace operators endowed with Dirichlet boundary conditions, except for [14] which proved that full knowledge of the boundary spectral data of the Robin Laplacian uniquely determines the unknown electric potential. But, apart from the claim, based on a heuristic approach, of [19], that incomplete knowledge of the spectral data of the multidimensional Robin Laplacian uniquely determines the unknown bounded potential, it seems that, even for a bounded unknown potential \( q \), there is no reconstruction result of \( q \) by incomplete spectral data, available in the mathematical
literature for such operators. The main achievements of this article are unique identification and Hölder stable determination Borg-Levinson type results for a singular potential of the multidimensional Robin Laplacian, by incomplete spectral data.

1.5. Outline. The remaining part of this paper is structured as follows. In Section 2 we gather several technical results which are needed by the proof of the two main results of this article. The proof of Theorems 1.1 and 1.2 is given in Section 3.

2. Preliminaries

In this section we collect several preliminary results that are needed by the proof of the main results of this article. We start by noticing, upon applying (1.2) with \( u = \phi_k, \ k \geq 1 \), that

\[
\lambda_k > -\lambda^*, \quad k \geq 1.
\]

2.1. Resolvent estimates. By [13, Corollary 2.39], the operator \( A - \lambda : V \to V^* \) has a bounded inverse whenever \( \lambda \in \rho(A) \equiv \mathbb{C} \setminus \sigma(A) \), the resolvent set of \( A \). Furthermore, for all \( f \in V^* \) we have

\[
(A - \lambda)^{-1} f = \sum_{k \geq 1} \frac{\langle f, \phi_k \rangle}{\lambda_k - \lambda} \phi_k,
\]

where the series converges in \( V \). For further use, we now establish that the resolvent \( (A - \lambda)^{-1} \) may regarded as a bounded operator from \( H \) into the space \( K := \{ u \in H; \ Au \in H \} \) endowed with the norm

\[
\| u \|_K := \| u \|_H + \| Au \|_H, \quad u \in K.
\]

Lemma 2.1. For all \( \lambda \in \rho(A) \), the operator \( (A - \lambda)^{-1} \) is bounded from \( H \) into \( K \).

Proof. Put \( u := (A - \lambda)^{-1} f \) where \( f \in H \) is fixed. Then, we have \( (u, \phi_k) = (f, \phi_k)/(\lambda_k - \lambda) \) for all \( k \geq 1 \), from (2.2), whence

\[
Au = \sum_{k \geq 1} \frac{\lambda_k}{\lambda_k - \lambda} (f, \phi_k) \phi_k,
\]

according to [13, Theorem 2.37], the series being convergent in \( V^* \). Moreover, since

\[
\sum_{k \geq 1} \frac{\lambda_k^2}{|\lambda_k - \lambda|^2} \| (f, \phi_k) \|^2 \leq \| (\lambda_k/(\lambda_k - \lambda)) \|_{L^\infty} \| f \|_H^2 < \infty,
\]

by the Parseval theorem, the right hand side on (2.3) lies in \( H \). Therefore, we have \( Au \in H \) and \( \| Au \|_H \leq \| (\lambda_k/(\lambda_k - \lambda)) \|_{L^\infty} \| f \|_H \), and consequently \( u \in K \) and \( \| u \|_K \leq \| (1 + \lambda_k)/(\lambda_k - \lambda) \|_{L^\infty} \| f \|_H \). \( \square \)

Proposition 2.1. Let \( q \in \mathbb{Q}(n/2, \mathbb{N}) \) and let \( \lambda \in \rho(A) \). Then, for all \( f \in V^* \), the following estimate

\[
\| (A - \lambda)^{-1} f \|_V \leq C \| (\lambda_k + \lambda^*)/(\lambda_k - \lambda) \|_{L^\infty} \| f \|_{V^*},
\]

holds with \( C = \kappa^{-1/2} \| (A + \lambda^*)^{-1} \|_{\mathcal{B}(V^*, V)} \), where \( \mathcal{B}(V^*, V) \) denotes the space of linear bounded operators from \( V^* \) to \( V \). Moreover, in the special case where \( f \in H \), we have

\[
\| (A - \lambda)^{-1} f \|_H \leq \| 1/(\lambda_k - \lambda) \|_{L^\infty} \| f \|_H.
\]
Proof. Since (2.5) follows directly from (2.2) and the Parseval formula, it is enough to prove (2.4). To this purpose we set \( u := (A - \lambda)^{-1}f \) and notice from the obvious identity \( \Delta u = (q - \lambda)u - f \in V^* \) that \( u \in W \). Therefore, by applying (1.4) with \( v = u \), we infer from the coercivity estimate (1.2) that
\[
\kappa \|u\|_V^2 \leq \langle (A + \lambda^*)u, u \rangle_{V^*, V}.
\]
Let us assume for a while that \( f \in H \). Then, with reference to (2.3), we have
\[
(A + \lambda^*)u = \sum_{k \geq 1} \frac{\lambda_k + \lambda^*}{\lambda_k - \lambda} (f, \phi_k) \phi_k,
\]
where the series converges in \( H \). It follows from this, (2.2) and (2.6) that
\[
\kappa \|u\|_V^2 \leq \sum_{k \geq 1} \frac{\lambda_k + \lambda^*}{|\lambda_k - \lambda|^2} |(f, \phi_k)|^2 \leq \|((\lambda_k + \lambda^*)/(\lambda_k - \lambda))\|_{\infty}^2 \sum_{k \geq 1} \frac{|(f, \phi_k)|^2}{\lambda_k + \lambda^*}.
\]
Further, taking into account that
\[
\sum_{k \geq 1} \frac{|(f, \phi_k)|^2}{\lambda_k + \lambda^*} = \|(A + \lambda^*)^{-1}f\|_H^2
\]
according to (2.2) and the Parseval formula, and then using that \( \|(A + \lambda^*)^{-1}f\|_H \leq \|((A + \lambda^*)^{-1}\|_{B(V^*, V)}\|f\|_{V^*} \), we infer from (2.7) that
\[
\|u\|_V \leq \kappa^{-1/2}\|(A + \lambda^*)^{-1}\|_{B(V^*, V)} \|((\lambda_k + \lambda^*)/(\lambda_k - \lambda))\|_{\infty} \|f\|_{V^*}.
\]
Finally, keeping in mind that \( u = (A - \lambda)^{-1}f \) and that \( (A - \lambda)^{-1} \in B(V^*, V) \), (2.4) follows readily from (2.8) by density of \( H \) in \( V^* \).

As a byproduct of Proposition 2.1, we have the following:

**Corollary 2.1.** Let \( q \in Q(n/2, \mathbb{N}) \). Then, for all \( \tau \in [1, +\infty) \) we have
\[
\|(A - (\tau + i)^2)^{-1}f\|_H \leq (2\tau)^{-1}\|f\|_H, \quad f \in H.
\]
Moreover, for all \( \tau \geq \tau^* := 1 + (\max(0, 2 - \lambda^*))^{1/2} \), we have
\[
\|(A - (\tau + i)^2)^{-1}f\|_V \leq C(\tau + \lambda^*)\|f\|_{V^*}, \quad f \in V^*,
\]
where \( C \) is the same constant as in (2.4).

**Proof.** As (2.9) is a straightforward consequence of (2.5), we shall only prove (2.10). To do that, we refer to (2.4) and notice that
\[
\frac{\lambda_k + \lambda^*}{|\lambda_k - (\tau + i)|^2} = \frac{\lambda_k + \lambda^*}{((\lambda_k - (\tau^2 - 1))^2 + 4\tau^2)^{1/2}} \leq 2\Theta(\lambda_k), \quad k \geq 1,
\]
where we have set \( \Theta(t) := (t + \lambda^*)/|(t - (\tau^2 - 1)) + 2\tau| \) for all \( t \in [-\lambda^*, \infty) \). Further, taking into account that \( \Theta \) is a decreasing function on \([\tau^2 - 1, \infty)\), provided that \( \tau \geq \tau^* \), we easily get that
\[
\sup_{t \in [-\lambda^*, +\infty]} \Theta(t) \leq \frac{\tau^2 - 1 + \lambda^*}{2\tau} \leq \frac{\tau + \lambda^*}{2},
\]
which along with (2.4) and (2.11), yields (2.10). \( \square \)
Proposition 2.2. Let \( q \in \mathbb{Q}(n/2, \mathbb{R}) \). Then, there exists a constant \( C > 0 \), depending only on \( n, \Omega, c \) and \( \mathbb{R} \), such that for all \( \sigma \in [0, 1] \) and all \( f \in L^p(\Omega) \), we have
\[
\|(A - (\tau + i)^2)^{-1}f\|_{L^p(\Omega)} \leq C\|f\|_{L^p(\Omega)}, \quad \tau \in [\tau^*, \infty),
\]
where \( p_{\sigma} := 2n/(n + 2\sigma) \) and \( p_{\sigma}^* := 2n/(n - 2\sigma) \) is the conjugate integer to \( p_{\sigma} \).

Proof. In light of (2.10), we have for all \( f \in L^p(\Omega) \),
\[
\|(A - (\tau + i)^2)^{-1}f\|_{L^p(\Omega)} \leq C\|f\|_{L^p(\Omega)}, \quad \tau \in [\tau^*, \infty),
\]
by the Sobolev embedding theorem, where \( C \) is a positive constant depending only on \( n, \Omega, c \) and \( \mathbb{R} \). Thus, (2.12) follows from this and (2.9) by interpolating between \( H = L^{p_c}(\Omega) \) and \( L^p(\Omega) = L^{p_1}(\Omega) \) with the aid of the Riesz-Thorin theorem (see, e.g. [17, Theorem IX.17]) \( \square \)

2.2. Asymptotic spectral analysis. Set \( \mathfrak{H} := H^2(\Omega) \) if \( n \neq 4 \) and put \( \mathfrak{H} := H^{2+\epsilon}(\Omega) \) for some arbitrary \( \epsilon > 0 \), if \( n = 4 \). We notice that \( \mathfrak{H} \subset L^\infty(\Omega) \) and that the embedding is continuous, provided that \( n = 3 \) or \( n = 4 \), while \( \mathfrak{H} \) is continuously embedded in \( L^{2n/(n-4)}(\Omega) \) when \( n > 4 \). The main purpose for bringing \( \mathfrak{H} \) into the analysis here is the following useful property: \( fu \in H \) whenever \( f \in L^{\max(2,n/2)}(\Omega) \) and \( u \in \mathfrak{H} \).

Next we introduce the subspace
\[
h := \{ g = \partial_g G + \alpha G|_\Gamma; G \in \mathfrak{H} \}
\]
of \( L^2(\Gamma) \), equipped with its natural quotient norm
\[
\|g\|_h := \min\{|\|G\|_\mathfrak{H}; G \in \mathfrak{H}\}, \quad g \in h,
\]
where
\[
\mathfrak{H} := \{ G \in \mathfrak{H}; \partial_g G + \alpha G|_\Gamma = g \}, \quad g \in h,
\]
and we consider the non homogenous BVP:
\[
(\Delta + q - \lambda)u = 0 \quad \text{in} \ \Omega, \quad \partial_g u + \alpha u|_\Gamma = g \quad \text{on} \ \Gamma.
\]

We first examine the well-posedness of (2.13).

Lemma 2.2. Let \( \lambda \in \rho(A) \) and let \( g \in h \). Then, the function
\[
u(\lambda)(g) := (A - \lambda)^{-1}(\Delta - q + \lambda)G + G
\]
is independent of \( G \in \mathfrak{H} \). Moreover, \( u(\lambda)(g) \in W \) is the unique solution to (2.13) and is expressed as
\[
(2.15) \quad u(\lambda)(g) = \sum_{k \geq 1} \frac{\langle g, \psi_k \rangle}{\lambda_k - \lambda} \phi_k
\]
in \( H \), where \( \langle \cdot, \cdot \rangle \) denotes the usual scalar product in \( L^2(\Gamma) \).

Proof. Since \( G \in \mathfrak{H} \), it is clear that \( (\Delta - q + \lambda)G \in H \). Thus, the right hand side of (2.14) lies in \( W \) and it is obviously a solution to the BVP (2.13). Moreover, \( \lambda \) being taken in the resolvent set of \( A \), this solution is unique.

Further, for all \( G_1 \) and \( G_2 \) in \( \mathfrak{H} \), it is easy to check that \( \partial_g (G_1 - G_2) + \alpha (G_1 - G_2) = 0 \) on \( \Gamma \) and that \( (A - \lambda)^{-1}(\Delta - q + \lambda)(G_1 - G_2) = -(G_1 - G_2) \) in \( \Omega \). Therefore, the function \( u(\lambda)(g) \) given by (2.14), is independent of \( G \in \mathfrak{H} \).
We turn now to showing (2.15). To do that we apply the generalized Green formula (1.4) with \( u = u_\lambda(g) \) and \( v = \phi_k, \ k \geq 1 \). We obtain
\[
\langle \Delta u_\lambda(g), \phi_k \rangle + (\nabla u_\lambda(g) \nabla \phi_k) = \langle \partial_v u_\lambda(g), \psi_k \rangle,
\]
which may be equivalently rewritten as
\[
(q - \lambda)u_\lambda(g), (q \phi_k) + (\nabla u_\lambda(g), \nabla \phi_k) = \langle g - \alpha u_\lambda(g) \rangle, \psi_k \rangle.
\] (2.16)
Doing the same with \( u = \phi_k \) and \( v = u_\lambda(g) \), and taking the conjugate of both sides of the obtained equality, we find that
\[
(u_\lambda(g), (q - \lambda_k) \phi_k) + (\nabla u_\lambda(g), \nabla \phi_k) = -\langle u_\lambda(g) \rangle, \alpha \psi_k \rangle.
\]
Bearing in mind that \( q \) and \( \alpha \) are real-valued, and that \( \lambda_k \in \mathbb{R} \), this entails that
\[
((q - \lambda_k)u_\lambda(g), \phi_k) + (\nabla u_\lambda(g), \nabla \phi_k) = -\langle \alpha u_\lambda(g) \rangle, \psi_k \rangle.
\] (2.17)
Now, taking the difference of (2.16) with (2.17), we end up getting that
\[
(\lambda_k - \lambda)(u_\lambda(g), \phi_k) = (g, \psi_k) = (g, \psi_k).
\]
This and the basic identity
\[
u_\lambda(g) = \sum_{k \geq 1} (u, \phi_k) \phi_k
\]
yield (2.15).

The series on the right hand side of (2.15) converges only in \( H \) and thus we cannot deduce an expression of the trace \( u_\lambda(g) \) in \( \Omega \) and that \( \partial\nu u_\lambda = \nabla \phi_k \) cannot deduce an expression of the trace \( u_\lambda(g) \) in \( \Omega \) and that \( \partial\nu u_\lambda = \nabla \phi_k \).

Lemma 2.3. Let \( g \in \mathfrak{h} \). Then, for all \( \lambda \) and \( \mu \) in \( \rho(A) \), we have
\[
u_\lambda(g) \Gamma - \nu_\mu(g) \Gamma = (\lambda - \mu) \sum_{k \geq 1} \frac{(g, \psi_k)}{(\lambda_k - \lambda)(\lambda_k - \mu)} \psi_k,
\] (2.18)
and the series converges in \( H^{1/2}(\Gamma) \).

Proof. Notice that
\[
(-\Delta + g - \lambda)(u_\lambda - \nu_\mu) = (\lambda - \mu)u_\mu
\]
in \( \Omega \) and that \( \partial\nu (u_\lambda - \nu_\mu) + \alpha(u_\lambda - \nu_\mu) | \Gamma \) = 0 on \( \Gamma \), where, for shortness sake, we write \( u_\lambda = u_\lambda(g) \) and \( u_\mu = u_\mu(g) \). Thus, we have
\[
u_\lambda - \nu_\mu = (\lambda - \mu)(A - \lambda)^{-1} \nu_\mu = (\lambda - \mu) \sum_{k \geq 1} \frac{(u_\mu, \phi_k)}{\lambda_k - \lambda} \phi_k.
\]

On the other hand, since
\[
(u_\mu, \phi_k) = \frac{(g, \psi_k)}{\lambda_k - \mu}, \ k \geq 1,
\]
from (2.15), we obtain that
\[
u_\lambda - \nu_\mu = (\lambda - \mu) \sum_{k \geq 1} \frac{(g, \psi_k)}{(\lambda_k - \lambda)(\lambda_k - \mu)} \phi_k.
\] (2.19)

Moreover, we have
\[
\sum_{k \geq 1} \frac{(g, \psi_k)}{(\lambda_k - \lambda)(\lambda_k - \mu)} (A - \lambda) \phi_k = \sum_{k \geq 1} \frac{(g, \psi_k)}{\lambda_k - \mu} \phi_k,
\]
the series being convergent in $H$. It follows from this and (2.19) that

$$u_\lambda - u_\mu = (\lambda - \mu)(A - \lambda)^{-1} \sum_{k \geq 1} \frac{(g, \psi_k)}{\lambda_k - \mu} \phi_k,$$

where the series on the right hand side of (2.20) converges in $V$. As a consequence we have

$$u_\lambda|_{\Gamma} - u_\mu|_{\Gamma} = (\lambda - \mu) \sum_{k \geq 1} \frac{(g, \psi_k)}{(\lambda_k - \lambda)(\lambda_k - \mu)} \psi_k,$$

the series being convergent in $H^{1/2}(\Gamma)$. □

Next, we establish the following a priori estimate for the solution to (2.13).

**Lemma 2.4.** Let $q \in Q(n/2, R)$. Then, there exist two constants $\lambda_+ > 0$ and $C > 0$, depending only on $n$, $\Omega$, $\mathcal{R}$ and $\mathcal{E}$, such that for all $\lambda \in (-\infty, -\lambda_+]$ and all $g \in \mathcal{H}$, the solution $u_\lambda(g)$ to (2.13) satisfies the estimate

$$|\lambda|^{1/2} \|u_\lambda(g)\|_H + \|u_\lambda(g)\|_V \leq C \|g\|_{L^2(\Gamma)}.$$

**Proof.** Fix $\lambda \in \rho(A) \cap (-\infty, 0)$. We apply the generalized Green formula (1.4) with $u = v := u_\lambda$, where we write $u_\lambda$ instead of $u_\lambda(g)$. We get that

$$\lambda \|u_\lambda\|^2_H + \|\nabla u_\lambda\|^2_H \leq \|\alpha u_\lambda, u_\lambda\| + (g, u_\lambda).$$

Next, $\epsilon$ being fixed in $(0, +\infty)$, we combine (1.1) with (2.22) and obtain

$$\lambda \|u_\lambda\|^2_H + \|\nabla u_\lambda\|^2_H \leq \epsilon \|u_\lambda\|^2_V + C_\epsilon \|u_\lambda\|^2_H + \kappa n \|u_\lambda\|_{L^2(\Gamma)} V_{\Omega} + \kappa n \|u_\lambda\|_{L^2(\Gamma)} V_{\Omega},$$

where $C_\epsilon$ is a positive constant depending only on $n$, $\Omega$, $\mathcal{R}$ and $\epsilon$. Taking $\epsilon = \kappa = (1 - \kappa n^2)/2$ in (2.23) then yields

$$\|u_\lambda\|^2_V + \kappa \|u_\lambda\|^2_{\Omega} \leq n \|g\|_{L^2(\Gamma)} \|u_\lambda\|_{\Omega}.$$ 

As a consequence we have

$$\|u_\lambda\|^2_H + \|u_\lambda\|^2_{\Omega} \leq 2 \kappa^2 n \|g\|^2_{L^2(\Gamma)},$$

whenever $|\lambda| \geq (1 + C_\kappa)/(1 - \kappa^4/4)$, and (2.21) follows readily from this. □

Armed with Lemma 2.4 we can examine the dependence of (the trace of) the solution to the BVP (2.13) with respect to $q$. More precisely, we shall establish that the influence of the potential on $u_\lambda(g)$ is, in some sense, dimmed as the spectral parameter $\lambda$ goes to $-\infty$.

**Lemma 2.5.** Let $q$ and $\tilde{q}$ be in $Q(n/2, \mathcal{H})$. Then, for all $g \in \mathcal{H}$, we have

$$\lim_{\lambda \to -\infty} \|u_\lambda(g)|_{\Gamma} - \tilde{u}_\lambda(g)|_{\Gamma}\|_{H^{1/2}(\Gamma)} = 0.$$

**Proof.** Let $\lambda \in (-\infty, -\lambda_+]$, where $\lambda_+$ is the same as in Lemma 2.4. We use the same notation as in the proof of Lemma 2.4 and write $u_\lambda$ (resp., $\tilde{u}_\lambda$) instead of $u_\lambda(g)$ (resp., $\tilde{u}_\lambda(g)$). Since

$$(-\Delta + q - \lambda)(u_\lambda - \tilde{u}_\lambda) = (\tilde{q} - q)\tilde{u}_\lambda \quad \text{in } \Omega$$

and

$$\partial_{\nu}(u_\lambda - \tilde{u}_\lambda) + \alpha(u_\lambda - \tilde{u}_\lambda)|_{\Gamma} = 0 \quad \text{on } \Gamma,$$

we have

$$u_\lambda - \tilde{u}_\lambda = (A - \lambda)^{-1}((\tilde{q} - q)\tilde{u}_\lambda),$$

and

$$\partial_{\nu}(u_\lambda - \tilde{u}_\lambda) + \alpha(u_\lambda - \tilde{u}_\lambda)|_{\Gamma} = 0 \quad \text{on } \Gamma,$$

we have

$$u_\lambda - \tilde{u}_\lambda = (A - \lambda)^{-1}((\tilde{q} - q)\tilde{u}_\lambda),$$

and

$$\partial_{\nu}(u_\lambda - \tilde{u}_\lambda) + \alpha(u_\lambda - \tilde{u}_\lambda)|_{\Gamma} = 0 \quad \text{on } \Gamma,$$

we have

$$u_\lambda - \tilde{u}_\lambda = (A - \lambda)^{-1}((\tilde{q} - q)\tilde{u}_\lambda),$$

and

$$\partial_{\nu}(u_\lambda - \tilde{u}_\lambda) + \alpha(u_\lambda - \tilde{u}_\lambda)|_{\Gamma} = 0 \quad \text{on } \Gamma.$$
whence
\begin{equation}
\|u_\lambda - \bar{u}_\lambda\|_V \leq C \|(\lambda_k + \lambda^*)/(\lambda_k - \lambda)\|_\ell^\infty \|q\|_\ell^\infty \|\bar{u}_\lambda\|_{V^*},
\end{equation}
by (2.4), where \( C \) is a positive constant which is independent of \( \lambda \).

We are left with the task of estimating \( \|q\|_{V^*} \). For this purpose, we notice from \( q \in L^{n/2}(\Omega) \) and from \( \bar{u}_\lambda \in L^{p^*}(\Omega) \) that \( (\bar{q} - q)\bar{u}_\lambda \in L^p(\Omega) \). Thus, bearing in mind that the embedding \( V \subset L^{p^*}(\Omega) \) is continuous, we infer from Hölder’s inequality that
\[
\|(\bar{q} - q)\bar{u}_\lambda\|_{V^*} \leq \|\bar{q} - q\|_{L^{n/2}(\Omega)} \|\bar{u}_\lambda\|_{L^{p^*}(\Omega)} + 2N\|\bar{u}_\lambda\|_V.
\]
In light of (2.21), this entails that
\[
\|(\bar{q} - q)\bar{u}_\lambda\|_{V^*} \leq C\|g\|_{L^2(\Gamma)},
\]
for some constant \( C \) depending only on \( n, \Omega, \mathcal{H} \) and \( c \). From this, (2.25) and the continuity of the trace operator \( w \in V \mapsto w|_\Gamma \in H^{1/2}(\Gamma) \), we obtain that
\[
\|(u_\lambda)|_\Gamma - (\bar{u}_\lambda)|_\Gamma\|_{H^{1/2}(\Gamma)} \leq C\|((\lambda_k + \lambda^*)/(\lambda_k - \lambda))\|_{\ell^\infty} \|g\|_{L^2(\Gamma)},
\]
where \( C \) is independent of \( \lambda \). Now (2.24) follows immediately from this upon sending \( \lambda \) to \(-\infty\) on both sides of the above inequality. \( \square \)

3. Proof of Theorems 1.1 & 1.2

3.1. Proof of Theorem 1.1. We use the same notations as in the previous sections. Namely, we denote by \( \bar{A} \) the operator generated in \( H \) by \( a \) where \( \bar{q} \) is substituted for \( q \), and we write \( u_\lambda \) (resp., \( \bar{u}_\lambda \)) instead of \( u_\lambda(g) \) (resp., \( \bar{u}_\lambda(g) \)). Let \( \lambda \in \mathbb{C} \setminus \mathbb{R} \) and pick \( \mu \) in \( \rho(\bar{A}) \cap \rho(\bar{A}^\dagger) \). Depending on whether \( \ell = 1 \) or \( \ell \geq 2 \), we have either
\[
(u_\lambda)|_\Gamma - (u_\mu)|_\Gamma = (\bar{u}_\lambda)|_\Gamma - (\bar{u}_\mu)|_\Gamma
\]
or
\[
(u_\lambda)|_\Gamma - (u_\mu)|_\Gamma - (\lambda - \mu) \sum_{k=1}^{\ell-1} \frac{(g, \psi_k)}{(\lambda_k - \lambda)(\lambda_k - \mu)} \psi_k
= (\bar{u}_\lambda)|_\Gamma - (\bar{u}_\mu)|_\Gamma - (\lambda - \mu) \sum_{k=1}^{\ell-1} \frac{(g, \psi_k)}{(\lambda_k - \lambda)(\lambda_k - \mu)} \psi_k,
\]
by virtue of (2.18). Sending \( \Re \mu \) to \(-\infty\) in these two identities, we get with the help of (2.24) that
\begin{equation}
(u_\lambda)|_\Gamma - (\bar{u}_\lambda)|_\Gamma = R_\lambda^\ell,
\end{equation}
where
\[
R_\lambda^\ell = R_\lambda^\ell(g) := \begin{cases} 0 & \text{if } \ell = 1 \\ \sum_{k=1}^{\ell-1} \frac{(\lambda_k - \lambda)(g, \psi_k)}{(\lambda_k - \lambda)(\lambda_k - \mu)} \psi_k & \text{if } \ell \geq 2. \end{cases}
\]
Notice for further use that there exists \( \lambda_* > 0 \) such that the estimate
\begin{equation}
|\langle R_\lambda^\ell, h \rangle| \leq C_{\ell} \frac{\|g\|_{L^2(\Gamma)}\|h\|_{L^2(\Gamma)}}{\lambda^2}, \quad |\lambda| \geq \lambda_*, \quad g, h \in \mathfrak{h},
\end{equation}
holds for some constant \( C_{\ell} = C_{\ell}(q, \bar{q}) \) which is independent of \( \lambda \).

Let us now consider two functions \( G \in \mathcal{G} \) and \( H \in \mathcal{G} \), that will be made precise below, and put \( u := (A - \lambda)^{-1}(\Delta - q + \lambda)G + G, \ g := \partial_\nu G + \alpha G|_\Gamma \) and \( h :=
\( \partial_n R + \alpha R \big|_\Gamma \). Then, bearing in mind that \( \partial_n u + u \big|_\Gamma = g \), the Green formula yields that
\[
\int_\Gamma u \partial_t ds(x) = \int_\Gamma g \partial_t ds(x) + \int_\Omega (u \Delta R - \Delta u R) dx.
\]
Further, taking into account that \( \Delta u = (q - \lambda)u \) in \( \Omega \), we see that
\[
u R = \Delta u R = \Delta u - (q - \lambda)u R = (A - \lambda)^{-1}(\Delta - q + \lambda)G + G (\Delta - q + \lambda) R.
\]
Thus, assuming that \( (\Delta + \lambda)G = (\Delta + \lambda)R = 0 \), the above identity reduces to
\[
u R = - (A - \lambda)^{-1}qG + G R,
\]
and (3.3) then reads
\[
\int_\Gamma u \partial_t ds(x) = \int_\Gamma g \partial_t ds(x) - \int_\Omega (A - \lambda)^{-1}qG + G R dx.
\]
This being said, we set \( \lambda = (\tau + i)^2 \) for some fixed \( \tau \in [1, +\infty) \), pick two vectors \( \omega \) and \( \theta \) in \( \mathbb{S}^{n-1} \), and we consider the special case where
\[
G(x) = e_{\lambda, \omega}(x) := e^{i \sqrt{\lambda} \omega \cdot x}, \quad R(x) = e_{\lambda, -\omega}(x) := e^{-i \sqrt{\lambda} \theta \cdot x}.
\]
Next, we put
\[
S(\lambda, \omega, \theta) := \int_\Gamma u \partial_t ds(x), \quad S(\lambda, \omega, \theta) := \int_\Gamma \tilde{u} \partial_t ds(x),
\]
in such a way that
\[
S(\lambda, \omega, \theta) - \tilde{S}(\lambda, \omega, \theta) = \langle R^\lambda_{\lambda_\omega}(g), h \rangle.
\]
Then, taking into account that
\[
g(x) = (i \sqrt{\lambda} \omega \cdot \nu + \alpha)e^{i \sqrt{\lambda} \omega \cdot x}, \quad \tilde{h}(x) = (\sqrt{\lambda} \theta \cdot \nu + \alpha)e^{-i \sqrt{\lambda} \theta \cdot x},
\]
we have \( ||g||_{L^2(\Gamma)} ||h||_{L^2(\Gamma)} \leq C \tau^2 \) for some positive constant \( C \) which is independent of \( \omega \), \( \theta \) and \( \tau \), and we infer from (3.2) and (3.5) that
\[
\lim_{\tau \to +\infty} \sup_{\omega, \theta \in \mathbb{S}^{n-1}} \langle S(\lambda, \omega, \theta) - \tilde{S}(\lambda, \omega, \theta) \rangle = 0.
\]
On the other hand, (3.4) reads
\[
S(\lambda, \omega, \theta) = S_0(\lambda, \omega, \theta) + \int_\Gamma (i \sqrt{\lambda} \omega \cdot \nu + \alpha)e^{-i \sqrt{\lambda} \theta \cdot \omega \cdot x} ds(x),
\]
where
\[
S_0(\lambda, \omega, \theta) := \int_\Omega (A - \lambda)^{-1}(q e_{\lambda, \omega} q e_{\lambda, -\theta} dx - \int_\Omega q e^{-i \sqrt{\lambda} \theta \cdot \omega \cdot x} \omega \cdot \nu + \alpha) e^{-i \sqrt{\lambda} \theta \cdot x} dx.
\]
Now, we fix \( \xi \) in \( \mathbb{R}^n \), pick \( \eta \in \mathbb{S}^{n-1} \) such that \( \xi \cdot \eta = 0 \), and for all \( \tau \in (|\xi|/2, +\infty) \) we set
\[
\omega_\tau := (1 - |\xi|^2/(4\tau^2))^{1/2} \eta - \xi/(2\tau), \quad \theta_\tau := (1 - |\xi|^2/(4\tau^2))^{1/2} \eta + \xi/(2\tau)
\]
in such a way that
\[
\lim_{\tau \to +\infty} \sqrt{\lambda_\tau} (\theta_\tau - \omega_\tau) = \xi.
\]
Evidently, we have
\[
||e_{\lambda, \omega_\tau}||_{L^\infty(\Omega)} \leq ||e_{\xi}||_{L^\infty(\Omega)}, \quad ||e_{\lambda, -\theta_\tau}||_{L^\infty(\Omega)} \leq ||e_{\xi}||_{L^\infty(\Omega)}.
\]
Next, recalling that $\beta = \max(0, n(2 - r)/(2r))$, we see that $\beta = 0$ and hence $p_\beta = p_0 = 2$, when $n \geq 4$, whereas $p_\beta = r \in (3/2, 2)$, when $n = 3$. Thus, we have $p_\beta \leq r$ whenever $n \geq 3$, and consequently $q \in L^{p_\beta}(\Omega)$. It follows from this and (3.11) that $q\chi_{\lambda, \omega}$ and $q\chi_{\lambda, -\theta}$ lie in $L^{p_\beta}(\Omega)$ and satisfy the estimate
\begin{equation}
\|q\chi_{\lambda, \omega}\|_{L^{p_\beta}(\Omega)} + \|q\chi_{\lambda, -\theta}\|_{L^{p_\beta}(\Omega)} \leq C\|q\|_{L^r(\Omega)}, \quad \tau \in [\xi]/2, \infty),
\end{equation}
for some positive constant $C = C(n, \Omega)$ depending only on $n$ and $\Omega$. Moreover, for all $\tau \geq \max(|\xi|/2, \tau^*)$, we have
\begin{equation}
\left|\int_\Omega (A - \lambda)^{-1}(q\chi_{\lambda, \omega})q\chi_{\lambda, -\theta} \, dx\right| \\
\leq \|(A - \lambda)^{-1}(q\chi_{\lambda, \omega})\|_{L^{p_\beta}(\Omega)} \|q\chi_{\lambda, -\theta}\|_{L^{p_\beta}(\Omega)} \\
\leq C\tau^{-1+2\beta} \parallel q\chi_{\lambda, \omega} \parallel_{L^{p_\beta}(\Omega)} \parallel q\chi_{\lambda, -\theta} \parallel_{L^{p_\beta}(\Omega)},
\end{equation}
by (2.12), where $C > 0$ is independent of $\tau$. Since $\beta \in [0, 1/2)$ from its definition in Theorem 1.2, we infer from (3.12)-(3.13) that
\begin{equation}
\lim_{\tau \to \infty} \left|\int_\Omega (A - \lambda)^{-1}(q\chi_{\lambda, \omega})q\chi_{\lambda, -\theta} \, dx\right| = 0,
\end{equation}
which together with (3.8)-(3.10) yields that
\begin{equation}
\lim_{\tau \to \infty} S_0(\lambda, \omega, \theta, \tau) = -\int_\Omega q e^{-i\xi \cdot x}, \quad \xi \in \mathbb{R}^n.
\end{equation}
From this and the identity
\begin{equation}
\lim_{\tau \to \infty} (S_0(\lambda, \omega, \theta, \tau) - \tilde{S}_0(\lambda, \omega, \theta, \tau)) = \lim_{\tau \to \infty} (S(\lambda, \omega, \theta, \tau) - \tilde{S}(\lambda, \omega, \theta, \tau)) = 0,
\end{equation}
arising from (3.6)-(3.7), it then follows that
\begin{equation}
\int_\Omega (q - \tilde{q}) e^{-i\xi \cdot x} \, dx = 0, \quad \xi \in \mathbb{R}^n.
\end{equation}
Otherwise stated, the Fourier transform of $(q - \tilde{q})\chi_\Omega$, where $\chi_\Omega$ is the characteristic function of $\Omega$, is identically zero in $\mathcal{S}'(\mathbb{R}^n)$. By the injectivity of the Fourier transformation, this entails that $q = \tilde{q}$ in $\Omega$.

3.2. **Proof of Theorem 1.2.** Pick $\omega$ and $\theta$ be in $\mathbb{S}^{n-1}$, and let $\lambda \in \mathbb{C} \setminus \mathbb{R}$. We use the same notations as in the proof of Theorem 1.1. Namely, for all $x \in \Gamma$, we write
\begin{equation}
g(x) = g_\lambda(x) = (i\sqrt{\lambda \omega} \cdot \nu + \alpha) e^{iv\sqrt{\lambda \omega} x}, \quad \tilde{g}(x) = \tilde{g}_\lambda(x) = (-i\sqrt{-\lambda \theta} \cdot \nu + \alpha) e^{-iv\sqrt{-\lambda \theta} x},
\end{equation}
and we recall that $S(\lambda, \omega, \theta) = \int_\Gamma u_\lambda(g) \tilde{g} \, ds(x)$. Next, for all $\mu \in \rho(A) \cap \rho(\tilde{A})$ we set
\begin{equation}
T(\lambda, \mu) = T(\lambda, \mu, \omega, \theta) := S(\lambda, \omega, \theta) - S(\mu, \omega, \theta) = \int_\Gamma (u_\lambda(g) - u_\mu(g)) \tilde{g} \, ds(x).
\end{equation}
By Lemma 2.3, we have
\begin{equation}
T(\lambda, \mu) = (\lambda - \mu) \sum_{k \geq 1} \frac{d_k}{(\lambda_k - \lambda)(\lambda_k - \mu)}, \quad d_k := (g, \psi_k)(\psi_k, h),
\end{equation}
and hence
\begin{equation}
T(\lambda, \mu) - \tilde{T}(\lambda, \mu) = U(\lambda, \mu) + V(\lambda, \mu),
\end{equation}
where

\begin{align}
U(\lambda, \mu) &:= \sum_{k \geq 1} \frac{\lambda - \mu}{\lambda_k - \mu} \frac{d_k - \tilde{d}_k}{\lambda_k - \lambda}, \\
V(\lambda, \mu) &:= \sum_{k \geq 1} \left( \frac{\lambda - \mu}{(\lambda_k - \lambda)(\lambda_k - \mu)} - \frac{\lambda - \mu}{(\lambda_k - \lambda)(\lambda_k - \mu)} \right) d_k.
\end{align}

Notice that for all \( k \in \mathbb{N} \), we have \( d_k - \tilde{d}_k = (g, \psi_k - \tilde{\psi}_k)(\psi_k, h) + (g, \tilde{\psi}_k)(\psi_k - \tilde{\psi}_k, h) \), which immediately entails that

\begin{equation}
\frac{|d_k - \tilde{d}_k|}{|\lambda_k - \lambda|} \leq \left( \frac{|(g|\psi_k)|}{|\lambda_k - \lambda|} \|h\|_{L^2(\Gamma)} + \rho_k(\lambda) \frac{|(\tilde{\psi}_k|h)|}{|\lambda_k - \lambda|} \|g\|_{L^2(\Gamma)} \right) \|\psi_k - \tilde{\psi}_k\|_{L^2(\Gamma)},
\end{equation}

where \( \rho_k(\lambda) := |\tilde{\lambda}_k - \lambda|/|\lambda_k - \lambda| \). Further, since \( 0 \leq \rho_k(\lambda) \leq 1 + |\lambda_k - \tilde{\lambda}_k|/|\lambda_k - \lambda| \) and \( (\lambda_k - \tilde{\lambda}_k) \in \ell^\infty \) by assumption, with \( \| (\lambda_k - \tilde{\lambda}_k)\|_{\ell^\infty} \leq N \), it is apparent that \( \rho_k(\lambda) \in \ell^\infty \) and that

\[ \| (\rho_k(\lambda))\|_{\ell^\infty} \leq \zeta(\lambda) := 1 + \frac{N}{|3\lambda|}. \]

Thus, applying the Cauchy-Schwarz inequality in (3.19) and Parseval’s theorem to the representation formula (2.15) in Lemma 2.2, we get that

\begin{equation}
\sum_{k=1}^{N} \frac{|d_k - \tilde{d}_k|}{|\lambda_k - \lambda|} \leq M(\lambda) \| (\psi_k - \tilde{\psi}_k)\|_{\ell^2(\Gamma)}, \quad N \in \mathbb{N},
\end{equation}

where

\begin{equation}
M(\lambda) := \|h\|_{L^2(\Gamma)} \|u_\lambda(g)\|_H + \zeta(\lambda) \|g\|_{L^2(\Gamma)} \|\tilde{u}_\lambda(h)\|_H.
\end{equation}

As a consequence we have \( \sum_{k \geq 1} |d_k - \tilde{d}_k|/|\lambda_k - \lambda| < \infty \). Furthermore, taking into account that

\[ \frac{|\lambda - \mu|}{|\lambda_k - \mu|} \leq 1 + \frac{|\lambda|}{\lambda_1}, \quad \mu \in (-\infty, -\lambda_1], \]

we apply the dominated convergence theorem to (3.17) and find that

\begin{equation}
\lim_{\mu \to -\infty} U(\lambda, \mu) = \sum_{k \geq 1} \frac{\lambda_k - \lambda}{\lambda_k - \lambda} \frac{d_k - \tilde{d}_k}{\lambda_k - \lambda} =: U(\lambda).
\end{equation}

Moreover, we have

\begin{equation}
|U(\lambda)| \leq M(\lambda) \| (\psi_k - \tilde{\psi}_k)\|_{\ell^2(\Gamma)},
\end{equation}

according to (3.20).

Arguing as before with \( V \) defined by (3.18) instead of \( U \), we obtain in a similar fashion that

\begin{equation}
\lim_{\mu \to -\infty} V(\lambda, \mu) = \sum_{k \geq 1} \frac{\tilde{\lambda}_k - \lambda_k}{(\lambda_k - \lambda)(\tilde{\lambda}_k - \lambda)} \tilde{d}_k =: V(\lambda)
\end{equation}

and that

\begin{equation}
|V(\lambda)| \leq \zeta(\lambda) \| (\tilde{\lambda}_k - \lambda_k)\|_{\ell^\infty} \|u_\lambda(g)\|_H \|\tilde{u}_\lambda(h)\|_H.
\end{equation}
Having seen this, we refer to (3.15)-(3.16) and deduce from Lemma 2.5, (3.22) and (3.24) that

\[
\int_\Gamma (u_\lambda (g) - \tilde{u}_\lambda (g)) \bar{\varphi} ds(x) = \mathcal{U}(\lambda) + \mathcal{V}(\lambda).
\]

Now, taking \( \lambda = \lambda_\tau = (\tau + i)^2 \) for some fixed \( \tau \in (|\xi|/2, \infty) \) and \( (\omega, \theta) = (\omega_\tau, \theta_\tau) \), where \( \omega_\tau \) and \( \theta_\tau \) are the same as in (3.9), we combine (3.7)-(3.8) with (3.26). We obtain that the Fourier transform \( \hat{b} \) of \( b := (\tilde{q} - q)\chi_\Omega \), reads

\[
\hat{b}(1 + i/\tau) = \mathcal{U}(\lambda_\tau) + \mathcal{V}(\lambda_\tau) + \Re(\lambda_\tau),
\]

where \( \Re(\lambda_\tau) := \int_\Omega (\hat{A} - \lambda_\tau)^{-1}(\hat{q}\xi_{\lambda_\tau, \omega_\tau}) \hat{q}\xi_{\lambda_\tau, -\theta_\tau} dx - \int_\Omega (A - \lambda_\tau)^{-1}(q\xi_{\lambda_\tau, \omega_\tau})q\xi_{\lambda_\tau, -\theta_\tau} dx. \)

Moreover, for all \( \tau \geq \max(|\xi|/2, \tau^*) \), we have

\[
|\Re(\lambda_\tau)| \leq C\tau^{-1+2\beta},
\]

by (3.12)-(3.13), where \( \beta \in [0, 1/2] \) is defined in Theorem 1.2 and \( \tau^* \) is the same as in Corollary 2.1. Here and in the remaining part of this proof, \( C \) denotes a positive constant depending only on \( n, \Omega, \Re \) and \( c \), which may change from line to line.

On the other hand, using that

\[
|\hat{b}(1 + i/\tau)| \approx |\hat{b}((1 + i/\tau)\xi)| = \left| \int_{\mathbb{R}^n} e^{-i\xi \cdot x} \left( e^{i\xi \cdot x} - 1 \right) b(x) dx \right| \leq \frac{|\xi|}{\tau} \left( \sup_{x \in \Omega} \left| e^{i(|\xi|/\tau) |x|} \right| \right) \|b\|_{L^1(\mathbb{R}^n)},
\]

we get in a similar way to [8, Eq. (5.1)] that

\[
|\hat{b}(\xi)| \leq |\hat{b}((1 + i/\tau)\xi)| + C|\xi| e^{c|\xi|/\tau N}, \quad \tau \in (|\xi|/2, \infty),
\]

for some positive constant \( c \) depending only on \( \Omega \). Putting this together with (3.27)-(3.28) we find that for all \( \tau \geq \max(|\xi|/2, \tau^*) \),

\[
|\hat{b}(\xi)| \leq \frac{C}{\tau^{1-\beta}} + \frac{c|\xi|}{\tau} e^{c|\xi|/\tau N} + \|\mathcal{U}(\lambda_\tau)\| + \|\mathcal{V}(\lambda_\tau)\|.
\]

To upper bound \( |\mathcal{U}(\lambda_\tau)| + |\mathcal{V}(\lambda_\tau)| \) on the right hand side of (3.29), we recall from (2.14) that \( u_\lambda_\tau(g) = -(A - \lambda_\tau)^{-1}(q\xi_{\lambda_\tau, \omega_\tau}) + c_{\lambda_\tau, \omega_\tau} \) and that \( \tilde{u}_\lambda_\tau(h) = -(\hat{A} - \lambda_\tau)^{-1}(\hat{q}\xi_{\lambda_\tau, -\theta_\tau}) + c_{\lambda_\tau, -\theta_\tau} \), and we combine (2.12) with (3.11) and (3.12): We get for all \( \tau \geq \tau_\xi := \max(1, |\xi|/2, \tau^*) \), that

\[
\|u_\lambda_\tau(g)\|_H + \|\tilde{u}_\lambda_\tau(h)\|_H \leq C.
\]

This together with the basic estimate \( \|g\|_{L^2(\Gamma)} + \|h\|_{L^2(\Gamma)} \leq C\tau, \) (3.21), (3.23) and (3.25), yield that

\[
|\mathcal{U}(\lambda_\tau)| + |\mathcal{V}(\lambda_\tau)| \leq C \left( \tau \|e(\psi_k - \tilde{\psi}_k)\|_{L^2(\Gamma)} + \|e(\tilde{\lambda}_k - \lambda_k)\|_{\ell^\infty} \right), \quad \tau \in [\tau_\xi, \infty).
\]

Inserting this into (3.29), we find that

\[
|\hat{b}(\xi)| \leq \frac{C}{\tau^{1-\beta}} + \frac{c|\xi|}{\tau} e^{c|\xi|/\tau N} + C\tau \delta, \quad \tau \in [\tau_\xi, \infty),
\]

where we have set

\[
\delta := \|e(\psi_k - \tilde{\psi}_k)\|_{L^2(\Gamma)} + \|e(\tilde{\lambda}_k - \lambda_k)\|_{\ell^\infty}.
\]
Let $\tau \in (0, \infty)$, where $\tau^*$ is defined in Corollary 2.1, it is apparent that the condition $\tau \geq \tau_0$ is automatically satisfied whenever $\xi \in B(0, \tau^0) := \{ \xi \in \mathbb{R}^n, |\xi| < \tau^0 \}$. Thus, squaring both sides of (3.30) and integrating the obtained inequality over $\bigcup_{i=0}^{\tau^0} H \setminus B(0, \tau^0)$, we get that
\[
\| \hat{b} \|^2_{\mathbb{L}^2(B(0, \tau^0))} \leq C \left( \tau^{-2(1-2\beta)+\delta n} + e^{\tau^{-1-\delta}} \tau^{2(2+n)} \right), \quad \tau \in [\tau^*, \infty),
\]
and then taking $\tau = (1-2\beta)/(2+n)$, we obtain that
\[
(3.31) \quad \| \hat{b} \|^2_{\mathbb{L}^2(B(0, \tau^*(1-2\beta)/(2+n)))} \leq C \left( \tau^{-2(1-2\beta)}/(2+n) + \tau^{(3\delta+4)/(n+2)} \delta^2 \right), \quad \tau \in [\tau^*, \infty).
\]
On the other hand, using that the Fourier transform is an isometry from $L^2(\mathbb{R}^n)$ to itself, we have for all $\tau \in [\tau^*, \infty)$,
\[
\int_{\mathbb{R}^n \setminus B(0, \tau^*(1-2\beta)/(2+n))} (1+|\xi|^2)^{-1} |\hat{b}(\xi)|^2 d\xi \leq \tau^{-2(1-2\beta)/(2+n)} \| \hat{b} \|^2_{\mathbb{L}^2(\mathbb{R}^n)} \leq C \tau^{-2(1-2\beta)/(2+n)},
\]
which together with (3.31) yields that
\[
\| b \|^2_{\mathbb{L}^{1}(\mathbb{R}^n)} \leq \tau^{-2(1-2\beta)/(2+n)} + \tau^{(4+3\delta)/(n+2)} \delta^2, \quad \tau \in [\tau^*, \infty).
\]
Assuming that $\delta < (2(1-2\beta)/(4+3n))^{1/2} =: \delta_0$, we get by minimizing the right hand side of the above estimate with respect to $\tau \in [\tau^*, \infty)$, that
\[
\| b \|^2_{\mathbb{L}^{1}(\mathbb{R}^n)} \leq C \delta^{2(1-2\beta)/(3(2+n))},
\]
and the desired stability inequality follows from this upon recalling that $\| q - \tilde{q} \|^2_{\mathbb{L}^{1}(\Omega)} \leq \| b \|^2_{\mathbb{L}^{1}(\mathbb{R}^n)}$. Finally, we complete the proof by noticing that for all $\delta \geq \delta_0$, we have
\[
\| q - \tilde{q} \|^2_{\mathbb{L}^{1}(\Omega)} \leq \| q - \tilde{q} \|^2_{\mathbb{L}^{1}(\Omega)} \leq \left( 2N \delta_0^{-2(1-2\beta)/(3(2+n))} \right) \delta^{2(1-2\beta)/(3(2+n))}.
\]
