AUTOMORPHISM GROUPS OF SUPEREXTENSIONS
OF FINITE MONOGENIC SEMIGROUPS

TARAS BANAKH AND VOLODYMYR GAVRYLIK

Abstract. A family \( \mathcal{L} \) of subsets of a set \( X \) is called linked if \( A \cap B \neq \emptyset \) for any \( A, B \in \mathcal{L} \). A linked family \( \mathcal{M} \) of subsets of \( X \) is maximal linked if \( \mathcal{M} \) coincides with each linked family \( \mathcal{L} \) on \( X \) that contains \( \mathcal{M} \). The superextension \( \lambda(X) \) of \( X \) consists of all maximal linked families on \( X \). Any associative binary operation \( \ast : X \times X \to X \) can be extended to an associative binary operation \( \ast : \lambda(X) \times \lambda(X) \to \lambda(X) \). In the paper we study automorphisms of the superextensions of finite monogenic semigroups and characteristic ideals in such semigroups. In particular, we describe the automorphism groups of the superextensions of finite monogenic semigroups of cardinality \( \leq 5 \).

1. Introduction

In this paper we investigate the automorphism group of the superextension \( \lambda(S) \) of a finite monogenic semigroup \( S \). The thorough study of various extensions of semigroups was started in [14] and continued in [1]–[10] and [15]–[18]. The largest among these extensions is the semigroup \( \upsilon(S) \) of subsets of a set \( X \) of non-empty subsets of \( S \). The semigroup \( \upsilon(S) \) is well-known in General and Categorial Topology as the \( \lambda \) (the cardinality of \( \sum_{\text{all } A} \{ A \in X \} \)) of all ultrafilters on a set \( X \) can be identified with each linked family \( \mathcal{L} \). A family \( \mathcal{L} \) is said to be linked if \( \mathcal{L} \) contains the family \( \sum_{\text{all } A} \{ A \in X \} \) of all maximal linked families on \( X \). Each point \( x \in X \) of \( \lambda(S) \) is identified with the principal ultrafilter \( \langle \{ x \} \rangle \) generated by the singleton \( \{ x \} \), and hence we can consider \( X \subset \lambda(S) \). It was shown in [14] that any associative binary operation \( \ast : S \times S \to S \) can be extended to an associative binary operation \( \ast : \upsilon(S) \times \upsilon(S) \to \upsilon(S) \) by the formula

\[
\sum_{\sum_{\text{all } A} \{ A \in X \}} a \ast B_a = \{ a \in A, \{ B_a \}_{a \in A} \subset B \}
\]

for upfamilies \( A, B \in \upsilon(S) \). In this case the Stone-Čech compactification \( \beta(S) \) is a subsemigroup of the semigroup \( \upsilon(S) \).

The semigroup \( \upsilon(S) \) contains as subsemigroups many other important extensions of \( S \). In particular, it contains the semigroup \( \lambda(S) \) of maximal linked upfamilies, see [13], [14]. An upfamily \( \mathcal{L} \) of subsets of \( S \) is said to be linked if \( \mathcal{L} \) contains the family \( \sum_{\text{all } A} \{ A \in X \} \) of all maximal linked families on \( X \). A linked upfamily \( \mathcal{M} \) of subsets of \( S \) is maximal linked if \( \mathcal{M} \) coincides with each linked upfamily \( \mathcal{L} \) on \( S \) that contains \( \mathcal{M} \). It follows that \( \beta(S) \) is a subsemigroup of \( \lambda(S) \). The space \( \lambda(S) \) is well-known in General and Categorial Topology as the superextension of \( S \), see [22]–[24].

For a finite set \( X \), the cardinality of the set \( \lambda(X) \) grows very quickly as \( |X| \) tends to infinity. The calculation of the cardinality of \( \lambda(X) \) seems to be a difficult combinatorial problem, which can be reformulated as the problem of counting the number \( \lambda(n) \) of self-dual monotone Boolean functions of \( n \) variables, which is well-known in Discrete Mathematics. According to Proposition 1.1 in [11],

\[
\log_2 \lambda(n) = \frac{2^n}{\sqrt{2\pi n}} + o(1),
\]

which means that the sequence \( (\lambda(n))_{n=1}^{\infty} \) has double exponential growth. The sequence of numbers \( \lambda(n) \) (known in Discrete Mathematics as Hösten-Morris numbers) is included in the On-line Encyclopedia of Integer Sequences as the sequence A001206. All known precise values of this sequence (taken from [11]) are presented in the following table.

| \( |X| \) | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
|---|---|---|---|---|---|---|---|---|---|
| \( |\lambda(X)| \) | 1 | 2 | 4 | 12 | 81 | 2646 | 1422564 | 229809982112 | 423295099074735261880 |

1991 Mathematics Subject Classification. 20D45, 20M15, 20B25.

Key words and phrases. monogenic semigroup, maximal linked upfamily, superextension, automorphism group.
Each map \( f : X \to Y \) induces the map 
\[ \lambda f : \lambda(X) \to \lambda(Y), \quad \lambda f : L \mapsto \langle f(L) \subset Y : L \in L \rangle, \]
see [13].

If \( \varphi : S \to S' \) is a homomorphism of semigroups, then \( \lambda \varphi : \lambda(S) \to \lambda(S') \) is a homomorphism as well, see [15].

A non-empty subset \( I \) of a semigroup \( S \) is called an ideal if \( IS \cup SI \subset I \). An ideal \( I \) of a semigroup \( S \) is called proper if \( I \neq S \). A proper ideal \( M \) of \( S \) is maximal if \( M \) coincides with each proper ideal \( I \) of \( S \) that contains \( M \). It is easy to see that for every \( n \in \mathbb{N} \) the subset \( S^n = \{ x_1 \cdots x_n : x_1, \ldots, x_n \in S \} \) is an ideal in \( S \).

An element \( z \) of a semigroup \( S \) is called a zero (resp. a left zero, a right zero) in \( S \) if \( az = za = z \) (resp. \( za = az = z \), \( az = z \)) for any \( a \in S \). An element \( e \) of a semigroup \( S \) is called an idempotent if \( ee = e \). By \( E(S) \) we denote the set of all idempotents of a semigroup \( S \).

Recall that an isomorphism between \( S \) and \( S' \) is a bijective function \( \psi : S \to S' \) such that \( \psi(xy) = \psi(x)\psi(y) \) for all \( x, y \in S \). If there exists an isomorphism between \( S \) and \( S' \), then \( S \) and \( S' \) are said to be isomorphic, denoted \( S \cong S' \). An isomorphism \( \psi : S \to S \) is called an automorphism of a semigroup \( S \). By \( \text{Aut}(S) \) we denote the automorphism group of a semigroup \( S \).

For an automorphism \( \psi \) of a semigroup \( S \), a subset \( A \subset S \) is called \( \psi \)-invariant if \( \psi(A) = A \). A subset \( A \subset S \) is called characteristic if \( \psi(A) = A \) for any automorphism \( \psi \) of \( S \). It is easy to see that the set \( E(S) \) is characteristic in \( S \) and so are the ideals \( S^n \) for all \( n \in \mathbb{N} \).

For a set \( X \) by \( S_X \) we denote the group of all bijections of \( X \). For two sets \( X \subset Y \) we shall identify \( S_X \) with the subgroup \( \{ \varphi \in S_Y : \varphi|Y \setminus X = \text{id} \} \). By \( C_n \) we denote a cyclic group of order \( n \in \mathbb{N} \).

In this paper we study automorphisms of superextensions of finite monogenic semigroups. The thorough study of automorphism groups of superextensions of semigroups was started in [19] and continued in [9]. In [19] it was shown that each automorphism of a semigroup \( S \) can be extended to an automorphism of its superextension \( \lambda(S) \) and the automorphism group \( \text{Aut}(\lambda(S)) \) of the superextension of a semigroup \( S \) contains a subgroup, isomorphic to the automorphism group \( \text{Aut}(S) \) of \( S \). Also it was described the automorphism groups of superextensions of null semigroups, almost null semigroups, right zero semigroups, left zero semigroups and all three-element semigroups. In [9] we studied the automorphism groups of superextensions of groups and described the automorphism groups \( \text{Aut}(\lambda(G)) \) of the superextensions of all groups \( G \) of cardinality \( |G| \leq 5 \). The obtained results are presented in Table 1.

| \( G \cong \) | \( C_1 \) | \( C_2 \) | \( C_3 \) | \( C_4 \) | \( C_2 \times C_2 \) | \( C_5 \) |
|----------------|--------|--------|--------|--------|-------------|--------|
| \( \text{Aut}(G) \cong \) | \( C_1 \) | \( C_1 \) | \( C_2 \) | \( C_2 \) | \( S_3 \) | \( C_4 \) |
| \( \text{Aut}(\lambda(G)) \cong \) | \( C_1 \) | \( C_1 \) | \( C_2 \) | \( C_2 \times C_2 \) | \( S_4 \) | \( C_4 \) |

**Table 1.** The automorphism groups of superextensions of groups of cardinality \( \leq 5 \)

## 2. Semigroups possessing a good shift

In this section we develop a tool for recognizing the automorphism group of a semigroup possessing a good shift.

**Definition 2.1.** Let \( X \) be a semigroup. A function \( \sigma : X \to X \) is called a good shift of \( X \) if \( X \cdot X \subset \sigma(X) \) and for any elements \( x, y \in X \) with \( \sigma(x) = \sigma(y) \) the equalities \( xx = yy \) and \( zx = zy \) hold for all \( z \in X \).

A good shift \( \sigma : S \to S \) is called an auto-shift if \( \sigma \circ \psi = \psi \circ \sigma \) for any automorphism \( \psi \in \text{Aut}(S) \).

**Proposition 2.2.** If \( \sigma : X \to X \) is a good shift of a semigroup \( X \), then the automorphism group \( \text{Aut}(X) \) of \( X \) contains the subgroup \( K \) consisting of all bijections \( \psi : X \to X \) of \( X \) such that \( \sigma \circ \psi = \sigma \) and \( \psi|XX = \text{id} \). This subgroup is isomorphic to \( \prod_{x \in \sigma(X)} S_{\sigma^{-1}(x) \setminus XX} \).

**Proof.** It is clear that the group \( K \) is isomorphic to the product of permutation groups \( \prod_{x \in \sigma(X)} S_{\sigma^{-1}(x) \setminus XX} \).

To see that \( K \subset \text{Aut}(X) \), it is necessary to check that each bijection \( \psi \in K \) is an automorphism of the semigroup \( X \). Given two elements \( x, y \in X \), we shall show that \( \psi(xy) = \psi(x) \cdot \psi(y) \). It follows that \( xy \in XX \) and hence \( \psi(xy) = xy \). Since \( \sigma \circ \psi = \sigma \), we obtain that \( \sigma(\psi(x)) = \sigma(x) \) and \( \sigma(\psi(y)) = \sigma(y) \). Now Definition 2.1 ensures that 
\[ \psi(x) \cdot \psi(y) = x \cdot y = xy = \psi(xy), \]
so \( \psi \in \text{Aut}(X) \). \( \square \)
A homomorphism $\rho : S \to S$ of a semigroup $S$ is called a homomorphic retraction if $\rho \circ \rho = \rho$. The functoriality of the superextension in the category of semigroups [15] ensures that for any homomorphic retraction $\rho : S \to S$ the map $\lambda \rho : \lambda(S) \to \lambda(S)$ is a homomorphic retraction, too.

For a semigroup $X$ by $\Xi_X$ denote the family of all characteristic subsets of $X$.

**Theorem 2.3.** If $\sigma : X \to X$ is an auto-shift of a semigroup $X$, then $\sigma(X)$ is a characteristic ideal of $X$ and for the restriction operator

$$ R : \text{Aut}(X) \to \text{Aut}(\sigma(X)), \quad R : \psi \mapsto \psi|\sigma(X), $$

the kernel of $R$ is equal to $\prod_{x \in \sigma(X)} S_{\sigma^{-1}(x)} \setminus \sigma(X)$ and $R(\text{Aut}(X)) \subset H \subset G$ where

$$ G = \{ \varphi \in \text{Aut}(\sigma(X)) \setminus \sigma(X) : \forall x \in \sigma(X) \varphi(\sigma^{-1}(x) \cap \sigma(x)) = \sigma^{-1}(\varphi(x)) \cap \sigma(x) \text{ and } |\sigma^{-1}(x) \setminus \sigma(X)| = |\sigma^{-1}(\varphi(x)) \setminus \sigma(X)| \} $$

and

$$ H := \{ \varphi \in G : \forall C \in \Xi_X \forall x \in \sigma(X) |\sigma^{-1}(x) \cap C| = |\sigma^{-1}(\varphi(x)) \cap C| \}. $$

If the auto-shift $\sigma$ is a homomorphic retraction, then $R(\text{Aut}(X)) = H = G$.

**Proof.** Definition 2.1 ensures that $XX \subset \sigma(X)$, so $\sigma(X)$ is an ideal in $X$. Since $\sigma$ is an auto-shift, for any automorphism $\psi \in \text{Aut}(X)$ we have $\psi \circ \sigma = \sigma \circ \psi$ and hence

$$ \psi(\sigma(x)) = \psi \circ \sigma(x) = \sigma \circ \psi(x) = \sigma(x), $$

which means that the ideal $\sigma(X)$ is characteristic in $X$.

Now consider the group $K$ of all bijections $\psi : X \to X$ such that $\sigma \circ \psi = \sigma$ and $\psi|\sigma(X)$ is the identity map of $\sigma(X)$. It is clear that the group $K$ is isomorphic to the product of permutation groups $\prod_{x \in \sigma(X)} S_{\sigma^{-1}(x)} \setminus \sigma(X)$. By Proposition 2.2, $K \subset \text{Aut}(X)$.

It is clear that $K$ is contained in the kernel Ker$(R)$ of the restriction operator $R : \text{Aut}(X) \to \text{Aut}(\sigma(X))$. On the other hand, for any automorphism $\psi \in \text{Ker}(R)$ we get $\sigma \circ \psi = \psi \circ \sigma = \sigma$, so $\psi \in K$.

Observe that for any automorphism $\psi$ of $X$ the equality $\psi^{-1} \circ \sigma = \sigma \circ \psi^{-1}$ implies that $\sigma^{-1}(y) = \sigma^{-1}(\psi(y))$ for any $y \in \sigma(X)$. Moreover, for any characteristic set $C \in \Xi_X$ we get $\psi(C) = C$ and hence

$$ \psi(\sigma^{-1}(x) \cap C) = \psi(\sigma^{-1}(x)) \cap \psi(C) = \sigma^{-1}(\psi(x)) \cap C $$

and hence $|\sigma^{-1}(x) \cap C| = |\sigma^{-1}(\psi(x)) \cap C|$. Since $\sigma(X) \in \Xi_X$, for the restriction $\varphi := \psi|\sigma(X)$ of $\psi$ we get $\varphi(\sigma^{-1}(x) \cap \sigma(X)) = \sigma^{-1}(\varphi(x)) \cap \sigma(X)$ for every $x \in \sigma(X)$, which means that $\varphi = R(\psi) \in H$ and hence $R(\text{Aut}(X)) \subset H$.

The inclusion $H \subset G$ follows from $X \setminus \sigma(X) \in \Xi_X$.

Assuming that $\sigma$ is a homomorphic retraction, we shall prove that $R(\text{Aut}(X)) = H = G$. It suffices to check that each automorphism $\varphi \in G$ extends to an automorphism of the semigroup $X$. By the definition of $G$, we can extend the automorphism $\varphi$ of $\sigma(X)$ to a bijection $\bar{\varphi}$ of $X$ such that $\bar{\varphi}(\sigma^{-1}(x) \setminus \sigma(X)) = \sigma^{-1}(\varphi(x)) \setminus \sigma(X)$ for all $x \in \sigma(X)$. By $\varphi \in G$, we also get $\varphi(\sigma^{-1}(x)) \cap \sigma(X) = \sigma^{-1}(\varphi(x)) \cap \sigma(X)$. So, $\varphi(\sigma^{-1}(x)) = \sigma^{-1}(\varphi(x))$ for any $x \in \sigma(X)$. This equality implies the equality $\sigma \circ \varphi = \varphi \circ \sigma$. Indeed, for any $z \in X$ and $x = \sigma(z)$ we get $\bar{\varphi}(z) = \bar{\varphi}(\sigma^{-1}(x)) = \sigma^{-1}(\varphi(x))$. Applying to this equality the map $\sigma$, we obtain $\sigma \circ \bar{\varphi}(z) = \varphi(\sigma(z))$ and hence $\sigma \circ \bar{\varphi}(z) = \varphi(z) = \sigma \circ \sigma(z)$.

Let us show that the bijection $\bar{\varphi}$ is an automorphism of $X$. Given any elements $x, y \in X$, it suffices to check that $\bar{\varphi}(xy) = \bar{\varphi}(x) \cdot \bar{\varphi}(y)$. Taking into account that $xy \in XX \subset \sigma(X)$ and $\sigma : X \to \sigma(X)$ is a homomorphic retraction, we conclude that $xy = \sigma(xy) = \sigma(x) \cdot \sigma(y)$ and thus

$$ \bar{\varphi}(xy) = \varphi(xy) = \varphi(\sigma(xy)) = \varphi(\sigma(x)) \cdot \varphi(\sigma(y)) = \sigma(\varphi(x)) \cdot \sigma(\varphi(y)) = \bar{\varphi}(x) \cdot \varphi(y). $$

\[\square\]

3. AUTOMORPHISMS AND CHARACTERISTIC IDEALS OF SUPEREXTENSIONS OF FINITE MONOGENIC SEMIGROUPLS

A semigroup $S$ is called monogenic if it is generated by some element $a \in S$ in the sense that $S = \{a^n : n \in \mathbb{N}\}$. If a monogenic semigroup is infinite, then it is isomorphic to the additive semigroup $\mathbb{N}$ of positive integer numbers. A finite monogenic semigroup $S = \langle a \rangle$ also has simple structure, see [21]. There are positive integer numbers $r$ and $m$ called the index and the period of $S$ such that

- $S = \{a, a^2, \ldots, a^{r+m-1}\}$ and $r + m - 1 = |S|$;
- $a^{r+m} = a^r$;
- $C_m := \{a^n, a^{n+1}, \ldots, a^{n+m-1}\}$ is a cyclic and maximal subgroup of $S$ with the neutral element $e = a^n \in C_m$ and generator $a^{n+1}$, where $n \in (m \cdot \mathbb{N}) \cap \{r, \ldots, r + m - 1\}$.
From now on, we denote by $M_{r,m}$ a finite monogenic semigroup of index $r$ and period $m$. Consider the shift

$$\sigma : M_{r,m} \to aM_{r,m}, \quad \sigma : x \mapsto ax,$$

and observe that for every $k \in \mathbb{N}$ the shift $\sigma^k : M_{r,m} \to a^kM_{r,m}, \sigma^k : x \mapsto a^kx$, coincides with the $k$th iteration of $\sigma$.

Observe also that the subset $a^kM_{r,m} = \sigma^k(M_{r,m})$ coincides with the characteristic ideal $M_{r,m}^{(k+1)}$ of $M_{r,m}$. For $k \geq r$ the characteristic ideal $M_{r,m}^{k} = a^{k-1}M_{r,m}$ coincides with the minimal ideal of $M_{r,m}$ and with a maximal subgroup $C_m$ of $M_{r,m}$. For the idempotent $e = a^n$ of the group $C_m$ the shift $\sigma^n : M_{r,m} \to a^nM_{r,m} = C_m$ is a homomorphic retraction of $M_{r,m}$ onto its maximal subgroup $C_m$. This retraction will be denoted by $\rho$.

The following lemma distinguishes some characteristic ideals in the semigroup $\lambda(M_{r,m})$.

**Lemma 3.1.** For every $k \geq 2$ the subsemigroup $\lambda(M_{r,m})$ of $\lambda(M_{r,m})$ coincides with the characteristic ideal of $\lambda(M_{r,m})^k$ of the semigroup $\lambda(M_{r,m})$.

**Proof.** By the functoriality of the superextension, the surjective map

$$\sigma^{k-1} : M_{r,m} \to a^{k-1}M_{r,m} = a^kM_{r,m}, \quad \sigma^{k-1} : x \mapsto a^{k-1}x,$$

induces the surjective map $\lambda\sigma^{k-1} : \lambda(M_{r,m}) \to \lambda(M_{r,m}^k), \lambda\sigma^{k-1} : A \mapsto a^{k-1} * A$. Then for every maximal linked upfamily $B \in \lambda(a^{k-1}M_{r,m})$ we can find a maximal linked upfamily $A \in \lambda(M_{k,m})$ with $B = a^{k-1} * A$ and conclude that $B = a^{k-1} + A \in \lambda(M_{k,m})^k$.

On the other hand, the definition of the semigroup operation on $\lambda(M_{r,m})$ implies that $\lambda(M_{r,m})^k \subset \lambda(M_{r,m}) = \lambda(a^{k-1}M_{r,m})$. So, $\lambda(M_{r,m}) = \lambda(M_{r,m})^k$ is a characteristic ideal in $\lambda(M_{r,m})$.

**Theorem 3.2.** Two finite monogenic semigroups are isomorphic if and only if their superextensions are isomorphic.

**Proof.** If two semigroups are isomorphic, then their superextensions are isomorphic by the functoriality of the superextension in the category of semigroups [15]. Now assume that two monogenic semigroups $M_{i,m}$ and $M_{j,n}$ have isomorphic superextensions. Let $\psi : \lambda(M_{i,m}) \to \lambda(M_{j,n})$ be an isomorphism.

Let $C_m$ be the maximal subgroup of $M_{i,m}$. By Lemma 3.1, the superextension $\lambda(C_m)$ is a characteristic sub-semigroup of $\lambda(M_{i,m})$, equal to the intersection $\bigcap_{k \in \mathbb{N}} \lambda(M_{i,m})^k$ of the characteristic ideals $\lambda(M_{i,m})^k$. Then

$$\psi(\lambda(C_m)) = \psi\left(\bigcap_{k \in \mathbb{N}} \lambda(M_{i,m})^k\right) = \bigcap_{k \in \mathbb{N}} \psi(\lambda(M_{i,m})^k) = \bigcap_{k \in \mathbb{N}} \left(\psi(\lambda(M_{i,m}))\right)^k = \bigcap_{k \in \mathbb{N}} \lambda(M_{j,n})^k = \lambda(C_n)$$

and hence $|\lambda(C_m)| = |\lambda(C_n)|$.

Observe that two finite sets $X,Y$ have the same cardinality if $|\lambda(X)| = |\lambda(Y)|$. Indeed, assuming that $|X| < |Y|$ we can choose an injective map $f : X \to Y$ with $f(X) \neq Y$ and obtain an injective map $f' : \lambda(\lambda(X)) \to \lambda(Y)$ with $\lambda f' = \lambda f$, which implies that $|\lambda(X)| < |\lambda(Y)|$. Now we see that the equality $|\lambda(C_m)| = |\lambda(C_n)|$ implies $n = m$.

On the other hand, the equality $|\lambda(M_{i,m})| = |\lambda(M_{j,n})|$ implies $i + m - 1 = |M_{i,m}| = |M_{j,n}| = j + n - 1$. Since $m = n$, we obtain that $i = j$ and hence $M_{i,n} = M_{j,m}$.

**Proposition 3.3.** If $r \geq 3$, then any automorphism $\psi$ of the semigroup $\lambda(M_{r,m})$ has $\psi(x) = x$ for all $x \in M_{r,m}$.

**Proof.** Let $a$ be the (unique) generator of the monogenic semigroup $M_{r,m}$. By Lemma 3.1, $a \ast \lambda(M_{r,m}) = \lambda(M_{r,m})^2$ is a characteristic ideal in $\lambda(M_{r,m})$. Then for any automorphism $\psi \in \operatorname{Aut}(\lambda(M_{r,m}))$ we get

$$\psi(a) \ast \lambda(M_{r,m}) = \psi(a) \ast \psi(\lambda(M_{r,m})) = \psi(a \ast \lambda(M_{r,m})) = a \ast \lambda(M_{r,m}) = a^2$$

and hence $a^2 = \psi(a) \ast A$ for some $A \in \lambda(M_{r,m})$. Taking into account that for $r \geq 3$, the equality $a^2 = x \ast y$ has a unique solution $x = y = a$ in $\lambda(M_{r,m})$, we conclude that $\psi(a) = a$ and hence $\psi(x) = x$ for all $x \in M_{r,m}$.

In the following proposition by $e$ we denote the unique idempotent of the group $C_m \subset M_{r,m}$ and by $\rho : M_{r,m} \to C_m, \rho : x \mapsto ex$, the homomorphic retraction of $M_{r,m}$ onto $C_m$. The homomorphic retraction $\rho$ induces a homomorphic retraction $\bar{\rho} : \lambda(M_{r,m}) \to \lambda(C_m), \bar{\rho} : A \mapsto e * A$.

**Theorem 3.4.** For $r = 2$ the homomorphic retraction $\bar{\rho} : \lambda(M_{r,m}) \to \lambda(C_m) \subset \lambda(M_{r,m})$ has the following properties:

1. $A * B = \bar{\rho}(A) * B = A * \bar{\rho}(B) = \bar{\rho}(A) * \bar{\rho}(B)$ for any $A,B \in \lambda(M_{r,m})$;
2. $\psi(x) = x$ for any $x \in C_m$ and any $\psi \in \operatorname{Aut}(\lambda(M_{r,m}))$;
(3) the homomorphic retraction $\tilde{\rho}$ is an auto-good shift of $\lambda(M_{r,m})$;
(4) the operator $R : \text{Aut}(\lambda(M_{r,m})) \to \text{Aut}(\lambda(C_m))$ has kernel isomorphic to $\prod_{\ell \in M(C_m)} S_{\rho^{-1}(\ell)} \setminus \{\ell\}$ and the range $R(\text{Aut}(M_{r,m})) = \{\varphi \in \text{Aut}(\lambda(C_m)) : \forall \lambda \in \lambda(C_m) \mid |\tilde{\rho}^{-1}(\varphi(\lambda))| = |\tilde{\rho}^{-1}(\lambda)|\}$.

Proof. 1. The first statement follows from the definition of the semigroup operation on $\lambda(M_{r,m})$ and the equality $xy = \rho(x) \cdot y = x \cdot \rho(y) = \rho(x \cdot y)$ holding for any elements $x, y \in M_{r,m} = M_{2,m}$.

2. Fix any automorphism $\psi$ of the semigroup $\lambda(M_{r,m})$. By Lemma 3.1, $\lambda(C_m)$ is a characteristic ideal of $\lambda(M_{r,m})$, so the restriction $\psi|\lambda(C_m)$ is an automorphism of the semigroup $\lambda(C_m)$. In [9] it was proved that $\psi(C_m) = C_m$. Taking into account that $e$ is a unique idempotent of $C_m$, we conclude that $\psi(e) = e$.

Since $\psi$ is an automorphism of $\lambda(M_{r,m})$, for every $A \in \lambda(M_{r,m})$ we have

$$\psi(\tilde{\rho}(A)) = \psi(e \ast A) = \psi(e) \ast \psi(A) = e \ast \psi(A) = \tilde{\rho}(\psi(A)),$$

which implies that $\psi(\tilde{\rho}^{-1}(B)) = \tilde{\rho}^{-1}(\psi(B))$ and hence $|\tilde{\rho}^{-1}(B)| = |\tilde{\rho}^{-1}(\psi(B))|$ for all $B \in \lambda(C_m)$. In particular, for the generator $a$ of the semigroup $M_{r,m}$ we get $|\tilde{\rho}^{-1}(ae)| = |\tilde{\rho}^{-1}(\psi(\lambda_{ae}))|$. Now observe that $\tilde{\rho}^{-1}(ae) = \tilde{\rho}^{-1}(\psi(\lambda_{ae})) = \{ae, a\}$ and $\tilde{\rho}^{-1}(x) = \tilde{\rho}^{-1}(x) = \{x\}$ for any $x \in C_m \setminus \{ae\}$. This implies that $\psi(\lambda_{ae}) = ae$ and hence $\psi(x) = x$ for all $x \in C_m$ (as $ae$ is a generator of the group $C_m$).

3. The third statement follows from the preceding two statements.

4. The fourth statement follows from the preceding statement and Theorem 2.3. $\square$

Lemma 3.5. If $r \geq 2$, then the map

$$\tilde{\sigma} : \lambda(M_{r,m}) \to \lambda(M_{r,m}^2), \quad \tilde{\sigma} : A \mapsto a \ast A$$

is an auto-shift of the semigroup $\lambda(M_{r,m})$.

Proof. It is clear that $\tilde{\sigma}(\lambda(M_{r,m})) = a \ast \lambda(M_{r,m}) = \lambda(M_{r,m})^2$. Next, we show that $\tilde{\sigma} \circ \psi = \psi \circ \tilde{\sigma}$ for every automorphism $\psi$ of $\lambda(M_{r,m})$.

If $r \geq 3$, then $\psi(a) = a$ by Proposition 3.3 and hence

$$\psi \circ \tilde{\sigma}(A) = \psi(a \ast A) = \psi(a) \ast \psi(A) = a \ast \psi(A) = \tilde{\sigma} \circ \psi(A)$$

for any $A \in \lambda(M_{r,m})$.

If $r = 2$, then $ax = aex$ for any $x \in M_{r,m}$. By Theorem 3.4, $\psi(\lambda_{ae}) = ae$ and then

$$\psi \circ \tilde{\sigma}(A) = \psi(a \ast A) = \psi(\lambda_{ae} \ast A) = \psi(\lambda_{ae}) \ast \psi(A) = ae \ast \psi(A) = a \ast \psi(A) = \tilde{\sigma} \circ \psi(A)$$

for any $A \in \lambda(M_{r,m})$.

It remains to prove that for any $A, A' \in \lambda(M_{r,m})$ with $\tilde{\sigma}(A) = \tilde{\sigma}(A')$ the equalities $A \ast B = A' \ast B$ and $B \ast A = B \ast A'$ hold for all $B \in \lambda(M_{r,m})$.

It follows from $a \ast A = \tilde{\sigma}(A) = \tilde{\sigma}(A') = a \ast A'$ that $a^n \ast A = a^n \ast A'$ for all $n \in \mathbb{N}$ and hence $x \ast A = x \ast A'$ for all $x \in M_{r,m}$. To see that $B \ast A = B \ast A'$, take any set $C \in B \ast A$ and find a set $B \in B$ and a family $(A_b)_{b \in B} \in A^B$ such that $\bigcup_{b \in B} a_b \subset C$. For every $b \in B$, we can use the equality $b_a \subset b \ast A = b \ast A'$ to find a set $A'_b \in A'$ such that $b'_a \subset b'_a$. Then

$$B \ast A' = \bigcup_{b \in B} b'_a \subset \bigcup_{b \in B} b_a \subset C$$

and hence $C \in B \ast A'$. By analogy we can prove that $B \ast A' \subset B \ast A$.

Next, we prove that $A \ast B = A' \ast B$. Given any element $C \in A \ast B$, find a set $A \in A$ and a family $(B_x)_{x \in A} \subset B$ such that $\bigcup_{x \in A} x B_x \subset C$. Since $aA \in A \ast A = a \ast A'$, there exists a set $A' \in A'$ such that $aB_x \subset aA$. For any $y \in A'$ find $x \in A$ with $ay = ax$ and put $B_x := B_x$. We claim that $\bigcup_{y \in A'} y B_y \subset C$. Indeed, for any $z \in \bigcup_{y \in A'} y B_y$ we can find $y \in A'$ and $b \in B_y$ such that $z = y b \in y B_y$. For the element $y$ there exists an element $x \in A$ such that $ax = ay$ and $B_x = B_y$. The equality $ax = ay$ implies $a^k x = a^k y$ for all $k \in \mathbb{N}$. In particular, $bx = by$. Then $z = y b = by = bx \in x B_x \subset C$ and hence $A' \ast B = \bigcup_{y \in A'} y B_y \subset C$, which implies $C \in A' \ast B$ and $A \ast B \subset A' \ast B$.

By analogy we can prove that $A' \ast B \subset A \ast B$ and thus $A' \ast B = A \ast B$. $\square$

Corollary 3.6. If $r \geq 2$, then for any $k \in \mathbb{N}$ the map

$$\tilde{\sigma}_k : \lambda(M_{r,m})^k \to \lambda(M_{r,m}^{k+1}), \quad \tilde{\sigma}_k : A \mapsto a \ast A,$$

is a good shift of the semigroup $\lambda(M_{r,m})$.

Lemma 3.5 and Theorem 2.3 have the following:
Corollary 3.7. Assume that \( r \geq 2 \). The operator \( R : \text{Aut}(\lambda(M_{r,m})) \to \text{Aut}(\lambda(M_{r,m}^2)) \) has kernel isomorphic to \( \prod_{\mathcal{L} \in \lambda(M_{r,m}^2)} S_{\delta^{-1}(\mathcal{L})} \cap \lambda(M_{r,m}^2) \) and range \( \text{Range}(\text{Aut}(M_{r,m}^2)) \subset H \) where
\[
H = \{ \varphi \in \text{Aut}(\lambda(M_{r,m}^2)) : \forall \mathcal{L} \in \lambda(M_{r,m}^2) \varphi(\delta^{-1}(\mathcal{L}) \cap \lambda(M_{r,m}^2)) = \delta^{-1}(\mathcal{L}) \cap \lambda(M_{r,m}^2) \text{ and } \\
\forall C \in \mathcal{C}_{\lambda(M_{r,m})} |\delta^{-1}(\varphi(C)) \cap C| = |\delta^{-1}(C) \cap C| \}.
\]

4. Automorphism groups of superextensions of monogenic semigroups of cardinality \( \leq 5 \)

In this section we shall describe the structure of the automorphism groups of superextensions of all monogenic semigroups \( M_{r,m} \) of cardinality \( |M_{r,m}| \leq 5 \).

4.1. The semigroups \( \lambda(M_{1,1}), \lambda(M_{1,2}) \) and \( \lambda(M_{2,1}) \). For any \( r, m \in \N \) with \( r + m \leq 3 \), the monogenic semigroup \( M_{r,m} \) has cardinality \( |M_{r,m}| \leq 2 \). Consequently, \( \lambda(M_{r,m}) = M_{r,m} \) and \( \text{Aut}(\lambda(M_{r,m})) = \text{Aut}(M_{r,m}) \cong C_1 \).

4.2. The semigroups \( \lambda(M_{1,3}), \lambda(M_{2,2}) \) and \( \lambda(M_{3,1}) \). For a monogenic semigroup \( M_{r,m} \) with \( r + m = 4 \) and generator \( \alpha \), the superextension \( \lambda(M_{r,m}) \) consists of three principal ultrafilters \( a, a^2, a^3 \) and the maximal linked family \( \Delta = \{ \{a, a^2\}, \{a, a^3\}, \{a^2, a^3\} \} \).

Taking into account that \( M_{1,3} \) is isomorphic to \( C_3 \) and \( \lambda(C_3) \cong C_2 \) (see Table 1), we conclude that \( \text{Aut}(\lambda(M_{1,3})) \cong \text{Aut}(\lambda(C_3)) \cong C_2 \).

By Proposition 3.3, for any \( i \in \{1, 2, 3\} \) and \( \psi \in \text{Aut}(\lambda(M_{3,1})) \) we have \( \psi(a^i) = a^i \). Then \( \psi(\Delta) = \Delta \) and hence \( \text{Aut}(\lambda(M_{3,1})) \cong C_1 \).

To recognize the automorphism group of \( \lambda(M_{2,2}) \), consider the homomorphic retraction \( \hat{\rho} : \lambda(M_{2,2}) \to \lambda(M_{2,2}^2) = \{a^2, a^3\} \), \( \hat{\rho} : A \mapsto a^2 \cdot A \)
and observe that it has fibers: \( \hat{\rho}^{-1}(a^2) = \{a^2\} \) and \( \hat{\rho}^{-1}(a^3) = \{a, a^3, \Delta\} \). Since the automorphism group \( \text{Aut}(\lambda(M_{2,2})) \cong \text{Aut}(\lambda(C_2)) \) is trivial, we can apply Theorem 3.4 and conclude that the automorphism group \( \text{Aut}(\lambda(M_{2,2})) \) is isomorphic to \( S_{\hat{\rho}^{-1}(a^3) \setminus \{a^3\}} = S_{\{a, \Delta\}} \cong C_2 \).

4.3. The semigroup \( \lambda(M_{1,4}) \). The semigroup \( M_{1,4} \) is isomorphic to the cyclic group \( C_4 \). Therefore,
\[
\text{Aut}(\lambda(M_{1,4})) \cong \text{Aut}(\lambda(C_4)) \cong C_2 \times C_2,
\]
according to [9] (see also Table 1).

4.4. The semigroup \( \lambda(M_{2,3}) \). Consider the monogenic semigroup \( M_{2,3} = \{a, a^2, a^3, a^4 \mid a^5 = a^2\} \) generated by the element \( \alpha \). Its superextension \( \lambda(M_{2,3}) \) contains 12 elements of the form:
\[
a^i, \quad \Delta_i = \langle A : A \subset M_{2,3} \setminus \{a^i\}, |A| = 2 \rangle, \quad \text{and} \quad \Box_i = \langle M_{2,3} \setminus \{a^i\}, \{a^i, x : x \in M_{2,3} \setminus \{a^i\}\} \rangle
\]
where \( i \in \{1, 2, 3, 4\} \).

Let \( \varepsilon = a^3 \) be the idempotent of the subgroup \( C_3 \) and \( \rho : M_{2,3} \to C_3, \rho : x \mapsto \varepsilon x, \) be the homomorphic retraction of \( M_{2,3} \) onto \( C_3 \). The map \( \rho \) induces a homomorphic retraction \( \hat{\rho} : \lambda(M_{2,3}) \to \lambda(C_3) = \{a^2, a^3, a^4, \Delta_1\} \), defined by \( \hat{\rho}(A) = a^3 \cdot A \) for \( A \in \lambda(M_{2,3}) \). By routine calculations we can show that the map \( \hat{\rho} \) has fibers:
- \( \hat{\rho}^{-1}(a^2) = \{a^2\} \);
- \( \hat{\rho}^{-1}(a^3) = \{a^3\} \);
- \( \hat{\rho}^{-1}(a^4) = \{a, a^4, \Delta_2, \Delta_3, \Box_1, \Box_4\} \);
- \( \hat{\rho}^{-1}(\Delta_1) = \{\Delta_1, \Delta_4, \Box_2, \Box_4\} \).

Applying Theorem 3.4, we can show that the automorphism group \( \text{Aut}(\lambda(M_{2,3})) \) of \( \lambda(M_{2,3}) \) is isomorphic to
\[
S_{\hat{\rho}^{-1}(\Delta_1) \setminus \{\Delta_1\}} \times S_{\hat{\rho}^{-1}(a^4) \setminus \{a^4\}} \cong S_3 \times S_5.
\]

4.5. The semigroup \( \lambda(M_{3,2}) \). In this section we consider the monogenic semigroup \( M_{3,2} = \{a, a^2, a^3, a^4\} \) generated by an element \( a \) such that \( a^5 = a^3 \). The semigroup \( M_{3,2} \) contains the characteristic ideals \( M_{3,2}^2 = \{a^2, a^3, a^4\} \) and \( M_{3,2}^3 = \{a^2, a^3, a^4\} = C_2 \).

Using the notations from the preceding subsection, we can see that the superextensions of the semigroups \( M_{3,2}^k \) contain the following elements:
- \( \lambda(M_{3,2}) = \{a^i, \Delta_i, \Box_i : 1 \leq i \leq 4\} \);
- \( \lambda(M_{3,2}^2) = \{a^2, a^3, a^4, \Delta_1\} \);
- \( \lambda(M_{3,2}^3) = \lambda(C_2) = C_2 = \{a^3, a^4\} \).
By Lemma 3.5, the map \( \sigma : \lambda(M_{3,2}) \to \lambda(M_{3,2}^2) \), \( \sigma : A \mapsto a \ast A \), is an auto-shift of the semigroup \( \lambda(M_{3,2}) \).

By the routine calculations it can be shown that the map \( \sigma \) has the following fibers:

- \( \sigma^{-1}(a^2) = \{a\} \);
- \( \sigma^{-1}(a^3) = \{a^2, a^4, \triangle_1, \triangle_3, \square_2, \square_4\} \);
- \( \sigma^{-1}(a^4) = \{a^3\} \);
- \( \sigma^{-1}(\triangle_1) = \{\triangle_2, \triangle_4, \square_1, \square_3\} \).

By Corollary 3.6, the restriction \( \sigma_2 = \sigma|\lambda(M_{3,2}^2) \) is a good shift of the semigroup \( \lambda(M_{3,2}^2) \). This shift has a unique fiber \( \sigma_2^{-1}(a^3) = \{a^2, a^4, \triangle_1\} \) containing more than one point. By Proposition 2.2, the automorphism group \( \text{Aut} \left( \lambda(M_{3,2}^2) \right) \) contains the permutation group \( S_{\{a^2, \triangle_1\}} \cong C_2 \). Taking into account that \( C_2 \) is a characteristic subgroup of \( \lambda(M_{3,2}^2) \) with trivial automorphism group, we conclude that \( \text{Aut} \left( \lambda(M_{3,2}^2) \right) = S_{\{a^2, \triangle_1\}} \cong C_2 \).

By Corollary 3.7, the restriction operator \( R : \text{Aut} \left( \lambda(M_{3,2}) \right) \to \text{Aut} \left( \lambda(M_{3,2}^2) \right) \cong C_2 \) has kernel isomorphic to \( S_{\sigma^{-1}(a^2) \setminus \lambda(M_{3,2}^2)} \times S_{\sigma^{-1}(\triangle_1) \setminus \lambda(M_{3,2}^2)} \cong S_3 \times S_4 \).

We claim that the subgroup \( R(\text{Aut} \left( \lambda(M_{3,2}) \right)) \) of \( \text{Aut} \left( \lambda(M_{3,2}^2) \right) = S_{\{a^2, \triangle_1\}} \) is trivial. Indeed, each automorphism \( \phi \in R(\text{Aut} \left( \lambda(M_{3,2}) \right)) \) is trivial on the subgroup \( C_2 = \{a^3, a^4\} \), so \( \phi(a^2) \in \{a^2, \triangle_1\} \). By Corollary 3.7,

\[
1 = |\sigma^{-1}(a^2)| = |\sigma^{-1}(\phi(a^2))| < 4 = |\sigma^{-1}(\triangle_1)|,
\]

which implies that \( \phi(a^2) = a^2 \) and \( \phi \) is the identity automorphism of \( \text{Aut} \left( \lambda(M_{3,2}^2) \right) \). Consequently, the range of the restriction operator \( R \) is trivial and the group \( \text{Aut} \left( \lambda(M_{3,2}) \right) \) coincides with the kernel of \( R \) and hence is isomorphic to \( S_3 \times S_4 \).

4.6. The semigroup \( \lambda(M_{4,1}) \). In this subsection we consider the monogenic semigroup \( M_{4,1} = \{a, a^2, a^3, a^4\} \) generated by an element \( a \) such that \( a^5 = a^4 \). The semigroup \( M_{4,1} \) contains the characteristic ideals \( M_{4,1}^2 = \{a^2, a^3, a^4\} \), \( M_{4,1}^3 = \{a^3, a^4\} \), and \( M_{4,1}^4 = \{a^4\} \).

Using the notations from the preceding subsection, we can see that the superextensions of the semigroups \( M_{4,1}^k \) contain the following elements:

- \( \lambda(M_{4,1}) = \{a^i, \triangle_1, \square_i : 1 \leq i \leq 4\} \);
- \( \lambda(M_{4,1}^2) = \{a^2, a^4, \triangle_1\}; \)
- \( \lambda(M_{4,1}^3) = \{a^3, a^4\}; \)
- \( \lambda(M_{4,1}^4) = \{a^4\}. \)

It is clear that the semigroups \( \lambda(M_{4,1}^k) \) and \( \lambda(M_{4,1}^k) \) have trivial automorphism groups.

Taking into account that \( xy = a^k \) for any \( x, y \in \lambda(M_{4,1}^k) = \{a^2, a^3, a^4, \triangle_1\} \), we conclude that the automorphism group \( \text{Aut} \left( \lambda(M_{4,1}^k) \right) \) of the semigroup \( M_{4,1}^k \) is isomorphic to the symmetric group \( S_3 \).

By Lemma 3.5, the map \( \sigma : \lambda(M_{4,1}) \to \lambda(M_{4,1}^2) \), \( \sigma : A \mapsto a \ast A \), is an auto-shift of the semigroup \( \lambda(M_{4,1}) \). By the routine calculations it can be shown that the map \( \sigma \) has the following fibers:

- \( \sigma^{-1}(a^2) = \{a\} \);
- \( \sigma^{-1}(a^3) = \{a^2\} \);
- \( \sigma^{-1}(a^4) = \{a^3, a^4, \triangle_1, \triangle_2, \square_3, \square_4\} \);
- \( \sigma^{-1}(\triangle_1) = \{\triangle_3, \triangle_4, \square_1, \square_2\} \).

By Corollary 3.7, the restriction operator \( R : \text{Aut} \left( \lambda(M_{4,1}) \right) \to \text{Aut} \left( \lambda(M_{4,1}^2) \right) \) has kernel isomorphic to \( S_{\sigma^{-1}(a^2) \setminus \lambda(M_{4,1}^2)} \times S_{\sigma^{-1}(\triangle_1) \setminus \lambda(M_{4,1}^2)} = S_{\{a^2, \triangle_1\}} \times S_{\{\triangle_3, \triangle_4, \square_1, \square_2\}} \cong S_3 \times S_4 \).

By Proposition 3.3, for any automorphism \( \psi \) of \( \lambda(M_{4,1}) \), we get \( \psi(a^k) = a^k \) for any \( k \in \mathbb{N} \). Taking into account that \( \lambda(M_{4,1}^2) = \{a^2, a^3, a^4, \triangle_1\} \) is a characteristic ideal in \( \lambda(M_{4,1}) \), we conclude that \( \psi(\triangle_1) = \triangle_1 \). Consequently, the range of the restriction operator \( R \) is trivial and the group \( \text{Aut} \left( \lambda(M_{4,1}) \right) \) coincides with the kernel of \( R \) and hence is isomorphic to \( S_3 \times S_4 \).

4.7. The semigroup \( \lambda(M_{1,5}) \). The monogenic semigroup \( M_{1,5} \) is isomorphic to the cyclic group \( C_5 \). It was proved in [9] that the automorphism group \( \text{Aut} \left( \lambda(M_{1,5}) \right) \cong \text{Aut} \left( \lambda(C_5) \right) \) is isomorphic to \( C_4 \).
4.8. The semigroup \( \lambda(M_{2,4}) \). To describe the structure of the automorphism group \( \text{Aut}(\lambda(M_{2,4})) \), we shall apply Theorem 3.4.

Consider the homomorphic retraction

\[
\bar{\rho} : \lambda(M_{2,4}) \to \lambda(M_{2,4}^2), \quad \bar{\rho} : \mathcal{L} \mapsto e \star \mathcal{L},
\]

where \( e = a^4 \in C_4 \subset M_{2,4} \) is the unique idempotent of the semigroup \( M_{2,4} \).

To describe the fibers of the retraction \( \bar{\rho} \) we first introduce a convenient notation for all 81 elements of the superextension \( \lambda(M_{2,4}) \). We recall that \( M_{2,4} = \{a, a^2, a^3, a^4, a^5\} \) and \( C_4 = \{a^2, a^3, a^4, a^5\} \) where \( a^6 = a^2 \).

The 81 elements of the semigroup \( \lambda(M_{2,4}) \) will be denoted as follows:

- \( a^j \) for \( j \in \{1, 2, 3, 4, 5\} \);
- \( \bigcirc := \{A \subset M_{2,4} : |A| \geq 3\} \);
- \( \Theta_{ij} := \{\{a^i, a^j\}, A : A \subset M_{2,4}, |A| = 3, |A \cap \{a^i, a^j\}| = 1\} \) for \( 1 \leq i < j \leq 5 \);
- \( \Delta_{ijk} := \{\{a^i, a^j, a^k\}, \{a^j, a^k\}\} \) for numbers \( 1 \leq i < j < k \leq 5 \);
- \( \lambda' := \{a, \lambda, a, \lambda \} \); for \( i, j, k \);
- \( \lambda'_{ijk} := \{\{a^i, a^j, a^k\}, \{a^i, a^j, a^k\}\} \) for numbers \( 1 \leq i < j < k \leq 5 \) and \( n \in \{1, 2, 3, 4, 5\} \) \( \setminus \{i, j, k\} \);
- \( \lambda'_{ijk} := \{\{a^i, a^j, a^k\}, a, \lambda, a, \lambda\} \) for \( 1 \leq j < k \leq 5 \) and \( i \in \{1, 2, 3, 4, 5\} \) \( \setminus \{j, k\} \).

Observe that for the subgroup \( C_4 = \{a^2, a^3, a^4, a^5\} \subset M_{2,4} \) we have

\[
\lambda(C_4) = C_4 \cup \{\Delta_{2345}, \Delta_{2354}, \Delta_{2453}, \Delta_{3452}, \Delta_{3425}, \Delta_{3524}, \Delta_{5234}, \Delta_{5243}\}.
\]

By routine calculations it can be shown that the map \( \bar{\rho} : \lambda(M_{2,4}) \to \lambda(C_4) \) has the following fibers:

- \( \bar{\rho}^{-1}(\{x\}) = \{x\} \) for \( x \in \{a^2, a^3, a^4, a^5\} \);
- \( \bar{\rho}^{-1}(\lambda') = \{\lambda, a, \lambda, a, \lambda\} \) for \( \Delta_{2345} \);
- \( \bar{\rho}^{-1}(\{\lambda\}) = \{\lambda, a, \lambda, a, \lambda\} \) for \( \Delta_{2354} \);
- \( \bar{\rho}^{-1}(\{\lambda\}) = \{\lambda, a, \lambda, a, \lambda\} \) for \( \Delta_{2453} \);
- \( \bar{\rho}^{-1}(\{\lambda\}) = \{\lambda, a, \lambda, a, \lambda\} \) for \( \Delta_{3452} \);
- \( \bar{\rho}^{-1}(\{\lambda\}) = \{\lambda, a, \lambda, a, \lambda\} \) for \( \Delta_{3425} \);
- \( \bar{\rho}^{-1}(\{\lambda\}) = \{\lambda, a, \lambda, a, \lambda\} \) for \( \Delta_{3524} \);
- \( \bar{\rho}^{-1}(\{\lambda\}) = \{\lambda, a, \lambda, a, \lambda\} \) for \( \Delta_{5234} \);
- \( \bar{\rho}^{-1}(\{\lambda\}) = \{\lambda, a, \lambda, a, \lambda\} \) for \( \Delta_{5243} \).

By Theorem 3.4, for any automorphism \( \psi \) of \( \lambda(M_{2,4}) \) the restriction \( \psi|\lambda(C_4) \) is an automorphism of \( \lambda(C_4) \) such that \( \psi(x) = x \) for all \( x \in C_4 \). The description of the automorphism group of \( \lambda(C_4) \) given in [9] ensures that \( \psi(\Delta_{ij}) = \Delta_{ij} \) for any \( \Delta_{ij} \in \lambda(C_4) \).

By Theorem 3.4, the automorphism group \( \text{Aut}(\lambda(M_{2,4})) \) is isomorphic to

\[
\prod_{\mathcal{L} \in \mathcal{L}(C_4)} S_{\mathcal{L}}^{-1}(\mathcal{L}) \setminus \{\mathcal{L}\} \cong S_3^3 \times S_3^3 \times S_3 \times S_3 \times S_3.
\]

4.9. The semigroup \( \lambda(M_{3,3}) \). In this section we recognize the automorphism group of the superextension of the semigroup \( M_{3,3} = \{a, a^2, a^3, a^4, a^5\} \). This semigroup is generated by an element \( a \) such that \( a^6 = a^3 \). Observe that the ideal \( M_{3,3}^2 = \{a^2, a^3, a^4, a^5\} \) is isomorphic to the monogenic semigroup \( M_{2,3} = \{b, b^2, b^3, b^4\} \) as for the element \( b = a^2 \) we get \( \{b, b^2, b^3, b^4\} = \{a^2, a^3, a^4, a^5\} \).

As shown in Subsection 4.4, the automorphism group \( \text{Aut}(\lambda(M_{2,3})) \) consists of all bijections \( \psi \) of \( \lambda(M_{2,3}) \) such that

- \( \psi(x) = x \) for any \( x \notin \{\Delta_4, \Delta_2, \Delta_3, \Delta_1, \Delta_4\} \);
- the sets \{\Delta_1, \Delta_2, \Delta_3, \Delta_4\} are \( \psi \)-invariant.

Taking into account the isomorphism \( \{b, b^2, b^3, b^4\} \to \{a^2, a^3, a^4, a^5\} \) between the semigroups \( M_{2,3} \) and \( M_{3,3}^2 \), we obtain the following fact.

**Claim 4.1.** The automorphism group of the semigroup \( \lambda(M_{3,3}) \) consists of bijections \( \psi \) of \( \lambda(M_{3,3}) \) such that
4.10. The semigroup $\lambda(M_{4,2})$. In this section we recognize the structure of the automorphism group of the superextension of the semigroup $M_{4,2}$ and its characteristic ideals $M_{4,2}^k$ for $k \in \{2, 3, 4\}$. The monogenic semigroup $M_{4,2} = \{a, a^2, a^3, a^4, a^5\}$ is generated by an element $a$ such that $a^6 = a^4$. The characteristic ideal $M_{4,2}^4 = \{a^4, a^5\}$ is a group with neutral element $a^4$.

Observe that $\lambda(M_{4,2}^4) = M_{4,2}^4 \cong C_2$ and hence $\text{Aut}(\lambda(M_{4,2}^4)) \cong \text{Aut}(C_2) \cong C_1$.

To recognize the structure of the automorphism groups of the superextensions of the semigroups $M_{4,2}^3 = \{a^3, a^4, a^5\}$ and $M_{4,2}^2 = \{a^2, a^3, a^4, a^5\}$, observe that the map $\rho : M_{4,2}^2 \to M_{4,2}^4$, $\rho : x \mapsto a^4x = a^2x$, is a homomorphic retraction of $M_{4,2}^4$ onto the group $M_{4,2}^2$ such that $xy = \rho(x) \cdot \rho(y)$ for all $x, y \in M_{4,2}^2$. This homomorphic
retraction induces a homomorphic retraction
\[ \hat{\rho} : \lambda(M_{4,2}^2) \to \lambda(M_{4,2}^4), \quad \hat{\rho} : A \mapsto a^4 * A, \]
such that \( A * B = \hat{\rho}(A) * \hat{\rho}(B) \) for any \( A, B \in \lambda(M_{4,2}^2) \).

Using the notations for the elements of the superextension \( \lambda(M_{4,2}) \) from Subsection 4.8, observe that
\[ \lambda(M_{4,2}^2) = \{a^2 : 2 \leq i \leq 5\} \cup \{\Delta_{ijk} : 2 \leq i < j < k \leq 5\} \cup \{\hat{\rho}_n^\sigma : 2 \leq i < j < k \leq 5, n \in \{2, 3, 4, 5\} \setminus \{i, j, k\}\}.

By routine calculations it can be shown that the map \( \rho : \lambda(M_{4,2}^2) \to \lambda(M_{4,2}^4) = \{a^4, a^5\} \) has the following fibers:
\[ \begin{align*}
\rho^{-1}(a^4) &= \{a^2, a^4, \Delta_{234}, \Delta_{245}, \hat{\rho}_2^3, \hat{\rho}_2^4, \hat{\rho}_2^5\}; \\
\rho^{-1}(a^5) &= \{a^3, a^5, \Delta_{235}, \Delta_{345}, \hat{\rho}_3^2, \hat{\rho}_3^3, \hat{\rho}_3^4\}.
\end{align*} \]

Now we see that \( \operatorname{Aut}(\lambda(M_{4,2}^2)) \) is isomorphic to
\[ \prod_{i \in \{4, 5\}} S_{\rho^{-1}(a^i) \cap \lambda(M_{4,2}^4) \setminus M_{4,2}^4} = S_{\{a^3, \Delta_{345}\}} \cong C_2 \]
and \( \operatorname{Aut}(\lambda(M_{4,2}^2)) \) is isomorphic to
\[ \prod_{i \in \{4, 5\}} S_{\rho^{-1}(a^i) \setminus M_{4,2}^4} \cong S_5 \times S_5. \]

To detect the algebraic structure of the automorphism group of \( \lambda(M_{4,2}) \), consider the map \( \sigma : M_{4,2} \to M_{4,2}^4, \sigma : x \mapsto ax \), which induces the map
\[ \bar{\sigma} : \lambda(M_{4,2}) \to \lambda(M_{4,2}^2), \quad \bar{\sigma} : A \mapsto a * A. \]

By Lemma 3.5, \( \bar{\sigma} \) is an auto-shift of \( \lambda(M_{4,2}) \).

By routine calculations we can show that the map \( \bar{\sigma} \) has the following fibers:
\[ \begin{align*}
\bar{\sigma}^{-1}(a^2) &= \{a\}, \quad \bar{\sigma}^{-1}(a^3) = \{a^2\}, \quad \bar{\sigma}^{-1}(a^4) = \{a^4\}; \\
\bar{\sigma}^{-1}(a^3) &= \{a^3, a^5, \Delta_{135}, \Delta_{235}, \Delta_{345}, A_{15}, A_{25}, A_{35}, A_{13}, A_{23}, A_{34}, \hat{\rho}_3^2, \hat{\rho}_3^3, \hat{\rho}_3^4, \hat{\rho}_2^3, \hat{\rho}_2^4, \hat{\rho}_2^5\}; \\
\bar{\sigma}^{-1}(\Delta_{235}) &= \{\Delta_{124}\}; \\
\bar{\sigma}^{-1}(\Delta_{234}) &= \{\Delta_{123}, \Delta_{132}, A_{123}, A_{23}, A_{2}, A_{3}, A_{1}, A_{0}\}; \\
\bar{\sigma}^{-1}(\Delta_{245}) &= \{\Delta_{134}, A_{134}, A_{13}, A_{1}, A_{0}\}; \\
\bar{\sigma}^{-1}(\Delta_{345}) &= \{\Delta_{234}, \Delta_{245}, A_{2}, A_{1}, A_{0}\}; \\
\bar{\sigma}^{-1}(\hat{\rho}_3^2) &= \{\hat{\rho}_3^3, \hat{\rho}_3^4, A_1, A_2\}; \\
\bar{\sigma}^{-1}(\hat{\rho}_3^3) &= \{\hat{\rho}_3^4, \hat{\rho}_2^3, A_1, A_2\}; \\
\bar{\sigma}^{-1}(\hat{\rho}_3^4) &= \{\hat{\rho}_2^3, \hat{\rho}_2^4, A_1, A_2\}; \\
\bar{\sigma}^{-1}(\hat{\rho}_2^3) &= \{A_{1}, A_{0}\}. \end{align*} \]

Now consider the restriction operator
\[ R : \operatorname{Aut}(\lambda(M_{4,2})) \to \operatorname{Aut}(\lambda(M_{4,2}^2)), \quad R : \psi \mapsto \psi \circ \lambda(M_{4,2}^2). \]

We claim that this operator has trivial range.

Fix any automorphism \( \psi \in \operatorname{Aut}(\lambda(M_{4,2})) \). Proposition 3.3 ensures that \( \psi(a^i) = a^i \) for all \( i \in \{1, 2, 3, 4, 5\} \).

The description of the automorphism group \( \operatorname{Aut}(\lambda(M_{4,2}^2)) \) ensures that the sets \( \{a^2, a^4, \Delta_{234}, \Delta_{245}, \hat{\rho}_2^3, \hat{\rho}_2^4, \hat{\rho}_2^5\} \) and \( \{a^3, a^5, \Delta_{235}, \Delta_{345}, \hat{\rho}_3^3, \hat{\rho}_3^4, \hat{\rho}_3^5\} \) are \( \psi \)-invariant. Then the sets \( F_1 = \{\Delta_{234}, \Delta_{245}, \hat{\rho}_2^3, \hat{\rho}_2^4, \hat{\rho}_2^5\} \) and \( F_4 = \{\Delta_{235}, \Delta_{345}, \hat{\rho}_3^3, \hat{\rho}_3^4, \hat{\rho}_3^5\} \) are \( \psi \)-invariant, too. Taking into account that the ideal \( \lambda(M_{4,2}^2) = \{a^3, a^4, \Delta_{234}, \Delta_{245}\} \) is characteristic, we conclude that \( \psi(\Delta_{345}) = \Delta_{345} \). Consequently, the set \( F_3 = \{\Delta_{235}, \hat{\rho}_3^3, \hat{\rho}_3^4, \hat{\rho}_3^5\} \) is \( \psi \)-invariant and \( \psi(A) = A \) for any \( A \in \lambda(M_{4,2}^2) \setminus (F_1 \cup F_4) \).

It follows from \( \psi \circ \bar{\sigma} = \bar{\sigma} \circ \psi \) that
\[ |\bar{\sigma}^{-1}(\psi^{-1}(A)) \setminus \lambda(M_{4,2}^2)| = |\bar{\sigma}^{-1}(A) \setminus \lambda(M_{4,2}^2)| \]
for any \( A \in \lambda(M_{4,2}^2) \). Observe that
\[ \begin{align*}
\bar{\sigma}^{-1}(x) \setminus \lambda(M_{4,2}^2) &= 0 \quad \text{for} \quad x \in \{a^2, a^3, a^5\}; \\
|\bar{\sigma}^{-1}(a^2) \setminus \lambda(M_{4,2}^2)| &= \{|\Delta_{135}, \Delta_{235}, \Delta_{345}, A_{15}, A_{25}, A_{34}, \hat{\rho}_3^3, \hat{\rho}_3^4, \hat{\rho}_3^5, \hat{\rho}_2^3, \hat{\rho}_2^4, \hat{\rho}_2^5\}| = 14; \\
|\bar{\sigma}^{-1}(\Delta_{235}) \setminus \lambda(M_{4,2}^2)| &= \{|\Delta_{124}\}| = 1; \\
|\bar{\sigma}^{-1}(\Delta_{234}) \setminus \lambda(M_{4,2}^2)| &= \{|\Delta_{123}, \Delta_{132}, A_{123}, A_{23}, A_{2}, A_{3}, A_{1}, A_{0}\}| = 9; \\
|\bar{\sigma}^{-1}(\Delta_{245}) \setminus \lambda(M_{4,2}^2)| &= \{|\Delta_{134}, \Delta_{145}, A_{14}, A_{25}, A_{13}, A_{15}, A_{34}, \hat{\rho}_3^4, \hat{\rho}_3^5, \hat{\rho}_2^3, \hat{\rho}_2^4, \hat{\rho}_2^5, \hat{\rho}_1^3, \hat{\rho}_1^4, \hat{\rho}_1^5, \hat{\rho}_0^3, \hat{\rho}_0^4, \hat{\rho}_0^5\}| = 9.
\end{align*} \]
4.11. The semigroup $\lambda(M_{5,1})$. In this section we recognize the structure of the automorphism group of the superextension of the semigroup $M_{5,1}$ and its characteristic ideals $M_{5,1}^k$ for $k \in \{2, 3, 4, 5\}$. The monogenic semigroup $M_{5,1} = \{a, a^2, a^3, a^4, a^5\}$ is generated by an element $a$ such that $a^6 = a^5$. Observe that for any $x, y \in \{a^3, a^4, a^5\} = M_{5,1}^3$ we get $xy = a^6$. This implies that for any $k \in \{3, 4, 5\}$ any bijection $\psi$ of $\lambda(M_{5,1}^k)$ with $\psi(a^5) = a^3$ is an automorphism of the semigroup $\lambda(M_{5,1}^k)$. This observation implies that $\text{Aut}(\lambda(M_{5,1}^5)) \cong \text{Aut}(\lambda(M_{5,1}^4)) \cong C_1$ and $\text{Aut}(\lambda(M_{5,1}^3)) \cong S_3$.

Next, consider the semigroup $M_{5,1}^2 = \{a^2, a^3, a^4, a^5\}$ and its superextension $\lambda(M_{5,1}^2)$. It follows from $M_{5,1}^2 \ast M_{5,1}^1 = M_{5,1}^3 = \{a^4, a^5\}$ that $\lambda(M_{5,1}^2) \ast \lambda(M_{5,1}^1) = \lambda(M_{5,1}^4) = M_{5,1}^3$. This implies that the ideal $M_{5,1}^2$ is characteristic in the semigroup $\lambda(M_{5,1}^2)$. Since the semigroup $M_{5,1}^2 = \{a^4, a^5\}$ has trivial automorphism group, $\psi(a^4) = a^4$ and $\psi(a^5) = a^5$ for any automorphism $\lambda(M_{5,1}^2)$.

It is easy to show that the equation $x \ast y = a^2$ has a unique solution $x = y = a^2$ in the semigroup $\lambda(M_{5,1}^2)$. Consequently, $\psi(a^2) = a^2$ for any automorphism $\psi$ of $\lambda(M_{5,1}^2)$ and $\mathcal{A} \ast \mathcal{B} = a^5$ for any maximal linked upfamilies $\mathcal{A}, \mathcal{B} \in \lambda(M_{5,1}^2)$ such that $(\mathcal{A}, \mathcal{B}) \neq (a^2, a^2)$. It follows that any bijection $\psi$ of $\lambda(M_{5,1}^2)$ such that $\psi(a^i) = a^i$ for $i \in \{2, 4, 5\}$ is an automorphism of the semigroup $\lambda(M_{5,1}^2)$. This implies that $\text{Aut}(M_{5,1}^2) \cong S_5$.

To recognize the automorphism group of $\lambda(M_{5,1})$, consider the map $\sigma : \lambda(M_{5,1}) \rightarrow \lambda(M_{5,1}^2)$, $\sigma : A \mapsto a \ast A$.

By Lemma 3.5, $\sigma$ is an auto-shift of $\lambda(M_{5,1})$ and its restriction $\sigma_2 := \sigma|\lambda(M_{5,1}^2)$ is a good shift of $\lambda(M_{5,1}^2)$.

By a routine calculation, it can be shown that the map $\sigma$ has the following fibers:

- $\sigma^{-1}(a^i) = \{a^{i-1}\}$ for $i \in \{2, 3, 4\}$;
- $\sigma^{-1}(a^5) = \{a^4, a^5, A^3, \hat{A}^2, \hat{A}^4, \hat{A}^5, \Theta_{13}, \Theta_{15}, \Theta_{23}, \Theta_{25}, \Theta_{34}, \Theta_{45}, O\};$
- $\sigma^{-1}(\Delta_{234}) = \{\Delta_{234}\}$;
- $\sigma^{-1}(\Delta_{235}) = \{\Theta_{12}, \hat{A}^2_{345}, \hat{A}^5_{123}, \hat{A}^4_{12}, \hat{A}^3_{12}, \hat{A}^1_{12}, \hat{A}^5_{245}, \hat{A}^4_{245}, \hat{A}^3_{245}, \hat{A}^1_{245}, \Delta_{234}, \Delta_{245}, \Delta_{145}, \Theta_{45}\};$
- $\sigma^{-1}(\Delta_{245}) = \{\Theta_{13}, \hat{A}^2_{345}, \hat{A}^5_{123}, \hat{A}^4_{12}, \hat{A}^3_{12}, \hat{A}^1_{12}, \hat{A}^5_{245}, \hat{A}^4_{245}, \hat{A}^3_{245}, \hat{A}^1_{245}, \Delta_{234}, \Delta_{245}\}.$
To recognize the algebraic structure of the automorphism group Aut(\(\lambda(M_{5,1})\)), consider the restriction operator 
\(R : \text{Aut}(\lambda(M_{5,1})) \to \text{Aut}(\lambda(M_{5,1}^2))\). By Corollary 3.7, the kernel of this operator is isomorphic to

\[
\prod_{\mathcal{L} \in \lambda(M_{5,1}^2)} S_{\sigma^{-1}(\mathcal{L}) \setminus \lambda(M_{5,1}^2)} \cong S_{14} \times S_5 \times S_3 \times S_2 \times S_18.
\]

We claim that the operator \(R\) has trivial range. Given any automorphism \(\psi\) of \(\lambda(M_{5,1})\), we should prove that \(\psi(\mathcal{A}) = \mathcal{A}\) for any \(\mathcal{A} \in \lambda(M_{5,1}^2)\). By Proposition 3.3, \(\psi(\mathcal{A}) = \mathcal{A}\) for all \(i \in \{1, 2, 3, 4, 5\}\). The equality \(\psi(\mathcal{A}) = \mathcal{A}\) implies that \(\bar{\sigma} \circ \psi = \psi \circ \bar{\sigma}\). Consequently, for every \(\mathcal{L} \in \lambda(M_{5,1}^2)\) we have \(\psi(\sigma^{-1}(\mathcal{L})) = \sigma^{-1}(\psi(\mathcal{L}))\). Since the ideals \(\lambda(M_{5,1}^2)\) are characteristic in \(\lambda(M_{5,1})\), Corollary 3.7 ensures that

\[
|\sigma^{-1}(\psi(\mathcal{L})) \cap \lambda(M_{5,1}^k)| = |\sigma^{-1}(\mathcal{L}) \cap \lambda(M_{5,1}^k)|
\]

for all \(\mathcal{L} \in \lambda(M_{5,1}^2)\) and all \(k \in \{1, 2, 3, 4, 5\}\).

Comparing the cardinalities of the sets \(\sigma^{-1}(\mathcal{L}) \cap \lambda(M_{5,1}^k)\) for various \(k \in \{1, 2, 3, 4, 5\}\) and \(\mathcal{L} \in \lambda(M_{5,1}^2)\), we see that \(\psi(F_2) = F_2\), \(\psi(F_3) = F_3\) and \(\psi(\mathcal{A}) = \mathcal{A}\) for all \(\mathcal{A} \in M_{5,1}^2 \setminus (F_2 \cup F_3)\), where \(F_2 = \{\Delta_{235}, \Delta_{245}\}\) and \(F_3 = \{\Delta_{345}, \Delta_{245}, \Delta_{235}\}\).

Let us check that \(\psi(\Delta_{235}) = \Delta_{235}\). To derive a contradiction, assume that \(\psi(\Delta_{235}) \neq \Delta_{235}\) and hence \(\psi(\Delta_{235}) = \Delta_{245}\). Consider the element \(\Delta_{124} \in \bar{\sigma}^{-1}(\Delta_{235}) \setminus \lambda(M_{5,1}^2)\) and observe that \(\psi(\Delta_{124}) \in \psi(\sigma^{-1}(\Delta_{235})) = \sigma^{-1}(\psi(\Delta_{124})) = \sigma^{-1}(\Delta_{135})\). Let \(\pi : \lambda(M_{5,1}) \to \lambda(M_{5,1})\) be a permutation such that \(\pi(\psi(\Delta_{124})) = \Delta_{135}\) and \(\pi(\mathcal{A}) = \mathcal{A}\) for all \(\mathcal{A} \in \lambda(M_{5,1}) \setminus \{\Delta_{135}, \Delta_{124}\}\). By Corollary 3.7, the permutation \(\pi\) belongs to the automorphism group \(\text{Aut}(\lambda(M_{5,1}))\). Replacing \(\psi\) by \(\pi \circ \psi\), we can assume that \(\psi(\Delta_{124}) = \Delta_{135}\).

Observe that

\[
a^5 = \Delta_{135} \ast \Delta_{123} = \psi(\Delta_{124} \ast \psi(\Delta_{123}) = \psi(\Delta_{124} \ast \Delta_{123}) = \psi(\Delta_{345}) \neq a^5.
\]

This contradiction shows that \(\psi(\Delta_{235}) = \Delta_{235}\) and hence \(\psi(\Delta_{245}) = \Delta_{245}\) (as \(\psi(F_2) = F_2\)).

Next, we show that \(\psi(\mathcal{A}) = \mathcal{A}\) for any \(\mathcal{A} \in F_3 = \{\Delta_{345}, \Delta_{245}, \Delta_{235}\}\). To simplify notations, put \(\hat{\Delta}^2 := \Delta_{345}, \hat{\Delta}^3 := \Delta_{245}, \hat{\Delta}^4 := \Delta_{235}\). To derive a contradiction, assume that \(\psi(\hat{\Delta}^i) = \hat{\Delta}^j\) for some \(2 \leq i < j \leq 4\). Consider the maximal linked upfamily \(\Lambda_i \in \sigma^{-1}(\hat{\Delta}^i)\) and observe that \(\psi(\Lambda_i) \in \psi(\sigma^{-1}(\hat{\Delta}^i)) = \sigma^{-1}(\psi(\hat{\Delta}^i)) = \sigma^{-1}(\hat{\Delta}^j)\). Since \(\Lambda_i \in \bar{\sigma}^{-1}(\hat{\Delta}^i)\), we can replace \(\psi\) by the composition with the permutation exchanging \(\psi(\Lambda_i)\) with \(\psi(\Lambda_j)\) and \(\psi(\Delta_{134})\) with \(\psi(\Delta_{134})\), and assume that \(\psi(\Lambda_i^{-1}) = \Lambda_i^{-1}\) and \(\psi(\Delta_{134}) = \Delta_{134}\).

Now observe that the elements \(\Lambda_i, \Lambda^2, \Lambda^3\) can be algebraically distinguished by the equalities:

\[
\begin{align*}
\Lambda^1 \ast \Delta_{123} &= \Delta_{345}, & \Lambda^1 \ast \Delta_{134} &= \Delta_{135} \\
\Lambda^2 \ast \Delta_{123} &= \Delta_{345}, & \Lambda^2 \ast \Delta_{134} &= a^5 \\
\Lambda^3 \ast \Delta_{123} &= a^5, & \Lambda^3 \ast \Delta_{134} &= a^5.
\end{align*}
\]

Two cases are possible. If \(i = 2\), then \(\psi(\Lambda^1) = \Lambda^j^{-1}\) and we obtain a contradiction:

\[
a^5 = \psi(a^5) = \Lambda^j^{-1} \ast \Delta_{134} = \psi(\Lambda^1 \ast \Delta_{134}) = \psi(\Lambda^1 \ast \Delta_{134}) = \psi(\Delta_{345}) \neq a^5.
\]

If \(i = 3\), then we obtain a contradiction considering

\[
a^5 = \psi(a^5) = \Lambda^j^{-1} \ast \Delta_{123} = \psi(\Lambda^2) \ast \psi(\Delta_{123}) = \psi(\Lambda^2 \ast \Delta_{123}) = \psi(\Delta_{345}) \neq a^5.
\]

In both cases we obtain a contradiction with the assumption that \(\psi(\mathcal{A}) \neq \mathcal{A}\) for some \(\mathcal{A} \in F_3\). This contradiction completes the proof of the triviality of the range of the operator \(R\). Then the group \(\text{Aut}(\lambda(M_{5,1}))\) is equal to the kernel of the operator \(R\) and hence is isomorphic to the group \(S_4^2 \times S_5 \times S_2^7 \times S_{14} \times S_{18}\).
5. Summary Table and some Conjectures

The obtained results on the automorphism groups of superextensions of monogenic semigroups of cardinality \( \leq 5 \) are summed up in the following table.

| \( S \) | \( |S| = \) | \( S \cong \) | \( \text{Aut}(S) \cong \) | \( \text{Aut}(\lambda(S)) \cong \) | \( |\text{Aut}(\lambda(S))| = \) |

| \( M_{5,1}^5 \) | 1 | \( C_1 \) | \( C_1 \) | \( 1 \) |

Analyzing the entries of this table and the arguments in Section 4, we can make the following conjectures.

Conjecture 5.1. For any integer numbers \( r, s \geq 3 \) and \( n, m \geq 1 \) with \( r + m = s + n \) the automorphism groups \( \text{Aut}(\lambda(M_{r,m})) \) and \( \text{Aut}(\lambda(M_{s,n})) \) are isomorphic.

Conjecture 5.2. For any integer \( r \geq 2 \) and \( m \geq 1 \) the restriction operator \( R : \text{Aut}(\lambda(M_{r,m})) \to \text{Aut}(\lambda(M_{r,m}^2)) \), \( R : \psi \mapsto \psi|\lambda(M_{r,m}^2) \), has trivial range.
