MOMENTS ESTIMATORS AND OMNIBUS CHI-SQUARE TESTS FOR SOME USUAL PROBABILITY LAWS

GORGUI GNING †, ALADJI BABACAR NIANG ††, MODOU NGOM †††, AND GANE SAMB LO ††††

Abstract. For many probability laws, in parametric models, the estimation of the parameters can be done in the frame of the maximum likelihood method, or in the frame of moment estimation methods, or by using the plug-in method, etc. Usually, for estimating more than one parameter, the same frame is used. We focus on the moment estimation method in this paper. We use the instrumental tool of the functional empirical process (fep) in Lo (2016) to show how it is practical to derive, almost algebraically, the joint distribution Gaussian law and to derive omnibus chi-square asymptotic laws from it. We choose four distributions to illustrate the method (Gamma law, beta law, Uniform law and Fisher law) and completely describe the asymptotic laws of the moment estimators whenever possible. Simulations studies are performed to investigate for each case the smallest sizes for which the obtained statistical tests are recommendable. Generally, the omnibus chi-square test proposed here work fine with sample sizes around fifty.

1. Introduction

Parameter estimations are important steps in parametric statistical modeling. Estimators of parameters can be derived from the maximum likelihood approach, the plug-in methods, the moment methods, etc. Of course, by far Maximum Likelihood Estimators (MLE) are preferred because of the statistical meaning of its derivation. Moments estimators (ME)'s and (MLE)'s may exist without having closed-form expressions. When a MLE does not have a closed-from estimator, the ME is a backup solution for authors who wish to have a clear idea of the estimation and a quick and more controlled way of computation. Finding ME’s is an important step in modeling. However, deriving the related statistical tests is needed for accepting or rejecting hypotheses.

For more than two parameters, it is more practicable to join the individual normal asymptotic laws for each parameters into one chi-square asymptotic laws which is qualified as omnibus following the Jarque-Berra chi-square asymptotic law.

This motivates us to investigate asymptotic laws of ME’s estimators of as much as possible of usual and non-usual statistical laws. The found law should be validated by simulation studies before being proposed to potential users.

For a large review of asymptotic estimations and statistical tests, we refer to Van der Vaart (2000), Billingsley (1968), etc. Especially, for methods including functional empirical process, van der Vaart and Wellner (1996) is recommended.

However the main tool used here, but not limited to, is the function empirical process (fep) transformed into a instrument tools in Lo (2016) (see below). Let us begin by giving a few words on that tool and next basic notation.

In this paper, we used the fep tool to show direct and efficient ways for deriving asymptotic statistical tests for moment estimators for a selected set of four probability laws. Four these laws, all the computations are given in details. Computer codes for simulations are also provided. We could have treated more statistical distributions. However, we wanted this paper to be a model for researchers who need asymptotic statistical tests. Later, we
expect to compose a handbook which includes a great number of laws.

The paper is organized as follows. We will close this introductory section by describing the \textit{lqfep} tool in Subsection 1.1 and, in Section 1.2 by showing how to derive omnibus chi-square tests from the Gaussian asymptotic theorems for distributions of more than two parameters. In Section 2, we expose the asymptotic laws of the moments estimators of \textit{gamma}, \textit{uniform}, \textit{beta} and \textit{Fisher} distributions. The proofs and the implementation of the \textit{fep} tool on these distributions are stated in Section 4. In Section 3, we proceed to a simulation study on the asymptotic results and show that the omnibus chi-square tests work fine for small samples. The codes used for the simulations are stated in an appendix from page 27. The paper ends with conclusions and perspectives in Section 5.

1.1. \textbf{A brief reminder of the \textit{fep}.} Let $Z_1$, $Z_2$, ... be a sequence of independent copies of a random variable $Z$ defined on the same probability space with values on some metric space $(S,d)$. Define for each $n \geq 1$, the functional empirical process by

$$G_n(f) = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} (f(Z_i) - \mathbb{E}f(Z_i)),$$

where $f$ is a real and measurable function defined on $\mathbb{R}$ such that

$$\mathbb{V}_Z(f) = \int (f(x) - \mathbb{P}_Z(f))^2 d\mathbb{P}_Z(x) < \infty,$$

which entails

$$\mathbb{P}_Z(|f|) = \int |f(x)| \ d\mathbb{P}_Z(x) < \infty.$$

Denote by $\mathcal{F}(S) - \mathcal{F}$ for short -the class of real-valued measurable functions that are defined on $S$ such that (1.1) holds. The space $\mathcal{F}$, when endowed with the addition and the external multiplication by real scalars, is a linear space. Next, it remarkable that $G_n$ is linear on $\mathcal{F}$, that is for $f$ and $g$ in $\mathcal{F}$ and for $(a,b) \in \mathbb{R}^2$, we have

$$aG_n(f) + bG_n(g) = G_n(af + bg).$$
We have this result

**Lemma 1.** Given the notation above, then for any finite number of elements \( f_1, \ldots, f_k \) of \( S \), \( k \geq 1 \), we have

\[
\text{t}(\mathbb{G}_n(f_1), \ldots, \mathbb{G}_n(f_k)) \Rightarrow \mathcal{N}_k(0, \Gamma(f_i, f_j)_{1 \leq i, j \leq k}),
\]

where

\[
\Gamma(f_i, f_j) = \int (f_i - \mathbb{P}_Z(f_i))(f_j - \mathbb{P}_Z(f_j))d\mathbb{P}_Z(x), \quad 1 \leq i, j \leq k.
\]

**Proof.** It is enough to use the Cramér-Wold Criterion (see for example Billingsley (1968), page 45), that is to show that for any \( a = (a_1, \ldots, a_k) \in \mathbb{R}^k \), by denoting \( T_n = (\mathbb{G}_n(f_1), \ldots, \mathbb{G}_n(f_k)) \), we have \( < a, T_n > \Rightarrow < a, T > \) where \( T \) follows the \( \mathcal{N}_k(0, \Gamma(f_i, f_j)_{1 \leq i, j \leq k}) \) law and \( < \cdot, \cdot > \) stands for the usual product scalar in \( \mathbb{R}^k \). But, by the standard central limit theorem in \( \mathbb{R} \), we have

\[
< a, T_n > = \mathbb{G}_n \left( \sum_{i=1}^k a_i f_i \right) = \sum_{i=1}^k a_i \mathbb{G}_n(f_i) \Rightarrow N(0, \sigma^2_\infty),
\]

where, for \( g = \sum_{1 \leq i \leq k} a_i f_i \),

\[
\sigma^2_\infty = \int (g(x) - \mathbb{P}_Z(g))^2 \, d\mathbb{P}_Z(x)
\]

and this easily gives

\[
\sigma^2_\infty = \sum_{1 \leq i, j \leq k} a_i a_j \Gamma(f_i, f_j),
\]

so that \( N(0, \sigma^2_\infty) \) is the law of \( < a, T > \). The proof is finished.
1.2. Main notations in the fep. In the context of this paper, we use univariate samples $X, X_1, X_2, \ldots, X_n, n \geq 1$, with common cumulative distribution function (cdf) $F_X = F$, defined on the same probability space $(\Omega, \mathcal{A}, \mathbb{P})$. We will usually need the cumulants $m_k$ and the centered moments $\mu_k$ defined by

$$m_k = \mathbb{E}X^k, \quad \mu_k = \mathbb{E}(X - \mathbb{E}(X))^k, \quad k \geq 1$$

and their plug-in estimators

$$\bar{X}_{k,n} = \frac{1}{n} \sum_{j=1}^{n} X_j^k, \quad \bar{\mu}_{k,n} = \frac{1}{n} \sum_{j=1}^{n} (X_j - \bar{X}_n)^k, \quad k \geq 1$$

with the special case of the empirical mean $\bar{X}_{k,n} = \bar{X}_n$. Also the standard variance

$$S_n^2 = \frac{1}{n - 1} \sum_{j=1}^{n} (X_j - \bar{X}_n)^2$$

will be preferred to the plug-in estimator $\bar{\mu}_{2,n}$ of $\sigma^2 = \text{Var}(X)$. We suppose that any moment of order $k \geq 1$ exists whenever it is used.

The moment method in a parametric estimation related to the studied random variable having $\ell \geq 1$ parameters $(\theta_1, \ldots, \theta_\ell)$ and which generates the sample $\{X_1, \ldots, X_n\}$ consisted in simultaneously solving $\ell$ equations, each of these equations $r \in \{1, \ldots, \ell\}$ being the equality between a cumulant or a moment of order $k_r$ and the corresponding plug-in estimator of the same order $h_r$ where all order $k_j$ are pairwise distinct. In general, it is simpler to take equations between the $\ell^{th}$ first cumulants or moments. The solution, whenever exists and statistics of the empirical cumulant or moments,

$$\hat{\theta}_n = (\hat{\theta}_{1,n}, \ldots, \hat{\theta}_{\ell,n})$$

is the vector moment estimator (ME).

Once the ME’s are found, we will need the joint asymptotic law of the vector $\hat{\theta}_n$. The tool of the fep will greatly help in that target. We will go beyond and derive chi-square tests as much as possible.
The rest of the paper is organized as follows...

1.3. **Chi-square law derivation.** We are going to show how to derive asymptotic chi-square laws from moment estimators for at least two parameters. In each case below, we treat a two-parameter estimation problem. Suppose that the two parameters are denoted by $a$ and $b$ and their moment estimators are denoted by $\hat{a}_n$ and $\hat{b}_n$, $n \geq 2$. We will get in each case a first law in the form: as $n \to +\infty$,

\[
\begin{pmatrix} \sqrt{n}(\hat{a}_n - a) \\ \sqrt{n}(\hat{b}_n - b) \end{pmatrix} \overset{\mathcal{L}}{\to} Z, \quad Z \sim \mathcal{N}_2(0, \Sigma),
\]

where $\sigma_1^2 = \Sigma_{1,1}$, $\sigma_2^2 = \Sigma_{2,2}$ and $\sigma_{12} = \Sigma_{1,2}$. From usual properties of Gaussian vectors, we have that, whenever $\det(\Sigma) = \sigma_1^2 \sigma_2^2 - \sigma_{12}^2 \neq 0$,

\[
Z^T \Sigma^{-1} Z \sim \chi^2_2.
\]

(See for example Lo (2018), Proposition 12, page 150). By the continuous mapping theorem (see for example Lo et al. (2016), Proposition 03, page 34 ), we will have, as $n \to +\infty$,

\[
Q_n = \begin{pmatrix} \sqrt{n}(\hat{a}_n - a) \\ \sqrt{n}(\hat{b}_n - b) \end{pmatrix} \Sigma^{-1} \begin{pmatrix} \sqrt{n}(\hat{a}_n - a) \\ \sqrt{n}(\hat{b}_n - b) \end{pmatrix} \overset{\mathcal{L}}{\to} \chi^2_2,
\]

which, as $n \to +\infty$, leads to

\[
Q_n \overset{\mathcal{L}}{= \frac{n}{\sigma_1^2 \sigma_2^2 - \sigma_{12}^2}} \left[ \sigma_2^2(\hat{a}_n - a)^2 + \sigma_1^2(\hat{b}_n - b)^2 - 2\sigma_{12}(\hat{a}_n - a)(\hat{b}_n - b) \right] \sim \chi^2_2.
\]

(1.4)

So, below, for each treated case, we will state two results according to (1.3) and (1.4).
2. Asymptotics related to moments estimators

In that section, we are going to treat the following probability laws:

\begin{align*}
(1) & \quad X \sim \gamma(a, b), \\
(2) & \quad X \sim \beta(a, b), \\
(3) & \quad X \sim U(a, b) \text{ and } \\
(4) & \quad X \sim F(a, b)
\end{align*}

These results are meant to be interesting examples for other cases not handing here. We stress that the techniques in Lo (2016) will be extensively used in the following.

2.1. **Gamma laws** $\gamma(a, b)$ of parameters $a > 0$, $b > 0$. The gamma law $\gamma(a, b)$ has the probability density function \( pdf \)

\[ f(x) = \frac{b^a}{\Gamma(a)} x^{a-1} \exp(-bx)1_{(x \geq 0)} \text{ with } \Gamma(a) = \int_{a}^{+\infty} x^{a-1} \exp(-x) \, dx. \]

The \( k \)-th cumulant \( (k \geq 1) \) is given by

\[ \mathbb{E}X = \frac{a}{b} \text{ and } \mathbb{E}X^k = \frac{a}{b^k} \prod_{j=1}^{k-1} (a + j) \text{ for } k \geq 2, \]

and the variance is

\[ \sigma^2 = \text{Var} (X) = \frac{a}{b^2}. \]

The moment estimators $\hat{a}_n$ and $\hat{b}_n$ are solution of the equations $a/b = \bar{X}_n$ and $ab^{-2} = S_n^2$. We get

\[ (\hat{a}_n, \hat{b}_n) = \left( \frac{X_n^2}{S_n^2}, \frac{X_n}{S_n^2} \right). \]

Here are the results for the $\gamma$-law of parameters $a > 0$ and $b > 0$.

**Theorem 1.** We have

\[ \sqrt{n}(\hat{a}_n - a, \hat{b}_n - b) \rightsquigarrow N_2(0, \Sigma), \]

with
\[ \Sigma_{1,1} = \text{Var}(H(X)), \quad \Sigma_{2,2} = \text{Var}(L(X)), \quad \Sigma_{1,2} = \text{Cov}(H(X), L(X)) \]

and
\[
H = \frac{2\mu (\sigma^2 + 1)}{\sigma^4} h_1 + \frac{\mu^2}{\sigma^4} h_2, \\
L = \left( \frac{\sigma^2 + 2\mu}{\sigma^4} \right) h_1 - \frac{\mu}{\sigma^4} h_2.
\]

We also have
\[
Q_n = \frac{n}{\text{det}(\Sigma)} \left[ \Sigma_{2,2} (\hat{a}_n - a)^2 + \Sigma_{1,1} (\hat{b}_n - b)^2 - 2\Sigma_{1,2} (\hat{a}_n - a)(\hat{b}_n - b) \right] \rightsquigarrow \chi^2_2.
\]

2.2. **Beta law** \(\beta(a,b)\) **of parameters** \(a > 0, b > 0\). The Beta law has the following probability distribution function
\[
f(x) = \frac{x^{a-1} (1-x)^{b-1}}{B(a,b)}, \quad x > 0.
\]

Where
\[
B(a,b) = \frac{\Gamma(a) \Gamma(b)}{\Gamma(a+b)}.
\]

The expectation is given by
\[
\mathbb{E}(X) = \frac{a}{a+b}
\]

and the second moment order cumulant is given by
\[
\mathbb{E}(X^2) = \frac{a(a+1)}{(a+b)(a+b+1)}.
\]

The moment estimators \(\hat{a}_n\) and \(\hat{b}_n\) are solutions of the equations \(a/(a+b) = \bar{X}_n\) and \(a(a+1)/(a+b)(a+b+1) = \bar{X}_n^2\). We get
\[
(\hat{a}_n, \hat{b}_n) = \left( \frac{\bar{X}_n (X_n - \bar{X}_n^2)}{\bar{X}_n^2 - \bar{X}_n^2}, \frac{(1 - \bar{X}_n)(X_n - \bar{X}_n^2)}{\bar{X}_n^2 - \bar{X}_n^2} \right)
\]

Here are the results for the \( \beta \)-law of parameters \( a > 0 \) and \( b > 0 \).

**Theorem 2.** We have
\[
\sqrt{n}(\hat{a}_n - a, \hat{b}_n - b) \sim N_2(0, \Sigma),
\]
with
\[
\Sigma_{1,1} = \text{Var}(H(X)), \quad \Sigma_{2,2} = \text{Var}(L(X)), \quad \Sigma_{1,2} = \text{Cov}(H(X), L(X)),
\]
\[
H = \frac{\sigma^2 (2\mu - m_2) + 2\mu^2 (\mu - m_2)}{\sigma^4} h_1 - \frac{\sigma^2 \mu + \mu (\mu - m_2)}{\sigma^4} h_2
\]
and
\[
L = \frac{\sigma^2 (m_2 - 2\mu + 1) + 2\mu(1 - \mu)(\mu - m_2)}{\sigma^4} h_1 + \frac{(\mu - 1) (\sigma^2 + \mu - m_2)}{\sigma^4} h_2.
\]

We also have the following asymptotic \( \chi^2 \) result
\[
Q_n = \frac{n}{\det(\Sigma)} \left[ \Sigma_{2,2}(\hat{a}_n - a)^2 + \Sigma_{1,1}(\hat{b}_n - b)^2 - 2\Sigma_{1,2}(\hat{a}_n - a)(\hat{b}_n - b) \right] \sim \chi^2_2.
\]

2.3. **The Uniform law of parameters** \( U(a, b) \), \( a > 0 \) and \( b > a \). The probability distribution function of the uniform law is given by
\[
f(x) = \frac{1}{b - a}, \quad x \in [a, b].
\]

Its expectation is
\[
\mathbb{E}(X) = \frac{a + b}{2}.
\]

The variance is
\[
\text{Var}(X) = \frac{(b - a)^2}{12}.
\]

The moment estimators are the solutions of the equations

\[
(\hat{a}_n, \hat{b}_n) = \left( \frac{X_n - \lambda (S_n^2)^{1/2}}{2}, \frac{X_n + \lambda (S_n^2)^{1/2}}{2} \right)
\]

where \( \lambda = 12^{1/2}/2 \).

Here are the results for the Uniform-law.

**Theorem 3.** We have

\[
\sqrt{n}(\hat{a}_n - a, \hat{b}_n - b) \rightsquigarrow N_2(0, \Sigma),
\]

with

\[
\Sigma_{1,1} = \text{Var}(H(X)), \quad \Sigma_{2,2} = \text{Var}(L(X)), \quad \Sigma_{1,2} = \text{Cov}(H(X), L(X)),
\]

where

\[
H = \left( 1 + \frac{\lambda \mu}{\sigma} \right) h_1 - \frac{\lambda}{2\sigma} h_2
\]

and

\[
L = \left( 1 - \frac{\lambda \mu}{\sigma} \right) h_1 + \frac{\lambda}{2\sigma} h_2,
\]

where \( \lambda = 12^{1/2}/2 \).

We also have

\[
Q_n = \frac{n}{\text{det}(\Sigma)} \left[ \Sigma_{2,2}(\hat{a}_n - a)^2 + \Sigma_{1,1}(\hat{b}_n - b)^2 - 2\Sigma_{1,2}(\hat{a}_n - a)(\hat{b}_n - b) \right] \rightsquigarrow \chi_2^2.
\]
2.4. **Fisher law** $\mathcal{F}(a, b)$ of parameters $a > 0$ and $b > 0$. For a Fisher law with $a$ and $b$ degrees of freedom, the parameters are supposed to be integers. But in the general case, the probability density function has the same form and is associated to the quotient of two independent random variables $Z_1/Z_2$, where $Z_1 \sim \gamma(a, 1/2)/a$ and $Z_2 \sim \gamma(b, 1/2)/b$, where $a$ and $b$ are positive. The pdf is expressed as follows:

$$f(x) = \frac{a^{1/2}b^{1/2}\Gamma\left(\frac{a+b}{2}\right)x^{a/2-1}}{\Gamma(a/2)\Gamma(b/2)(b+ax)^{(a+b)/2}}, x > 0.$$ 

The expectation is given by

$$\mathbb{E}(X) = \frac{b}{b-2} = \overline{X}_n.$$ 

The variance is given by

$$\text{Var}(X) = \frac{2b^2(a+b-2)}{a(b-2)^2(b-4)} = S_n^2, \ b > 4.$$ 

The moment estimators are solutions of the equations

$$\left(\hat{a}_n, \ \hat{b}_n\right) = \left(\frac{2\overline{X}_n^2}{S_n^2(2-\overline{X}_n) - \overline{X}_n^2(\overline{X}_n - 1)}, \ \frac{2\overline{X}_n}{\overline{X}_n - 1}\right).$$

Here are the results for the Fisher-law.

**Theorem 4.** We have

$$\sqrt{n}(\hat{a}_n - a, \ \hat{b}_n - b) \rightsquigarrow \mathcal{N}_2(0, \Sigma),$$

with

$$\Sigma_{1,1} = \text{Var}(H(X)), \ \Sigma_{2,2} = \text{Var}(L(X)), \ \Sigma_{1,2} = \text{Cov}(H(X), L(X)),$$

where

$$H = \frac{2\mu(2-\mu)}{\beta}h_1 - \frac{2\mu^2(2-\mu)}{\beta^3}h_2$$

with
\[
\beta = \sigma^2 + 2\mu(2 - \mu) - \mu(3\mu - 2)
\]

and where

\[
L = -\frac{2}{(\mu - 1)^2} h_1.
\]

We also have

\[
Q_n = \frac{n}{\text{det}(\Sigma)} \left[ \Sigma_{2,2}(\hat{a}_n - a)^2 + \Sigma_{1,1}(\hat{b}_n - b)^2 - 2\Sigma_{1,2}(\hat{a}_n - a)(\hat{b}_n - b) \right] \rightsquigarrow \chi^2_2.
\]

3. Simulations

We are going to describe our simulation works for one of studied distributions. Next we will explain their outputs and their interpretations. Finally, we will display results for all cases. Important scripts will be posted in the appendix 27.

3.1. Simulation works. In all cases, we estimate two parameters. In the case of the \(\gamma(a,b)\) law, the moment estimators are denoted by \(achap\) and \(bchap\). We will have three parts.

A- Computing the exact moments and other coefficients of the estimators.

(a) Before proceeding to the Monte-Carlo method, we have to computed the function \(H\) and \(L\), denoted as \(bigH\) and \(bigL\).

(b) We proceed to numerical methods for computing \(\mathbb{E}H(X)\), \(\text{sigmaHexaC} = \text{Var}(\mathbb{E}H(X))\), \(\mathbb{E}L(X)\), \(\text{sigmaLexaC} = \text{Var}(\mathbb{E}L(X))\) and the exact co-variance \(\text{SigmaHLexa} = \text{Cov}(\mathbb{E}H(X), \mathbb{E}L(X))\), where \(X\) stands for random variable with the studied law (here a \(\gamma(a,b)\) law). The trapezoidal method algorithm is used for all integral computations here.

In page 27, the related script is given under the title A1 - Computing exact coefficients. Table gives exact values of the variances for different
Table 1. Over/under estimation of variances and covariances of estimators with respect to the true values for \((a, b) = (2, 3)\)

| (a,b)       | (2,3) | (3,10) | (10,3) |
|-------------|-------|--------|--------|
| \(\sigma_{\text{Hexa}}\) | 7.78  | 107.08 | 63.08  |
| \(\sigma_{\text{Lexa}}\) | 7.37  | 76.58  | 16.99  |
| \(\sigma_{\text{HLexa}}\) | 40.3  | 7.985.01 | 1006.95 |
| Correlation | 69.76%| 98.11% | 93.95% |

pairs \((a, b)\).

**B- Monte-Carlo estimation.**

(a) Fix a sample size \(n \geq 2\). Fix values to \(a\) and \(b\).

(b) Fix the number of repetitions \(B = 1000\) (big enough to ensure the stability of outcomes).

(c) At each repetition \(j \in \{1, \cdots, B\}\), we generate an sample of \(X\) of size \(n\). Next

1. \(DA[j] = \sqrt{n}(achap - a)\)
2. \(DB[j] = \sqrt{n}(bchap - a)\)
3. \(VH[j] = sd(bigH(X))\)
4. \(VL[j] = sd(bigL(X))\)
5. \(VHL[j] = cov(bigH(X), bigL(X))\)

In page 28, the related script is under the title **A2- Script Monte Carlo works.**

**C- Computing the empirical moments and other coefficients.**

(a) Now, we have: (1) an estimate of \(\Sigma_{1,1}\) by the square of the average of the vector \(VH\), (2) an estimate of \(\Sigma_{2,2}\) by the square of the average of the vector \(VH\) and (3) an estimate of \(\Sigma_{1,2}\) by the average of the vector \(VHL\). We denote them as \(\text{SigmaHEMP, SigmaLEMP and SigmaHLEMP.}\)

(b) We also have: (1) an estimate of \(\Sigma_{1,1}\) by empirical variance of \(DA\), (2) an estimate of \(\Sigma_{2,2}\) by empirical variance of \(DB\) and (3) an estimate of \(\Sigma_{1,2}\) by

\]
\[
DB_3[j] = \sqrt{\frac{n}{\Sigma_{\text{LSAMP}}}(b \text{chap} - b)} \approx N(0,1).
\]

In page 29, the scripts **A4- Computations of the p-values**, for each parameter $a$ and $b$, we compute the empirical p-values for each sequence, as the frequency of element of the sequence exceeding 1.96. The test is satisfactory if that $p$ value is less of around 5%. The different p-values for $a = 2$ and $b = 3$ are given for different values of $n$ in Table 6.

To test the quality of the normal approximations, we display the QQ-plots and the Parzen estimators graphs for each parameter in Fig 1 (QQ-plots and Parzen estimators related to the parameter $a$ for $n=50$, according to the type of estimation of the coefficients), in Fig 2 (QQ-plots and Parzen estimators related to the parameter $b$ for $n=50$, according to the type of estimation of the coefficients), in Fig 3 (QQ-plots and Parzen estimators related to the parameter $a$ for $n=300$, according to the type of estimation of the coefficients) and in Fig 4 (QQ-plots and Parzen estimators related to the parameter $b$ for $n=300$, according to the type of estimation of the coefficients) in Appendix C (Page 32).

**(E) Omnibus test.** We mean by omnibus test that the combine both test into a chi-square test as in Part (b) of each of Theorems 4, 3, 2. Depending on the use of exact values, empirical values or sample values of the
Table 7. QNE, QNEMP and QNSAMP according to the size $n$ for $a = 10$ and $b = 3$

| cases | n=50  | n=100 | n=200 | n=300 | n=1000 |
|-------|-------|-------|-------|-------|--------|
| QNE   | 1.2%  | 0.1%  | 0.02% | 0.001%| 0.01%  |
| QNEMP | 0%    | 0%    | 0%    | 0%    | 0.8%   |
| QNSAMP| 0.6%  | 0.1%  | 0.3%  | 0.01% | 0.2%   |

(variance of co-variances, we have three statistics that can be used each for the chi-square test:

$$QExa[j] = \frac{n}{\text{det}HL} \left( \text{sigmaLE} x \text{C}(\text{achap[j]} - a)^2 + \text{sigmaHE} x \text{C}(\text{bchap[j]} - b)^2 - 2 \times \text{sigmaHL} e \text{xa}(\text{achap[j]} - a) \times (\text{bchap[j]} - b) \right) \sim \chi^2_1$$

$$QEMPDB[j] = \frac{n}{\text{det}HLEMP} \left( (\text{sigmaLE} M \text{P}^2)(\text{achap[j]} - a)^2 + (\text{sigmaHE} M \text{P}^2)(\text{bchap[j]} - b)^2 - 2 \times \text{sigmaHLE} M \text{P}(\text{achap[j]} - a) \times (\text{bchap[j]} - b) \right) \sim \chi^2_1$$

$$QEMPDB[j] = \frac{n}{\text{det}L\text{SAMP}} \left( (\text{sigmaL} S\text{AMP}^2)(\text{achap[j]} - a)^2 + (\text{sigmaH} S\text{AMP}^2)(\text{bchap[j]} - b)^2 - 2 \times \text{sigmaHL} S\text{AMP}(\text{achap[j]} - a) \times (\text{bchap[j]} - b) \right) \sim \chi^2_1$$

Table 7 provides the p-value related to the omnibus test for different sizes according to the estimations of the coefficients used. The related test is given in the script under the title A5- p-values for the omnibus statistical test in page 30.

(D) - Conclusions of recommendations from simulations. The simulation studies show that the omnibus statistical test is very good even for sizes as small as $n = 50$ for all estimations of the coefficients in the test statistics. When we do Gaussian separate tests for $a$ and $b$, the outcomes are remarkable in the use the variance and covariance of $\sqrt{n}(\hat{a}_n - a)$ and
\( \sqrt{n}(\hat{b}_n - b) \). This is observable in the QQ-plots, the Parzen graphs and in the p-values of the tests. The separate tests seem to recommend the tests when \( n \) is bigger than 100. But, definitively, the omnibus works fine for small sizes as \( n = 11 \) with p-values 5.6\%, 0\%, 1.7\%.

We strongly suggest to no use the tests with empirical estimations of the variance and covariance which lead to severe under or over estimation.

4. Proofs of Theorems

Here, we provide the computations for each treated probability law.

4.1. **Gamma Law** \( \gamma(a, b) \) of parameters \( a > 0, b > 0 \). We have

\[
(4.1) \quad \overline{X}_n = \mu + n^{-1/2}G_n(h_1)
\]

and

\[
(4.2) \quad S^2_n = \frac{1}{n-1} \left[ \sum_{j=1}^{n} X_j^2 - n\overline{X}_n^2 \right]
\]

\[
(4.3) \quad = \frac{n}{n-1} \left[ \frac{1}{n} \sum_{j=1}^{n} X_j^2 - \overline{X}_n^2 \right]
\]

\[
(4.4) \quad = \frac{n}{n-1} \left[ \overline{X}_n^2 - \overline{X}_n^2 \right].
\]

By the delta method,

\[
(4.5) \quad \overline{X}_n^2 = \mu^2 + n^{-1/2}G_n(2\mu h_1) + O_p\left(n^{-1/2}\right)
\]

and

\[
(4.6) \quad \overline{X}_n^2 = \frac{1}{n} \sum_{j=1}^{n} X_j^2 = m_2 + n^{-1/2}G_n(h_2).
\]

We know that

\[
\frac{n}{n-1} = \left( \frac{n-1}{n} \right)^{-1} = (1 - 1/n)^{-1} = 1 + O_p(1).
\]
Hence

\[(4.7) \quad S_n^2 = \sigma^2 + n^{-1/2} G_n (h_2 - 2\mu h_1) + O_p \left( n^{-1/2} \right). \]

Let us handle \( \hat{b}_n \). We have

\[ \hat{b}_n = \frac{X_n}{S_n^2}. \]

By equations (4.1), (4.7) and by lemma 11 in Lo (2016), we have

\[ \hat{b}_n = \frac{\mu}{\sigma^2} n^{-1/2} G_n \left( \frac{h_1}{\sigma^2} - \frac{\mu}{\sigma^4} (h_2 - 2\mu h_1) \right) + O_p \left( n^{-1/2} \right) \]

where

\[ L = \frac{h_1}{\sigma^2} - \frac{\mu}{\sigma^4} (h_2 - 2\mu h_1) = \left( \frac{\sigma^2 + 2\mu h_1}{\sigma^4} \right) h_1 - \frac{\mu^2}{\sigma^4} h_2 \]

Let us treat \( \hat{a}_n \). By combining equations (4.5), (4.7) and lemma 11 in Lo (2016), we get

\[ \hat{a}_n = \frac{\mu}{\sigma^2} n^{-1/2} G_n (H), \]

where

\[ H = \frac{2\mu}{\sigma^2} h_1 - \frac{\mu^2}{\sigma^4} (h_2 - 2\mu h_1) = \frac{2\mu \sigma^2}{\sigma^4} h_1 - \frac{\mu^2}{\sigma^4} h_2 \]

\[ = \frac{2\mu (\sigma^2 + 1)}{\sigma^4} h_1 - \frac{\mu^2}{\sigma^4} h_2. \]
4.2. **Beta Law \( \beta(a, b) \) of parameters \( a > 0, b > 0 \).** The moment estimators \( \hat{a}_n \) and \( \hat{b}_n \) are solutions of the equations

\[
\hat{a}_n = \frac{\bar{X}_n (\bar{X}_n - \bar{X}_n^2)}{\bar{X}_n^2 - \bar{X}_n^2}
\]

and

\[
\hat{b}_n = \frac{(1 - \bar{X}_n) (\bar{X}_n - \bar{X}_n^2)}{\bar{X}_n^2 - \bar{X}_n^2}.
\]

We have

(4.8) \[
\bar{X}_n = \mu + n^{-1/2}G_n (h_1)
\]

and

(4.9) \[
\bar{X}_n^2 = m_2 + n^{-1/2}G_n (h_2).
\]

By the delta method, we have

(4.10) \[
\bar{X}_n^2 = \mu^2 + n^{-1/2}G_n (2\mu h_1) + O_p \left( n^{-1/2} \right)
\]

and

(4.11) \[
1 - \bar{X}_n = 1 - \mu - n^{-1/2}G_n (h_1) = 1 - \mu + n^{-1/2}G_n (-h_1).
\]

By combining equations (4.12) and (4.13), we have

\[
A_n = \bar{X}_n - \bar{X}_n^2 = \mu - m_2 + n^{-1/2}G_n (h_1 - h_2).
\]

By combining equations (4.13) and (4.10), we have

\[
B_n = \bar{X}_n^2 - \bar{X}_n = m_2 - \mu^2 + n^{-1/2}G_n (h_2) - n^{1/2}G_n (2\mu h_1)
= m_2 - \mu^2 + n^{-1/2}G_n (h_2 - 2\mu h_1) + O_p \left( n^{-1/2} \right).
\]
Hence
\[ \hat{a}_n = \frac{C_n}{B_n} \]
with
\[ C_n = \bar{X}_n \times A_n \]
\[ = \mu (\mu - m_2) + n^{-1/2} G_n \left( ((\mu h_1 - \mu h_2) + (\mu - m_2) h_1) + O_p \left( n^{-1/2} \right) \right). \]

Then
\[ C_n = \mu (\mu - m_2) + n^{-1/2} G_n \left( H_2 \right) + O_p \left( n^{-1/2} \right), \]
where
\[ H_2 = (\mu h_1 - \mu h_2) + (\mu - m_2) h_1 \]
\[ = (2\mu - m_2) h_1 - \mu h_2. \]

Hence
\[ \hat{a}_n = \frac{\mu (\mu - m_2) + n^{-1/2} G_n \left( H_2 \right) + O_p \left( n^{-1/2} \right)}{m_2 - \mu^2 + n^{-1/2} G_n \left( h_2 - 2\mu h_1 \right) + O_p \left( n^{-1/2} \right)}. \]

By lemma 11 in Lo (2016), we get
\[ \hat{a}_n = \frac{\mu (\mu - m_2) + n^{-1/2} G_n \left( H \right) + O_p \left( n^{-1/2} \right)}{m_2 - \mu^2 + n^{-1/2} G_n \left( h_2 - 2\mu h_1 \right) + O_p \left( n^{-1/2} \right)}, \]
where
\[ H = \frac{\sigma^2 (2\mu - m_2) + 2\mu^2 (\mu - m_2)}{\sigma^4} h_1 - \frac{\sigma^2 \mu + \mu (\mu - m_2)}{\sigma^4} h_2. \]

Let us handle now \( \hat{b}_n \).

Remind that
\[ \hat{b}_n = \frac{(1 - \bar{X}_n) (\bar{X}_n - X_n^2)}{X_n^2 - \bar{X}_n^2} = \frac{B_1 (n)}{B_2 (n)}. \]
Thanks to the previous calculus, we have

\[
\hat{b}_n = \frac{(1 - \mu) (\mu - m_2)}{\sigma^2} + n^{-1/2} G_n (L) + O_p \left( n^{-1/2} \right),
\]

where

\[
L = \frac{\sigma^2 (m_2 - 2 \mu + 1) + 2 \mu (1 - \mu) (\mu - m_2)}{\sigma^4} h_1 + \frac{(\mu - 1) (\sigma^2 + \mu - m_2 - m_1)}{\sigma^4} h_2.
\]

4.3. **Uniform Law** \( \mathcal{U}(a, b) \), of parameters \( a > 0 \) and \( b > a \). We have

\[
(4.12) \quad \overline{X}_n = \mu + n^{-1/2} G_n \left( h_1 \right)
\]

and

\[
(4.13) \quad \overline{X}_n^2 = m_2 + n^{-1/2} G_n \left( h_2 \right).
\]

By combining equations (4.12) and (4.13), we have

\[
S_n^2 = \sigma^2 + n^{-1/2} G_n \left( h_2 - 2 \mu h_1 \right).
\]

By the delta method, we have

\[
\left( S_n^2 \right)^{1/2} = \sigma + n^{-1/2} G_n \left( \frac{1}{2\sigma} (h_2 - 2 \mu h_1) \right) + O_p \left( n^{-1/2} \right).
\]

So

\[
a_n = \mu - \lambda \sigma + n^{-1/2} G_n \left( \left( h_1 - \frac{\lambda}{2\sigma} (h_2 - 2 \mu h_1) \right) \right) + O_p \left( n^{-1/2} \right)
\]

\[
= \mu - \lambda \sigma + n^{-1/2} G_n \left( L \right) + O_p \left( n^{-1/2} \right),
\]

with

\[
L = \left( 1 + \frac{\lambda \mu}{\sigma} \right) h_1 - \frac{\lambda}{2\sigma} h_2.
\]

By using the same technique, we have
\( \hat{b}_n = \mu - \lambda \sigma + n^{-1/2}G_n(H) + O_p\left(n^{-1/2}\right), \)

where

\[
H = \left(1 - \frac{\lambda \mu}{\sigma}\right)h_1 + \frac{\lambda}{2\sigma}h_2.
\]

4.4. **Fisher Law** \( \mathcal{F}(a, b) \) of parameters \( a \) and \( b \). The moment estimators are defined below. The first moment estimator is

(4.14) \[
\hat{b} = \frac{2\bar{X}_n}{\bar{X}_n - 1} \\
= \frac{2\mu + n^{-1/2}G_n(2h_1)}{\mu - 1 + n^{-1/2}G_n(-h_1)} \\
= \frac{2\mu}{\mu - 1} + n^{-1/2}G_n(L) + o_p(n^{-1/2}),
\]

where

\[
L = \frac{2h_1}{\mu - 1} - \frac{2\mu}{(\mu - 1)^2}h_1 \\
= -\frac{2}{(\mu - 1)^2}h_1.
\]

The second estimator is given by

\[
a = \frac{2b^2(b - 2)}{S^2(b - 2)^2(b - 4) - 2b^4}.
\]

By equation (4.14), we know that

\[
b = \frac{2\bar{X}_n}{\bar{X}_n - 1}.
\]

So we have,
\[ b - 2 = \frac{2\bar{X}_n}{X_n - 1} - 2 = \frac{2}{X_n - 1}, \]
\[ b - 4 = \frac{2\bar{X}_n}{X_n - 1} - 4 = \frac{-2\bar{X}_n + 4}{X_n - 1}. \]

Hence

\[ \hat{a} = \frac{16\bar{X}^2_n}{8S^2(2 - \bar{X}_n) - 8\bar{X}^2_n(X_n - 1)} \]
\[ = \frac{2\bar{X}^2_n}{S^2(2 - X_n) - \bar{X}^2_n(X_n - 1)}. \]

From (4.14), we have

\[ S_n^2 = \sigma^2 + n^{-1/2}G_n(h_2 - 2\mu h_1) + o_{P(n^{-1/2})}. \]

Further, we have

\[ 2 - \bar{X}_n = 2 - \mu + n^{-1/2}G_n(-h_1) \]

\[ S_n^2(2 - \bar{X}_n) = \sigma^2(2 - \mu) + n^{-1/2}G_n(L_1) + o_{P(n^{-1/2})}, \]

where

\[ L_1 = -\sigma^2 h_1 + (2 - \mu)(h_2 - 2\mu h_1) \]
\[ = (\sigma^2 + 2\mu(2 - \mu))h_1 + (2 - \mu)h_2 \]

and

\[ \bar{X}^2_n = \mu^2 + n^{-1/2}G_n(2\mu h_1) + o_{P(n^{-1/2})}. \]

We also have

\[ \bar{X}_n - 1 = \mu - 1 + G_n(h_1) \]
\begin{equation}
(4.19) \quad \bar{X}_n^2 (\bar{X}_n - 1) = \mu^2 (\mu - 1) + n^{-1/2} G_n (L_2),
\end{equation}

where

\[ L_2 = \mu^2 h_1 + (\mu - 1)(2\mu h_1) = \mu(3\mu - 2)h_1. \]

So the denominator \((4.17)/(4.19)\) is expanded as

\[ \text{denom} = \frac{1}{(2 - \mu)\sigma^2 - \mu^2 (\mu - 1) + n^{-1/2} G_n (L_3) + o(\sigma^{n-1/2})}, \]

where

\[ L_3 = [\sigma^2 + 2\mu(2 - \mu) - \mu(3\mu - 2)]h_1 + (2 - \mu)h_2. \]

Hence

\[ \hat{a} = \frac{2\mu^2 + n^{-1/2} G_n (4\mu h_1) + o(\sigma^{n-1/2})}{\text{Denom}} = \frac{2\mu^2}{(2 - \mu)\sigma^2 - \mu^2 (\mu - 1) + n^{-1/2} G_n (H) + o(\sigma^{n-1/2})}, \]

where

\[ H = \frac{2\mu}{(2 - \mu)\sigma^2 - \mu^2 (\mu - 1)}h_1 - \frac{2\mu^2}{((2 - \mu)\sigma^2 - \mu^2 (\mu - 1))^2} L_3. \]

Let us set

\[ \alpha = (2 - \mu)\sigma^2 - \mu^2 (\mu - 1) \]
\[ \beta = \sigma^2 + 2\mu(2 - \mu) - \mu(3\mu - 2). \]

Then

\[ L_3 = \beta h_1 + (2 - \mu)h_2. \]

Hence
\[
H = \left( \frac{4}{\beta} \mu - \frac{2 \mu^2}{\beta} \right) h_1 - \frac{2 \mu^2 (2 - \mu)}{\beta^2} h_2 \\
= \frac{2 \mu (2 - \mu)}{\beta} h_1 - \frac{2 \mu^2 (2 - \mu)}{\beta^2} h_2.
\]

5. Conclusions and perspectives

Moment estimators for four statistical distributions been studied through their asymptotic Gaussian laws with the help of the \textit{jep} tool. Chi-square omnibus tests have been derived for each distribution. The results have been simulated and the chi-square tests revealed themselves efficient for small sample sizes. The R codes of the simulations are attached to the paper in an appendix. The main perspective is to develop a full chapter in with the study of a large number of distributions.

\textbf{Acknowledgment.} The authors Niang and Ngom express their thanks to Professor Lo for guidance, and moral and financial assistance.

A1 - Computing exact coefficients

\[ a=2; \quad b=3 \]
\[
\begin{align*}
(m1 &= \frac{a}{a+b}) \\
(m2 &= \frac{a(a+1)}{(a+b)(a+b+1)}) \\
\mu &= \frac{a}{b} \\
\sigma &= \frac{a}{b^2} \\
(a1 &= 2\mu\frac{(\sigma+1)}{(\sigma^2)}) \\
(a2 &= \frac{\mu^2}{\sigma^2}) \\
b1 &= \frac{(\sigma+2\mu)}{(\sigma^2)} \\
b2 &= \frac{\mu}{(\sigma^2)} \\
bigH &= \text{function}(x) \quad a1x+a2x^2 \\
bigL &= \text{function}(x) \quad b1x+b2x^2 \\
\end{align*}
\]

# calcul variance exacte avec l’algorithme Integrations
# appel de la fonction gamma
CC = (b^a)/gamma(a)

# Variance exacte
bigHFV = function(x) \( x^{(a-1)} \exp(-b \times x) \times \bigH(x) \times CC \)
bigLFV = function(x) \( x^{(a-1)} \exp(-b \times x) \times \bigL(x) \times CC \)
bigHFVC = function(x) \( x^{(a-1)} \exp(-b \times x) \times (\bigH(x)^2) \times CC \)
bigLFVC = function(x) \( x^{(a-1)} \exp(-b \times x) \times (\bigL(x)^2) \times CC \)

bigHInv = function(u) \( \bigH(qgamma(u, a, b)) \)
bigHInvC = function(u) \( \bigH(qgamma(u, a, b))^2 \)
bigLInv = function(u) \( \bigL(qgamma(u, a, b)) \)
bigLInvC = function(u) \( \bigL(qgamma(u, a, b))^2 \)
bigHLInv = function(u) \( \bigH(qgamma(u, a, b)) \times \bigL(qgamma(u, a, b)) \)

(moH1 = imhIntegD1(0, 1, bigHInv, 100, 0.0001))
(m2H1 = imhIntegD1(0, 1, bigHInvC, 100, 0.0001))
(sigmaHexaC = m2H1 - (moH1^2))

(moL1 = imhIntegD1(0, 1, bigLInv, 100, 0.0001))
(m2L1 = imhIntegD1(0, 1, bigLInvC, 100, 0.0001))
(sigmaLexaC = m2L1 - (moL1^2))
(moHL = imhIntegD1(0, 1, bigHLInv, 100, 0.0001))
(sigmaHLexa = moHL - (moH1*moL1))
(detHL = (sigmaHexaC*sigmaLexaC) - (sigmaHLexa^2))
A2- Script Monte Carlo works.

\[ \text{n=50} \]
\[ \text{B=1000} \]
\[ \text{DACHAP} \leftarrow \text{numeric (B)} \]
\[ \text{DBCHR} \leftarrow \text{numeric (B)} \]
\[ \text{sigmaVL} \leftarrow \text{numeric (B)} \]
\[ \text{sigmaVH} \leftarrow \text{numeric (B)} \]
\[ \text{sigmaVHL} \leftarrow \text{numeric (B)} \]

\[
\begin{align*}
\text{for (j in 1:B) \{ } \\
\text{X} &= \text{rgamma(n,a,b)} \\
\text{m1X} &= \text{mean(X)} \\
\text{varX} &= \text{var(X)} \\
\text{achap} &= ((\text{m1X})^2 / \text{varX}) \\
\text{bchap} &= ((\text{m1X}) / \text{varX}) \\
\text{sigmaVL}[j] &= \text{sd(\text{bigL(X)})} \\
\text{sigmaVH}[j] &= \text{sd(\text{bigH(X)})} \\
\text{sigmaVHL}[j] &= \text{cov(\text{bigH(X)}, \text{bigL(X)})} \\
\text{DACHAP}[j] &= \text{achap} \\
\text{DBCHR}[j] &= \text{bchap}
\}
\]

\[ \text{DA} = \sqrt{n} \times (\text{DACHAP} - a) \]
\[ \text{DB} = \sqrt{n} \times (\text{DBCHR} - b) \]
A3- Over/under estimations of variances and covariances

\[
\begin{align*}
\text{sigmaHEMP/sqrt (sigmaHexaC)} \\
\text{sigmaLEMP/sqrt (sigmaLexaC)} \\
\text{sigmaHLEMP/sigmaHLexa} \\
\text{sigmaHSAMP/sqrt (sigmaHexaC)} \\
\text{sigmaLSAMP/sqrt (sigmaLexaC)} \\
\text{sigmaHLSAMP/sigmaHexa}
\end{align*}
\]

A4- Computations of the p-values for statistical tests pour a et b.

\[
\begin{align*}
imhPvalue \left( DA/sqrt (sigmaHexaC), B, 1.96 \right) \\
imhPvalue \left( DA/sigmaHEMP, B, 1.96 \right) \\
imhPvalue \left( DA/sigmaHSAMP, B, 1.96 \right) \\
imhPvalue \left( DB/sqrt (sigmaLexaC), B, 1.96 \right) \\
imhPvalue \left( DB/sigmaLEMP, B, 1.96 \right) \\
imhPvalue \left( DB/sigmaLSAMP, B, 1.96 \right)
\end{align*}
\]

See Function imhPvalue, under the title:
B1-(a) Empirical tests from approximated Gaussian data, below
A5- p-values for the omnibus statistical test.

# Calculating exact coefficients

Estimation of the empirical and sample determinants

$$\text{detHLEMP} = (\sigma_{HEMP}^2 - \sigma_{12EMP}^2)$$

$$\text{detHLSAMP} = (\sigma_{HSAMP}^2 - \sigma_{12SAMP}^2)$$

Calculating the chi-square statistic with exact parameters

$$Q^\text{NE} = (\sigma_{LexaC}^2 (a_{chap} - a)^2 + \sigma_{HexaC}^2 (b_{chap} - b)^2)$$

$$Q^\text{NE} = 2 \sigma_{HLexa} (a_{chap} - a)(b_{chap} - b)$$

Calculating the chi-square statistic with empirical parameters

$$Q^\text{NEMP} = (\sigma_{LEMP}^2 (a_{chap} - a)^2 + \sigma_{HEMP}^2 (b_{chap} - b)^2)$$

$$Q^\text{NEMP} = 2 \sigma_{12EMP} (a_{chap} - a)(b_{chap} - b)$$

Calculating the chi-square statistic with estimated parameters

$$Q^\text{NSAMP} = (\sigma_{LSAMP}^2 (a_{chap} - a)^2 + \sigma_{HSAMP}^2 (b_{chap} - b)^2)$$

$$Q^\text{NSAMP} = 2 \sigma_{12SAMP} (a_{chap} - a)(b_{chap} - b)$$

# mean p-values using function in:

Empirical tests from approximated Chi-square data

```
pchisq(Q^\text{NE}, 2)
pchisq(Q^\text{NEMP}, 2)
pchisq(Q^\text{NSAMP}, 2)
```
B- Auxiliary Functions.

B1-(a) Empirical tests from approximated Gaussian data.

```r
size=1000
Z=rnorm(size, 0,1)
pt=1.96
j=0
pv=0

imhPvalue <- function(Z, size, pt){
  pv=0
  for (j in 1:size){
    if ( abs(Z[j]) > pt){
      pv=pv+1
    }
  }
  pv=100*pv/size
  return (pv)
}
```

B2-(b) Empirical tests from approximated Chi-square data.

```r
size=1000
df=2  // degrees of freedom
Z=rchisq(size, df)
th=0.05
j=0
pv=0

imhPvalueChisq <- function(Z, size, df, th){
  pv=0
  for (j in 1:size){
    if ( Z[j] > qchisq(1-th, df)){
      pv=pv+1
    }
  }
  pv=100*pv/size
  return (pv)
}
Figure 1. QQ-plots and Parzen estimators related to the parameter $a$ for $n=50$, according to the type of estimation of the coefficients.
Figure 2. QQ-plots and Parzen estimators related to the parameter $a$ for $n=50$, according to the type of estimation of the coefficients.
Figure 3. QQ-plots and Parzen estimators related to the parameter $a$ for $n=300$, according to the type of estimation of the coefficients.
Figure 4. QQ-plots and Parzen estimators related to the parameter $a$ for $n=300$, according to the type of estimation of the coefficients.
