Radiative cooling of $\text{H}_3\text{O}^+$ and its deuterated isotopologues†

Vladlen V. Melnikov,a Sergei N. Yurchenko,*b Jonathan Tennysonb and Per Jensen†c

In conjunction with ab initio potential energy and dipole moment surfaces for the electronic ground state, we have made a theoretical study of the radiative lifetimes for the hydronium ion $\text{H}_3\text{O}^+$ and its deuterated isotopologues. We compute the ro-vibrational energy levels and their associated wavefunctions together with Einstein coefficients for electric dipole transitions. A detailed analysis of the stability of the ro-vibrational states has been carried out and the longest-living states of the hydronium ions have been identified. We report estimated radiative lifetimes and cooling functions for temperatures <200 K. A number of long-living meta-stable states are identified, capable of population trapping.

1 Introduction

In the Universe, molecules are found in a wide variety of environments: from diffuse interstellar clouds at very low temperatures to the atmospheres of planets, brown dwarfs and cool stars which are significantly hotter. In order to describe the evolution of the diverse, complex environments, it is essential to have realistic predictions of the radiative and cooling properties of the constituent molecules. Such predictions, in turn, require reasonable models for the energetics of each molecular species present.

Although interstellar molecular clouds are usually characterised as cold, they are mostly not fully thermalized. Whether a species attains thermal equilibrium with the environment depends on the radiative lifetimes of its states and the rate of collisional excitations to the states: this is normally characterised by the critical density. In non-thermalized regions, radiative lifetimes are also important for modelling the maser activity observed for many species. The long lifetimes associated with certain excited states can lead to population trapping and non-thermal, inverted distributions. Such unexpected state distributions have been observed for the $\text{H}_3^+$ molecule both in space1,2 and in the laboratory.3,4

Dissociative recombination of hydronium $\text{H}_2\text{O}^+$ has been extensively studied in ion storage rings.5–9 The lifetimes calculated in the present work suggest that $\text{H}_3\text{O}^+$ and its isotopologues will exhibit population trapping in a manner similar to that observed for $\text{H}_3^+$ in storage rings. Dissociative recombination of hydronium has been postulated as a possible cause of emissions from super-excited water in cometary comae10 and as the mechanism for a spontaneous infrared water laser.11

Hydronium and its isotopologues play an important role in planetary and interstellar chemistry.7,12 These molecular ions are found to exist abundantly in both diffuse and dense molecular clouds as well as in comae. Moreover, $\text{H}_3\text{O}^+$ is a water indicator and can be used to estimate water abundances when direct detection is unfeasible.13 Consequently, the ions have been the subject of numerous theoretical and experimental studies (see, for example, ref. 7, 8, 12–46 and references therein) mainly devoted to the spectroscopy and chemistry of the species.

Whereas the cooling function of the $\text{H}_3^+$ ion has been extensively studied by Miller et al.,47–49 no information about the radiative and cooling properties of $\text{H}_3\text{O}^+$ and its deuterated isotopologues has been available thus far. In the present work, we remedy this situation by determining theoretically the ro-vibrational states of the ions $\text{H}_3\text{O}^+$, $\text{H}_2\text{DO}^+$, $\text{HD}_2\text{O}^+$, and $\text{D}_3\text{O}^+$. We use ab initio potential energy (PES) and dipole moment surfaces (DMS) for the ground electronic states of $\text{H}_2\text{O}^+$ from ref. 50 to compute for each of the four ions considered here, ro-vibrational energy levels, the accompanying wavefunctions, and Einstein coefficients for the relevant ro-vibrational (electric dipole) transitions by means of the nuclear-motion program TROVE.51 Lifetimes of individual ro-vibrational states are calculated and analyzed together with the overall cooling rates. Recently, the same methodology was used to estimate the sensitivities of hydronium-ion transition frequencies to a possible time variation of the proton-to-electron mass ratio.52

We present a detailed analysis of the stability of the ro-vibrational states of the hydronium ions and identify the states with the longest lifetimes. This study is based on the methodology developed very recently as part of the ExoMol project.53

The ExoMol project aims at a comprehensive description of the spectroscopic properties of molecules important for atmospheres of exoplanets and cool stars. The molecular lifetimes and cooling functions determined for H$_3$O$^+$ and its deuterated isotopologues in the present work are available in the new ExoMol data format.$^{54}$

2 Theory and computation

The ro-vibrational energy levels and wavefunctions of the ions under study were calculated variationally using the TROVE program,$^{51,55}$ in a manner similar to the successful calculations previously carried out for several other XY$_3$ pyramidal molecules$^{56-61}$ including ammonia NH$_3$ (see ref. 62 and 63), which exhibits the same large-amplitude, ‘umbrella-flipping’ inversion motion as H$_3$O$^+$. The inversion barrier of H$_3$O$^+$ is 650.9 cm$^{-1},^{64}$ which is lower than 1791 cm$^{-1}$ for NH$_3$.$^{39}$ As a result, H$_3$O$^+$ inversion splitting of the ro-vibrational ground state, 55.35 cm$^{-1}$ (ref. 65), is significantly larger than 0.793 cm$^{-1}$ (ref. 39) of NH$_3$.

We have used ab initio PES and DMS of H$_3$O$^+$ (ref. 50), computed at the MRCI/aug-cc-pwCV5Z(5Z) and MRCI/aug-cc-pwCVQZ(QZ) levels of theory, respectively. Complete basis set (CBS) extrapolation was used to obtain the Born–Oppenheimer PES (see ref. 50 for details).

The basis set used in the variational computations of the ro-vibrational states is defined in ref. 51. In all calculations of the PES (see ref. 50 for details). The ro-vibrational energy levels and wavefunctions of the ions under study were calculated variationally using the TROVE scheme$^{66}$) for the bending vibrations. The ab initio equilibrium structure of H$_3$O$^+$ is characterized by an O–H bond length of 0.9758 Å and a H–O–H angle of 111.95$^\circ$.$^{3}$ The vibrational basis set is controlled by the polyad number by

$$P = 2(v_1 + v_2 + v_3) + v_4 + v_5 + v_6/2,$$

where $v_1, v_2, v_3$ represent the quanta of the stretching motion, $v_4$ and $v_5$ are those of the asymmetric bending motion and $v_6$ is that of the primitive basis set functions for the inversion. In the present work, the maximum polyad number $P_{\text{max}}$ (where $P < P_{\text{max}}$) was set to 28. The ro-vibrational basis sets used for H$_3$O$^+$ and D$_2$O$^+$ were symmetrized according to the $G_{3h}(M)$ molecular symmetry group$^{67}$ while the calculations for the asymmetric isotopologues H$_2$D$^+$ and HD$_2$O$^+$ were done under the $G_{2h}(M)$ symmetry. The computational details of the basis set construction can be found in ref. 62 as well as the details of the calculations of the Einstein coefficients $A_f$. The latter were computed for all possible initial, $i$, and final, $f$, states lying less than 600 cm$^{-1}$ above the zero point energy with $f \leq 7$. According to our estimations, this should be sufficient to describe the populations of the ro-vibrational states at thermodynamic temperatures up to 200 K. In this work we concentrate on the low energy applications. Higher temperatures would require higher rotational excitations $f$ and therefore more involved calculations.

The lifetimes of the states were computed as$^{52}$

$$\tau_i = \frac{1}{\sum_f A_{if}},$$

where the summation is taken over all possible final states $f$ with energies lower than that of the given initial state $i$. The Einstein coefficients (in units of $s^{-1}$) are defined as follows.$^{68}$

$$A_{if} = \frac{64\pi^2\hbar^3}{3h(2J_f + 1)} \sum_{m,m'} \sum_{A,X,Y,Z} |\langle \Psi_f | \mu_A | \Psi_i \rangle|^2,$$

where $h$ is Planck’s constant, $\nu_f$ (cm$^{-1}$) is the wavenumber of the line, $(h\nu_f E_f - E_i)J_f$ is the rotational quantum number for the final state, $\Psi_f$ and $\Psi_i$ represent the ro-vibrational eigenfunctions of the final and initial states, respectively, $m_i$ and $m_f$ are the corresponding projections of the total angular momentum on the $z$ axis, and $\mu_A$ is the electronically averaged component of the dipole moment (Debye) along the space-fixed axis $A = X, Y, Z$ (see also ref. 69).

The cooling function $W(T)$ is the total power per unit solid angle emitted by a molecule at temperature $T$; it is given by the following expression$^{52}$

$$W(T) = \frac{1}{4\pi Q(T)} \sum_{ij} A_{if} h\nu_f (2J_i + 1) g_i \exp \left( \frac{c_i E_i}{T} \right),$$

where $g_i$ is the nuclear spin statistical weight factor of the state $i$. In the Boltzmann factor exp$(-c_i E_i/T)$, $E_i (=E_i/hc)$ is the term for the ion $i$ of the ro-vibrational level $E_i$. We have calculated ro-vibrational terms of H$_3$O$^+$ and its deuterated isotopologues (in cm$^{-1}$) compared to theoretical values from the present work.

Table 1: Available, experimentally derived vibrational term values of H$_3$O$^+$ and its deuterated isotopologues (in cm$^{-1}$) compared to theoretical values from the present work.
value of state $i$ and $c_2 = \hbar c/k$ is the second radiation constant ($k$ is the Boltzmann constant). The partition function $Q(T)$ is defined as

$$Q(T) = \sum_i g_i (2J_i + 1) \exp \left( \frac{-c_2 E_i}{kT} \right).$$  \hspace{1cm} (5)

Partition functions were computed for each ion employing the sets of ro-vibrational energies obtained with the chosen basis set. The same PES and DMS were used for each isotopologue, which means that no allowance was made for the breakdown of the Born–Oppenheimer approximation. The energies of H$_3$O$^+$ and the three deuterated isotopologues are very different not only due to the mass changes, but also due to the different symmetries these species belong to and the ensuing nuclear spin statistics. We use the molecular symmetry group $D_3h(M)$ to classify the ro-vibrational states of the highest-symmetry species H$_3$O$^+$ and D$_3$O$^+$, and $C_{2v}(M)$ for the lower-symmetry isotopologues H$_2$DO$^+$ and HD$_2$O$^+$. The differences in the Einstein coefficients are also quite substantial, especially between the $D_{3h}(M)$ and the $C_{2v}(M)$ isotopologues. In general, isotope substitution in ions often leads to large changes in ro-vibrational intensities. This is because these intensities depend on the components of the electric dipole moment in the molecule-fixed axis system which, by definition, has its origin in the nuclear center-of-mass. Upon isotopic substitution, the center-of-mass, and thus the origin of the molecule-fixed axis system, are displaced. For a neutral molecule (i.e., a molecule with no net charge) this does not change the dipole moment components but, for an ion, they do (see, for example, ref. 70). Owing to intensities and Einstein coefficients changing much upon isotopic substitution, the lifetimes of the ro-vibrational states are expected to vary strongly with isotopologue for H$_3$O$^+$. Selection rules for $J$ are

$$J' - J'' = 0, \pm 1 \quad \text{and} \quad J' + J'' > 0. \hspace{1cm} (6)$$

The symmetry selection rules for H$_3$O$^+$ and D$_3$O$^+$ are

$$A'_{1} \leftrightarrow A''_{1}, \quad A'_{2} \leftrightarrow A''_{2}, \quad E' \leftrightarrow E''. \hspace{1cm} (7)$$

where, for H$_3$O$^+$ levels of $A'_{1}$ and $A''_{1}$ symmetry are missing so that the associated selection rule is irrelevant, while those for H$_2$DO$^+$ and HD$_2$O$^+$ are

$$A_1 \leftrightarrow A_3, \quad B_1 \leftrightarrow B_2. \hspace{1cm} (8)$$

Nuclear spin statistics$^{67}$ result in three distinct spin species of D$_3$O$^+$, ortho (ro-vibrational symmetry $A'_{1}$ or $A''_{1}$, nuclear spin...
The non-zero $z$-component is responsible for the parallel bands in the spectra of these species, including the rotation-inversion band\(^4\) (the pure rotation band is forbidden by symmetry). Botschwina et al.\(^18\) estimated the corresponding transition dipole for the inversion $0^- \leftrightarrow 0^+$ to be 1.47 D. Our \textit{ab initio} value is slightly higher, 1.80 D. For $\text{H}_2\text{DO}^+$ and $\text{HD}_2\text{O}^+$, the center-of-mass obviously is unchanged relative to $\text{H}_3\text{O}^+$ and $\text{D}_3\text{O}^+$ but the center-of-mass is shifted, and this produces a non-vanishing perpendicular dipole moment at $\mathcal{C}_{3v}$-symmetry geometries. If we take the $x$ axis to be in the plane defined by the $C_3$ symmetry axis and the O–H bond for $\text{HD}_2\text{O}^+$, and in the plane defined by the $C_3$ symmetry axis and the O–D bond for $\text{H}_2\text{DO}^+$, then $\text{H}_2\text{DO}^+$ and $\text{HD}_2\text{O}^+$ acquire non-vanishing $x$ dipole moment components. Therefore the perpendicular transitions ($\Delta K_z = \pm 1$) of $\text{H}_2\text{DO}^+$ and $\text{HD}_2\text{O}^+$ in the vibrational ground state are much stronger than the $\Delta K = \pm 1$ transitions of $\text{H}_3\text{O}^+$ and $\text{D}_3\text{O}^+$ which are caused by intensity stealing from the vibrational spectrum.\(^65\) Besides, this $x$ component is larger for $\text{HD}_2\text{O}^+$ than for $\text{H}_2\text{DO}^+$ owing to the greater displacement of the nuclear center-of-mass. This is probably why the $\text{HD}_2\text{O}^+$ lifetimes are shorter on the average than those of $\text{H}_2\text{DO}^+$. The $z$ dipole moment component also changes with isotopic substitutions, see Fig. 2.

| State | Term value, cm\(^{-1}\) | $\tau$ |

Table 2: Lifetimes $\tau$ for the longest-lived states of the $\text{H}_3\text{O}^+$, $\text{D}_3\text{O}^+$, $\text{H}_2\text{DO}^+$, and $\text{HD}_2\text{O}^+$ ions. All states listed are rotational states in the vibrational ground state (i.e., the inversion state $0^+$). The states are labeled $(J,K,Z)$ and $(J_{\kappa,K,Z})$ for $\mathcal{D}_{3h}(M)$ and $\mathcal{C}_{3v}(M)$ isotopologues, respectively, with $\kappa$ as the symmetry of the state in the respective group.
temperatures considered. Therefore, at moderate and high temperatures the lighter isotopologues are better coolers. However, Fig. 3 shows that at lower temperatures their roles change and the deuterated species become the better coolers. This is because the term values of the lowest, infinite-lifetime (and therefore coldest) states vary as 47.03 cm\(^{-1}\) \((J=2, K=2, E=0)\), 23.79 cm\(^{-1}\) \((J=2, K=0, E=0)\), 12.19 cm\(^{-1}\) \((J=1, K=2, E=0)\), and 11.69 cm\(^{-1}\) \((J=0, K=2, E=0)\) for \(\text{H}_3\text{O}^+\), \(\text{D}_3\text{O}^+\), \(\text{HD}_2\text{O}^+\), and \(\text{H}_2\text{DO}^+\), respectively. At very low temperatures, the molecules will tend to collect in the lowest accessible state, and the higher the term value of this state, the more difficult it is to cool the isotopologue in question. Because of this, for example, it is more difficult to cool \(\text{H}_3\text{O}^+\) than \(\text{D}_3\text{O}^+\) at temperatures below 30 K.

4 Conclusions

We have carried out a theoretical study of the ro-vibrational states of the hydronium ion \(\text{H}_3\text{O}^+\) and its deuterated isotopologues. \textit{Ab initio} potential energy and electric dipole moment surfaces were used to calculate ro-vibrational energy levels, corresponding wavefunctions and Einstein coefficients for the low-lying ro-vibrational transitions of these ions. We have analyzed the stability of the ro-vibrational states and computed the radiative lifetimes and cooling functions for temperatures below 200 K.

Taking into account only spontaneous emission as a cause of decay of ro-vibrational states (and neglecting collisions and stimulated emission) we find the longest-lived hydronium state for \(\text{D}_3\text{O}^+\): the population in the rotational state with \((J,K,E)=(5,5,E)\) is trapped for 3816.0 years, which is relatively ‘hot’ (152 K), at least in the context of molecular cooling, for example in storage rings. In this work we have identified a number of relatively hot \((E/k > 100 \text{ K})\) meta-stable states with a lifetime longer than 10 s (typical timescales of ion storage experiments). Such meta-stable states which will be populated and hamper the cooling of hydronium ions to a temperature of a few Kelvin. The molecule with the shortest-lived meta-stable states is \(\text{H}_2\text{DO}^+\) with lifetimes of a few days. The timescale of interstellar collisions in diffuse clouds is longer (about a month), and thus some of these states undergo spontaneous emission.

Our calculations show that deuteration influences significantly the hydronium lifetimes. This effect is mostly caused by the symmetry lowering from \(D_{3h}(M)\) to \(C_{3v}(M)\) and the ensuing perpendicular dipole moment component. A number of long-living meta-stable states are identified, capable of population trapping. Compared to the deuterated species, the cooling of the lightest isotopologue \(\text{H}_3\text{O}^+\) is most efficient at higher temperatures \((T > 30 \text{ K})\). However, this changes at very low temperatures where the \(\text{H}_3\text{O}^+\) ions are trapped at relatively high energy.

The results obtained can be used to assess the cooling properties of the hydronium ion in ion storage rings and elsewhere.
