Abstract—Recently, there has been significant interest in convex relaxations of the optimal power flow (OPF) problem. A semidefinite programming (SDP) relaxation globally solves many OPF problems. However, there exist practical problems for which the SDP relaxation fails to yield the global solution. Conditions for the success or failure of the SDP relaxation are valuable for determining whether the relaxation is appropriate for a given OPF problem. To move beyond existing conditions, which only apply to a limited class of problems, a typical conjecture is that failure of the SDP relaxation can be related to physical characteristics of the system. By presenting an example OPF problem with two equivalent formulations, this paper demonstrates that physically based conditions cannot universally explain algorithm behavior: The SDP relaxation fails for one formulation but succeeds in finding the global solution to the other formulation. Since these formulations represent the same system, success (or otherwise) of the SDP relaxation must involve factors beyond just the network physics. The lack of universal physical conditions for success of the SDP relaxation motivates the development of tighter convex relaxations capable of solving a broader class of problems. Tools from polynomial optimization theory provide a means of developing tighter relaxations. We use the example OPF problem to illustrate relaxations from the Lasserre hierarchy for polynomial optimization and a related “mixed semidefinite/second-order cone programming” hierarchy.

Index Terms—Optimal power flow, convex relaxation, global solution, power system optimization

I. INTRODUCTION

The optimal power flow (OPF) problem determines a minimum cost operating point for an electric power system subject to both network constraints and engineering limits. Typical objectives are minimization of losses or generation costs. The OPF problem is generally non-convex due to the non-linear power flow equations [1] and may have local solutions [2]. OPF solution techniques are therefore an ongoing research topic. Many techniques have been proposed, including successive quadratic programs, Lagrangian relaxation, and interior point methods [3]–[7].

There has been significant interest in convex relaxations of OPF problems. Convex relaxations lower bound the objective value, can certify infeasibility, and, in many cases, globally solve OPF problems. In contrast, traditional OPF solution methods may find the global optimum [8] but provide no guarantee of doing so, do not provide a measure of solution quality and cannot provably identify infeasibility. Convex relaxations thus have capabilities that supplement traditional techniques.

For radial systems that satisfy certain non-trivial technical conditions [9], a second-order cone programming (SOCP) relaxation is provably exact (i.e., the lower bound is tight and the solution provides the globally optimal decision variables). For more general OPF problems, a semidefinite programming (SDP) based Shor relaxation [10] is often exact [11]. Developing tighter and faster relaxations is an active research area [12]–[14].

Despite success in globally solving many practical OPF problems [11], [15], there are problems for which the SDP relaxation of [11] is not exact [2], [15]–[17]. There is substantial interest in developing sufficient conditions for exactness of the SDP relaxation. Existing conditions include requirements on power injection, voltage magnitude and line-flow limits, and either radial networks (typical of distribution systems), appropriate placement of controllable phase-shifting transformers, or a limited subset of mesh network topologies [9], [18].

The SDP relaxation globally solves many OPF problems which do not satisfy any known sufficient conditions [9], [18]. In other words, the set of problems guaranteed to be exact by known sufficient conditions is much smaller than the actual set of problems for which the relaxation is exact. This suggests the potential for developing less stringent conditions. It is natural to speculate that some physical characteristics of an OPF problem may govern such conditions. With solutions that are close to voltage collapse, this speculation is supported by several problems for which the SDP relaxation fails to be exact [17].

This paper presents an example that dampens enthusiasm for this avenue of research. We consider a small problem, first presented in [19], with two equivalent formulations. The SDP relaxation globally solves one formulation but fails to solve the other. Since both formulations represent the same system, strictly physically based conditions for the success of the relaxation cannot differentiate between these formulations. The feasible spaces of both problems illustrate why the SDP relaxation succeeds for one formulation but fails for the other.

The small example considered in this paper is relatively simple. In fact, this example “OPF” problem reduces to solving the minimum loss solution to power flow constraint equations for a specified set of power injections and voltage magnitudes. Thus, this example further demonstrates that the SDP relaxation may fail even for simple OPF problems.

The lack of universal, physically based conditions for de-
terminating success or failure of the SDP relaxation of [11] motivates the development of tighter convex relaxations. Recent research [20]–[24] exploits the fact that the OPF problem is a polynomial optimization problem in terms of the complex voltage phasors. Separating the complex voltages into real and imaginary parts yields a polynomial optimization problem in real variables. This facilitates the application of the Lasserre hierarchy of “moment” relaxations for real polynomial optimization problems, which take the from of SDPs [25]. The first-order moment relaxation is equivalent to the SDP relaxation of [11]. Higher-order moment relaxations thus generalize the SDP relaxation of [11].

Moment relaxations globally solve many problems for which the SDP relaxation of [11] is not exact [20]–[24]. We use the small example system to illustrate the moment relaxations, including exploration of the feasible space.

The ability of the moment relaxations to solve a broader class of OPF problems comes at a computational cost: the matrices grow rapidly with both relaxation order and system size. Ameliorating the former challenge, low relaxation or-

ders suffice for global solution of many problems. Several recent developments address the latter challenge. First, by exploiting sparsity and selectively applying the higher-order constraints to specific buses, loss-minimization problems with thousands of buses are computationally tractable [23], [24]. Second, rather than separating complex voltages into their real and imaginary parts, a hierarchy built directly from the complex formulation is computationally advantageous [26]. Third, a “mixed SDP/SCCP” hierarchy implements the first-order constraints with a SDP formulation, but the higher-order constraints are relaxed to a SOCP formulation. The less computationally intensive SOCP constraints often reduce solution times while still yielding global optima. The small example system is used to illustrate the mixed SDP/SCCP hierarchy.

This paper is organized as follows. Section II introduces the OPF problem. Section III describes the SDP relaxation of [11]. Section IV presents the example OPF problem which demonstrates that factors beyond the problem physics determine success or failure of the SDP relaxation. Sections V and VI provide the moment relaxations using SDP constraints and the mixed SDP/SCCP hierarchy, respectively, with the problem in Section IV providing an illustrative example. Section VII concludes the paper.

II. OPTIMAL POWER FLOW PROBLEM

We first present an OPF formulation in terms of rectangular voltage coordinates, active and reactive power injections, and apparent power line flow limits. Consider an n−bus system with nL lines, where N = {1, . . . , n} is the set of buses, G is the set of generator buses, and L is the set of lines. The network admittance matrix is Y = G + jB, where j denotes the imaginary unit. Let PDK + jQDK represent the active and reactive load demand and Vj = Vjk + jVjg the voltage phasors at each bus k ∈ N. Superscripts “max” and “min” denote specified upper and lower limits. Buses without generators have maximum and minimum generation set to zero.

\[ P_{lm} + jQ_{lm} \]

\[ V_i \]

\[ j2b_{h,lm} \]

\[ jb_{h,lm} \]

\[ V_m \]

\[ \tau_{lm} e^{j\theta_{lm}} : 1 \]

\[ f_{V_k} (V_d, V_q) := V_{d_k}^2 + V_{q_k}^2. \]  (1)

The power flow equations describe the network physics:

\[ f_{P_k} (V_d, V_q) := V_{d_k} \sum_{i=1}^{n} \left( G_{ki} V_{di} - B_{ki} V_{qi} \right) + V_{q_k} \sum_{i=1}^{n} \left( B_{ki} V_{di} + G_{ki} V_{qi} \right) + P_{DK}, \]  (2a)

\[ f_{Q_k} (V_d, V_q) := V_{d_k} \sum_{i=1}^{n} \left( -B_{ki} V_{di} - G_{ki} V_{qi} \right) + V_{q_k} \sum_{i=1}^{n} \left( G_{ki} V_{di} - B_{ki} V_{qi} \right) + Q_{DK}. \]  (2b)

Define a function for squared voltage magnitude:

\[ f_{C_k} (V_d, V_q) := c_{k2} (f_{P_k} (V_d, V_q))^2 + c_{k1} f_{P_k} (V_d, V_q) + c_{k0}. \]  (3)

We use a line model with an ideal transformer that has a specified turns ratio \( \tau_{lm} e^{j\theta_{lm}} : 1 \) in series with a \( \Pi \) circuit with series impedance \( R_{lm} + jX_{lm} \) (equivalent to an admittance of \( g_{lm} + jb_{h,lm} \)). This is (1).

\[ f_{P_{lm}} (V_d, V_q) := \left( V_{d_{lm}}^2 + V_{q_{lm}}^2 \right) g_{lm}/\tau_{lm}^2 \]

\[ + (V_{d_{lm}} V_{d_{rm}} + V_{q_{lm}} V_{q_{rm}}) \left( b_{lm} \sin (\theta_{lm}) - g_{lm} \cos (\theta_{lm}) \right) /\tau_{lm}, \]

\[ + (V_{d_{lm}} V_{q_{rm}} - V_{q_{lm}} V_{d_{rm}}) \left( g_{lm} \sin (\theta_{lm}) + b_{lm} \cos (\theta_{lm}) \right) /\tau_{lm}, \]  (4a)

\[ f_{Q_{lm}} (V_d, V_q) := -\left( V_{d_{lm}}^2 + V_{q_{lm}}^2 \right) b_{lm} /\tau_{lm}^2 \]

\[ + (V_{d_{lm}} V_{d_{rm}} + V_{q_{lm}} V_{q_{rm}}) \left( b_{lm} \cos (\theta_{lm}) + g_{lm} \sin (\theta_{lm}) \right) /\tau_{lm}, \]

\[ + (V_{d_{lm}} V_{q_{rm}} - V_{q_{lm}} V_{d_{rm}}) \left( g_{lm} \cos (\theta_{lm}) - b_{lm} \sin (\theta_{lm}) \right) /\tau_{lm}, \]  (4b)

\[ f_{S_{lm}} (V_d, V_q) := (f_{P_{lm}} (V_d, V_q))^2 + (f_{Q_{lm}} (V_d, V_q))^2, \]  (4c)

\[ f_{P_{ml}} (V_d, V_q) := \left( V_{d_{ml}}^2 + V_{q_{ml}}^2 \right) g_{ml} \]

\[ - (V_{d_{ml}} V_{d_{rm}} + V_{q_{ml}} V_{q_{rm}}) \left( g_{ml} \cos (\theta_{ml}) + b_{ml} \sin (\theta_{ml}) \right) /\tau_{ml}, \]

\[ + (V_{d_{ml}} V_{q_{rm}} - V_{q_{ml}} V_{d_{rm}}) \left( b_{ml} \cos (\theta_{ml}) - g_{ml} \sin (\theta_{ml}) \right) /\tau_{ml}, \]  (4d)

\[ f_{Q_{ml}} (V_d, V_q) := -\left( V_{d_{ml}}^2 + V_{q_{ml}}^2 \right) b_{ml} /\tau_{ml}^2 \]

\[ + (V_{d_{ml}} V_{d_{rm}} + V_{q_{ml}} V_{q_{rm}}) \left( b_{ml} \cos (\theta_{ml}) - g_{ml} \sin (\theta_{ml}) \right) /\tau_{ml}, \]

\[ + (V_{d_{ml}} V_{q_{rm}} - V_{q_{ml}} V_{d_{rm}}) \left( g_{ml} \cos (\theta_{ml}) + b_{ml} \sin (\theta_{ml}) \right) /\tau_{ml}, \]  (4e)

\[ f_{S_{ml}} (V_d, V_q) := (f_{P_{ml}} (V_d, V_q))^2 + (f_{Q_{ml}} (V_d, V_q))^2. \]  (4f)
The OPF problem is:
\[
\begin{align*}
\min_{V_d, V_q} & \sum_{k \in G} f_{Ck}(V_d, V_q) \quad \text{subject to} \quad (5a)
\end{align*}
\]
\[
\begin{align*}
P_{Gk}^{\min} & \leq f_{Pk}(V_d, V_q) \leq P_{Gk}^{\max} & \forall k \in \mathcal{N} \\
Q_{Gk}^{\min} & \leq f_{Qk}(V_d, V_q) \leq Q_{Gk}^{\max} & \forall k \in \mathcal{N} \\
(V_k^{\min})^2 & \leq f_{Vk}(V_d, V_q) \leq (V_k^{\max})^2 & \forall k \in \mathcal{N} \\
f_{SLm}(V_d, V_q) & \leq (S_{lm}^{\max})^2 & \forall (l, m) \in \mathcal{L} \\
V_{q1} & = 0.
\end{align*}
\]
Constraint (5g) sets the reference bus angle to zero.

III. SEMIDEFINITE RELAXATION OF THE OPF PROBLEM

This section describes a SDP relaxation of the OPF problem adopted from [11], [15], [27]. We use notation from [20], [23] corresponding to the moment relaxations that will be introduced in the following sections. We begin with several definitions. Define the vector of real decision variables \( \hat{x} \in \mathbb{R}^{2n} \) as
\[
\hat{x} := [V_{d1} \ V_{d2} \ \ldots \ V_{qn}]^T
\]
where \((\cdot)^T\) denotes the transpose. A monomial is defined using a vector \( \alpha \in \mathbb{N}^{2n} \) of exponents: \( \hat{x}^\alpha := V_{d1}^{\alpha_1} V_{d2}^{\alpha_2} \ldots V_{qn}^{\alpha_{2n}} \). A polynomial is \( g(\hat{x}) := \sum_{\alpha \in \mathbb{N}^{2n}} g_{\alpha} \hat{x}^\alpha \), where \( g_{\alpha} \) is the real scalar coefficient corresponding to the monomial \( \hat{x}^\alpha \).

Define a linear functional \( L_y \{ g \} \) which replaces the monomials \( \hat{x}^\alpha \) in a polynomial \( g(\hat{x}) \) with real scalar variables \( y \):
\[
L_y \{ g \} := \sum_{\alpha \in \mathbb{N}^{2n}} g_{\alpha} y_{\alpha}.
\]
For a matrix \( g(\hat{x}) \), \( L_y \{ g \} \) is applied componentwise to each element of \( g(\hat{x}) \).

Consider, for example, the vector \( \hat{x} = [V_{d1} \ V_{d2} \ V_{q2}]^T \) corresponding to the voltage components of a two-bus system, where the angle reference (5g) is used to eliminate \( V_{q1} \). Consider also the polynomial \( g(\hat{x}) = (V_{d1}^{2n})^2 - V_{d2}^2 - V_{q2}^2 \). (The constraint \( g(\hat{x}) \geq 0 \) forces the voltage magnitude at bus 2 to be less than or equal to \( V_{d2}^{\max} \).) Then \( L_y \{ g \} = (V_{d1}^2)^2 y_{00} - y_{020} - y_{002} \). Thus, \( L_y \{ g \} \) converts a polynomial \( g(\hat{x}) \) to a linear function of \( y \).

The SDP relaxation of (5) is:
\[
\begin{align*}
\min_{y, \omega_k} & \sum_{k \in G} \omega_k \quad \text{subject to} \quad (8a)
\end{align*}
\]
\[
\begin{align*}
P_{Gk}^{\min} & \leq L_y \{ f_{Pk} \} \leq P_{Gk}^{\max} & \forall k \in \mathcal{N} \\
Q_{Gk}^{\min} & \leq L_y \{ f_{Qk} \} \leq Q_{Gk}^{\max} & \forall k \in \mathcal{N} \\
(V_k^{\min})^2 & \leq L_y \{ f_{Vk} \} \leq (V_k^{\max})^2 & \forall k \in \mathcal{N} \\
(1 - c_{kL}^2) L_y \{ f_{Pk} \} - c_{k0} + \omega_k & \geq \left\| \frac{1}{2 \sqrt{c_{kL}^2}} L_y \{ f_{Pk} \} \right\|_2 & \forall k \in \mathcal{G} \\
& \geq 0 \quad \forall k \in \mathcal{G}
\end{align*}
\]
where \( \omega_k \) are slack variables.

IV. EQUIVALENT FORMULATIONS OF A SMALL EXAMPLE PROBLEM

The SDP relaxation (8) globally solves many OPF problems which do not satisfy any known sufficient conditions guaranteeing exactness [9], [18], indicating the potential for development of broader sufficient conditions. One speculation is that some physical characteristic of the OPF problem predicts the relaxation’s success or failure.

The following example shows that strictly physically based sufficient conditions are unable to definitively predict success or failure of the SDP relaxation for all OPF problems. The
example problem has equivalent two- and three-bus formulations. The relaxation globally solves the two-bus system. For
the three-bus system, however, the relaxation only gives a strict lower bound on the objective value rather than the solution.

A. Example Problem

Consider the two- and three-bus systems in Figs. 2 and 3. For both systems, the voltage magnitudes at buses 1 and 2 are fixed to 1.0 and 1.3 per unit, respectively, and the active power injection at bus 2 is fixed to zero. 3 There are no limits on the reactive power injections at buses 1 and 2. For bus 3 in the three-bus system, the active and reactive power injections are constrained to zero and there is no voltage magnitude constraint. With the active power injections at the other buses fixed to zero, the objective function minimizes active power injection at bus 1.

The resistance-to-reactance ratios for lines in both the two- and three-bus systems are somewhat atypical for transmission systems, but are not particularly unusual for more lossy networks like subtransmission and distribution systems [29]. Similar characteristics to these systems may also occur when using “equivalencing” techniques to reduce larger systems to a smaller representative network [30], [31].

With two quantities specified at each bus k along with two degrees of freedom (Vdk and Vgk), the feasible space for the OPF problem (5) for this example consists of a set of isolated points that are the solutions of the power flow equations. The OPF finds the solution point that has the lowest active power losses. Here, this solution corresponds to the “high-voltage/small angle-difference” power flow solution, which is commonly calculated using a Newton-Raphson iteration initialized from a flat start (i.e., voltages of $1 \angle 0^\circ$) 4. In this paper, however, we use this problem to explore the properties of the convex relaxations.

Since bus 3 in the three-bus system has zero power injections, it can be eliminated by adding $R_{13} + jX_{13}$ and $R_{23} + jX_{23}$ to yield an equivalent two-bus system with two parallel lines. 5 The parallel combination of these lines gives the line impedance $R_{12} + jX_{12}$ shown in the two-bus system of Fig. 2. Thus, the OPF problems for the two- and three-bus systems are equivalent. The voltage at bus 3 in the three-bus system can be directly computed from the solution to the two-bus system. The global solutions are given in Table I.

The SDP relaxation globally solves the two-bus system. However, for the three-bus system, the relaxation only provides a lower bound that is 22% less than the true global optimum (i.e., there exists a large relaxation gap). We note that MATPOWER’s interior point solver [7] fails to converge for the three-bus formulation of this problem but successfully solves the two-bus formulation.

B. Feasible Space Exploration

Although the OPF problems (5) for the two- and three-bus systems share the same feasible spaces, this is not the case for their SDP relaxations (8). This section explores the feasible spaces of these relaxations to illustrate why the SDP relaxation globally solves the two-bus system but fails for the equivalent three-bus system.

Figs. 4 and 5 show projections of the feasible spaces of the two- and three-bus systems, respectively, in terms of the active power injections. The boundary of the oval, shown by the black line in Fig. 4, is the feasible space of the OPF problem (5) for varying values of $P_2$. The region in Fig. 4 consisting of the oval and its interior is the feasible space of the SDP relaxation. For the specified value of $P_2 = 0$, shown by the red dashed line, the OPF problem has a feasible space consisting of the two red squares at the intersection of the red dashed line and the black oval. The SDP relaxation finds the global optimum of (5) (i.e., the leftmost red square) at the orange star.

4 For both two- and three-bus systems, (5) has one other local minimum: there exists one “low-voltage/large angle-difference” power flow solution with larger losses.

5 Elimination of bus 3 requires that the zero power injection at this bus is achieved using an “open circuit to ground”. A “short circuit to ground” could also yield zero power injections. However, a short circuit at bus 3 results in infeasibility of the power flow equations for the loading specified in Fig. 3. Thus, the feasible space of the two-bus system in Fig. 2 can be directly mapped to the feasible space of the three-bus system in Fig. 3.

| Table I | Solutions to Two- and Three-Bus Systems (per unit) |
|---------|---------------------------------------------------|
| Two-Bus System | Three-Bus System |
| $V_{d1} + jV_{q1}$ | $1.000 + j0.000$ | $1.000 + j0.000$ |
| $V_{d2} + jV_{q2}$ | $1.049 - j0.767$ | $1.049 - j0.767$ |
| $V_{d3} + jV_{q3}$ | N/A | $0.849 - j0.586$ |
| $P_1 + jQ_1$ | $5.68 - j7.77$ | $5.68 - j7.77$ |
| $P_2 + jQ_2$ | $0.0 + j12.52$ | $0.0 + j12.52$ |
| $P_3 + jQ_3$ | N/A | $0.0 + j0.0$ |

3 Equality constraints are achieved by setting the upper and lower limits equal (e.g., $V_i^{\text{max}} = V_i^{\text{min}} = 1$ per unit).
Fig. 4. Projection of the Two-Bus System’s Feasible Space. The red squares at the intersection of the black oval and red dashed line are the feasible space for the OPF problem (5). The blue region, including the black oval boundary, is the feasible space for the SDP relaxation (8). The orange star is the solution to the SDP relaxation, which is the global optimum for the two-bus system.

Fig. 5. Projection of the Three-Bus System’s Feasible Space. The feasible space for the OPF problem (5) is denoted by the red squares at the intersection of the red dashed line and the region formed by the black dots. The blue region is the feasible space for the SDP relaxation (8). The orange star is the solution to the SDP relaxation, which does not match the global solution at the leftmost red square.

In Fig. 5a, the black dots outline the feasible space of the OPF problem (5) for varying values of $P_2$ and $P_3$, as determined by repeated homotopy calculations [32]. This feasible space has an ellipsoidal shape with a hole in the interior. The red dashed line corresponds to zero active power injections at buses 2 and 3. The OPF solutions, which are shown by the red squares at the intersection of the exterior of the ellipsoidal shape with the red dashed line, are near the hole in the feasible space. The feasible space of the SDP relaxation, shown by the shaded region, “stretches over” this hole in the OPF’s feasible space. As seen in Fig. 5b, which shows a zoomed view of a cut through $P_3 = 0$, the exterior of the relaxation’s feasible space does not match the feasible space of the OPF problem near this hole. Thus, the solution to the SDP relaxation (8) at the orange star does not match the global solution to the OPF problem (5) at the leftmost red square, and the SDP relaxation is not exact for this formulation. Similar phenomena occur for a range of non-zero active power injections at bus 2.

The hole in the OPF’s feasible space is a non-convexity introduced by “nearby” problems (i.e., different values of $P_3$) in the three-bus system. Without the additional degrees of freedom associated with bus 3, there is no “nearby” non-convexity for the two-bus system. Thus, despite the fact that the OPF problems share the same feasible space (i.e., the red squares in Figs. 4 and 5), the SDP relaxation is exact for the two-bus system but not for the three-bus system.

V. Moment Relaxations

By demonstrating that factors other than just physical characteristics determine success or failure of the SDP relaxation, the example in Section IV motivates the development of tighter convex relaxations that globally solve a broader class of OPF problems. Recognizing that the objective function and all constraints in the OPF problem are polynomial functions of the voltage phasor components enables the application of a hierarchy of convex “moment” relaxations from the Lasserre hierarchy for polynomial optimization problems. The moment relaxations, which converge to the global optimum of (5) with
increasing relaxation order [25], generalize the SDP relaxation presented in Section III. This section introduces and illustrates the moment relaxations using the example from Section IV.

The moment relaxations require definitions beyond those in Section III. Define a vector $x_\gamma$, consisting of all monomials of the voltage components $V_d$ and $V_q$ up to order $\gamma$:

$$
x_\gamma := \begin{bmatrix} 1 & V_{d1} & \ldots & V_{qn} & V_{d1}^2 & V_{d1}V_{d2} & \ldots & V_{d1}V_{q1} & \ldots & V_{q1}^2 & V_{d1}V_{d2} & \ldots & V_{q1}V_{q2} & \ldots & V_{qn}^2 & V_{d1} & \ldots & V_{qn} \end{bmatrix}^T. \tag{10}
$$

The moment relaxations are composed of positive semidefinite constraints on moment and localizing matrices. The symmetric moment matrix $M_\gamma$ is composed of entries $y_{\alpha}$ corresponding to all monomials $\bar{z}^\alpha$ up to order $2\gamma$:

$$
M_{\gamma} \{ y \} := L_y \{ x_\gamma x_\gamma^T \}. \tag{11}
$$

Symmetric localizing matrices are defined for each constraint of (5). For a polynomial constraint $g(x) \geq 0$ of degree $2\eta$, the localizing matrix is:

$$
M_{\gamma-\eta} \{ gy \} := L_y \{ gx_\gamma x_\gamma^T \}. \tag{12}
$$

See (14a), (14b), and (14c) for the vector $x_2$, moment matrix $M_2 \{ y \}$, and the localizing matrix associated with upper voltage magnitude limit $(V_{d1}^2 - V_{d2}^2 - V_{q2}^2 \geq 0$, respectively, for a three-bus OPF problem. Note that the angle reference $V_{q1} = 0$ is used to eliminate $V_{q1}$ in (14). These equations use the notation $L_y(V_{d1}^2, V_{d2}^2, V_{q1}^2, V_{q2}^2) = y_{\alpha\beta\gamma\delta}$. The order-$\gamma$ moment relaxation is:

$$
\begin{align*}
\min_{y_{\omega}, \omega} & \sum_{k \in G} \omega_k \quad \text{subject to} \quad (13a) \\
M_{\gamma-1} \{ (f_{pk} - P_{k}^{\text{min}}) y \} \geq 0 & \quad \forall k \in N \quad (13b) \\
M_{\gamma-1} \{ (P_{k}^{\text{max}} - f_{pk}) y \} \geq 0 & \quad \forall k \in N \quad (13c) \\
M_{\gamma-1} \{ (Q_{k}^{\text{max}} - f_{qk}) y \} \geq 0 & \quad \forall k \in N \quad (13d) \\
M_{\gamma-1} \{ (V_{d1}^2 - V_{d2}^2 - V_{q2}^2) y \} \geq 0 & \quad \forall k \in N \quad (13e) \\
M_{\gamma-1} \{ (V_{d2}^2 - V_{d1}^2) y \} \geq 0 & \quad \forall k \in N \quad (13f) \\
\left(1 - c_{k0} L_y \{ f_{pk} \} - c_{k0} + \omega_k \right) & \geq 0 \quad \forall k \in G \quad (13h) \\
L_y \{ f_{ck} \} = \omega_k & \quad \forall k \in G \quad (13i) \\
M_{\gamma-2} \{ (S_{l}^{\text{max}})^2 - f_{slm} \} \geq 0 & \quad \forall (l, m) \in L \quad (13j) \\
M_{\gamma-2} \{ (S_{l}^{\text{min}})^2 - f_{slm} \} \geq 0 & \quad \forall (l, m) \in L \quad (13k) \\
S_{lm}^{\text{max}} & \geq \left\| \begin{bmatrix} L_y \{ f_{pml} \} \\ L_y \{ f_{qml} \} \end{bmatrix} \right\|_2 \quad \forall (l, m) \in L \quad (13m) \\
S_{lm}^{\text{min}} & \geq \left\| \begin{bmatrix} L_y \{ f_{pml} \} \\ L_y \{ f_{qml} \} \end{bmatrix} \right\|_2 \quad \forall (l, m) \in L \quad (13n) \\
M_{\gamma} \{ y \} & \geq 0 \quad (13o) \\
y_{00, \ldots, 0} & = 1 \quad (13p) \\
y_{\rho s, \ldots, s, \ldots, s} & = 0 \quad \rho = 1, \ldots, 2\gamma. \tag{13p}
\end{align*}
$$

where $\rho$ in the angle reference constraint (13p) is in the index $n + 1$, which corresponds to the variable $V_{q1}$. In the same way as (8), the angle reference can alternatively be used to eliminate all terms corresponding to $V_{q1}$.

As for the SDP relaxation, the globally optimal voltage phasors can be extracted using (9) from a solution to (13) that satisfies the condition $\text{rank}(L_y \{ \bar{x} \bar{x}^T \}) = 1$.

The order $\gamma$ of the moment relaxation (13) must be greater than or equal to half of the degree of any polynomial in the OPF problem (5). This suggests that $\gamma \geq 2$ due to the fourth-order polynomials resulting from the objective function (5a) and the apparent power line flow constraints (5e) and (5f). However, as in the SDP relaxation (8), these can be rewritten using a Schur complement [27] to allow $\gamma \geq 1$. Experience suggests that implementing (5a), (5e), and (5f) both directly and with a Schur complement formulation, as shown in (13h) and (13i) for the quadratic objective function and (13j)–(13m), gives superior results for $\gamma \geq 2$. (Constraints (13i), (13j), and (13k) are not enforced for $\gamma = 1$.)

The second-order relaxation’s moment matrix $M_2 \{ y \}$ is shown in (14b). The upper limit on the voltage magnitude at bus 2 in (13g) corresponds to a positive semidefinite constraint on the localizing matrix shown in (14c).

Fig. 6 shows a projection of the feasible space in terms of active power injections for the second-order moment relaxation of the three-bus system in Section IV. The points in this figure were obtained by gridding the $P_1 - P_2 - P_3$ space, and associating with each grid point a quadratic objective function that achieved its minimum at that point. The relaxation (13) was solved for each of those objective functions while allowing the loading conditions to vary (i.e., the constraints on $P_2$ and $P_3$ were released). The second-order moment relaxation globally solved all these scenarios, with the resulting feasible space in Fig. 6 seemingly equivalent to the space illustrated by the black dots in Fig. 5. Since the power injections result from a non-linear transformation of the voltage components given by the power flow equations (2), the second-order moment relaxation can represent the non-convex space of power injections while maintaining convexity in the decision variables $y_{\alpha}$.

All polynomials in the OPF problem have only even-order monomials (i.e., $\bar{z}^\alpha$ such that $|\alpha|$ is even, where $| \cdot |$ indicates the one-norm). Odd-order terms in the moment relaxations are therefore unnecessary: all $y_{\alpha}$ such that $|\alpha|$ is odd can be set to zero without violating any constraints or changing the objective value. For instance, the positive semidefinite constraint on the second-order relaxation’s moment matrix, $M_2 \{ y \} \succeq 0$, is equivalent to positive semidefinite constraints on two submatrices: the diagonal block corresponding to the degree-two monomials (i.e., $|\alpha| = 2$), which is identified by the green dashed highlighting in (14b), and the terms corresponding to the degree-zero, off-diagonal degree-two, and degree-four monomials (i.e., $|\alpha| = 2k$ for some $k \in \mathbb{N}$), which are identified by the blue dotted highlighting in (14b).

The first-order localizing “matrices” corresponding to the constraints (8b)–(8d) are, in fact, scalars.\footnote{Observe that $L_y \{ g(\bar{x}) x_0 x_0^T \} = L_y \{ g(\bar{x}) \}$ since $x_0 = 1$.} The corresponding scalar constraints in the first-order relaxation (13b)–(13g) are equivalent to the linear constraints in the SDP relaxation (8b)–(8d).
(8d). The moment matrix in the first-order relaxation has all terms \( y_{\alpha} \) such that \( |\alpha| < 2 \) (the diagonal block surrounded by the black line in (14b)), whereas the SDP relaxation has all terms \( y_{\alpha} \) such that \( |\alpha| = 2 \) (the diagonal block with green dashed highlighting in (14b)). The degree-one terms (the terms with orange highlighting in (14b)) have odd \( |\alpha| \) and so are unnecessary, as discussed earlier. Therefore, since \( y_{00...0} \geq 0 \) by (13o), the positive semidefinite constraint on the first-order relaxation’s moment matrix (13h) is equivalent to the positive semidefinite constraint in the SDP relaxation (8h). With an equivalent feasible space and objective function, the SDP relaxation in (8) is the same as the first-order \((\gamma = 1)\) moment relaxation (13).

The moment matrix for the lower-order relaxation \( M_{r-1}(y) \) is contained in the upper-left diagonal block of \( M_{r}(y) \). Likewise, the upper-left diagonal block of the higher-order localizing matrices contain the lower-order localizing matrices. (The first-order matrices are contained within the solid black outlines in the second-order matrices in (14b) and (14c).) Since a necessary condition for a matrix to be positive semidefinite is positive semidefiniteness of all principal submatrices, the moment relaxations form a hierarchy where higher-order constraints imply the lower-order constraints.

Adding a rank-constraint \( \left( L_{y \{x \gamma y \}^T} \right) = 1 \) to the SDP relaxation (8) yields a non-convex problem equivalent to the OPF problem (5). The SDP formulation (8) can thus be understood in terms of a rank relaxation. The higher-order moment relaxations generalize this approach by introducing constraints that are redundant in the OPF problem (5) but strengthen the moment relaxations. Consider \( g(\hat{x}) x_{\alpha} x_{\alpha} \geq 0 \), where \( g(\hat{x}) \geq 0 \) is a generic constraint in the OPF problem (5) with degree \( 2\eta \). The rank-one matrix \( x_{\alpha} x_{\alpha} \) is positive semidefinite by construction, and the scalar constraint \( g(\hat{x}) \) is non-negative. Thus, their product is a rank-one positive semidefinite matrix. Relaxing to \( L_{y \{g(\hat{x}) x_{\alpha} x_{\alpha} \}^T} = 0 \) (i.e., eliminating the rank constraint imposed by \( x_{\alpha} x_{\alpha} \))

\[
x_2 = \begin{bmatrix}
1 & V_{d1} & V_{d2} & V_{d3} & V_{d2} & V_{d3} & V_{d1} & V_{d1} & V_{d3} & V_{d3} & V_{d1} & V_{d1} & V_{d2} & V_{d2} & V_{d2} & V_{d3} & \ldots
\end{bmatrix}^T
\]

(14b)

\[
M_2(y) = L_y \{x_2 x_2^T\} =
\]

\[
M_1 \left\{ \left( V_{2,\text{max}}^2 - fV_{2} \right) y \right\} =
\]

\[
\begin{array}{c}
\text{Note: (5g) is used to remove } V_{q1} \\
\end{array}
\]
Fig. 6. Projection of the Second-Order Moment Relaxation’s Feasible Space for the Three-Bus System. The feasible space for the OPF problem (5) is denoted by the red squares. The second-order moment relaxation gives the global optimum at the orange star. The second-order moment relaxation was exact for all scenarios tested.

Fig. 7. Projection of the Second-Order Mixed SDP/SOCP Relaxation’s Feasible Spaces for the Three-Bus System. The feasible space for the OPF problem (5) is denoted by the red squares. The second-order mixed SDP relaxation gives the global optimum at the orange star. Fig. 7b shows that the second-order mixed SDP/SOCP relaxation is exact for the points near the specified scenario. However, this was not the case for all scenarios: Fig. 7a shows that the second-order mixed SDP/SOCP relaxation includes some points in the “hole” in the feasible space for which \( \text{rank}(L_y \{ \hat{x} \hat{x}^\top \}) > 1 \).

The computational difficulty of solving the moment relaxations grows quickly with the relaxation order due to the size of the positive semidefinite matrix constraints. After elimination of \( V_{q1} \) using the angle reference constraint, the size of the moment matrix (13n) for the order-\( \gamma \) relaxation of a \( n \)-bus system is \( (2n - 1 + \gamma)! / ((2n - 1)!) \gamma! \). For instance, the third-order relaxation of a 10 bus system has a matrix with size \( 1,540 \times 1,540 \). The “dense” formulation of the second-order relaxation is limited to solving problems with less than approximately ten buses [20]–[22]. By exploiting sparsity using techniques analogous to those for the SDP relaxation [33], the second-order relaxation is computationally tractable for systems with up to approximately 40 buses [23]. Extension to larger systems is possible by both exploiting sparsity and only applying the computationally intensive higher-order constraints to specific “problematic” buses [23], [24].

VI. MIXED SDP/SOCP RELAXATION HIERARCHY

The moment relaxations globally solve many OPF problems but are computationally challenging. First proposed in [34], a “mixed SDP/SOCP” hierarchy is tighter than the first-order moment relaxation but more tractable than the higher-order relaxations. This section describes this mixed SDP/SOCP hierarchy in the context of the example problem from Section IV.

The mixed SDP/SOCP hierarchy further relaxes the SDP constraints in the higher-order moment relaxations (13) to less stringent SOCP constraints. To ensure that the mixed SDP/SOCP relaxations are at least as tight as the first-order moment relaxation, positive semidefinite constraints are enforced for the diagonal block of the moment matrix that corresponds to degree-two monomials (i.e., \( y_{\alpha} \) such that
The mixed SDP/SOCP hierarchy enforces the higher-order constraints in the moment and localizing matrices using (15) for (13b)–(13g), (13j)–(13k), and (13n). Since the terms corresponding to odd-order monomials can be set to zero, this reduces to enforcing the SOCP constraints on the submatrices corresponding to those highlighted in blue in (14b) and (14c) for the three-bus system.

Since SOCP constraints have significant computational advantages over SDP constraints, the mixed SDP/SOCP relaxation is more tractable than the formulation of the moment relaxations given in Section V. Further, it is only necessary to enforce the SOCP constraints that correspond to terms in the higher-order matrices that appear in a localizing matrix constraint. This provides additional computational advantages when combined with the approach of selectively applying the higher-order relaxation constraints [23]. See [34] for detailed numerical results demonstrating speed increases between a factor of 1.13 and 18.70 compared to the moment relaxations.

Fig. 7 shows the feasible space of power injections for the second-order mixed SDP/SOCP relaxation. This figure was produced using the same gridding procedure employed in Fig. 6. The relaxation is exact for the specific loading condition $P_2 = P_3 = 0$ considered in Section IV and for nearby loading conditions (see the zoomed-in view of the feasible space shown in Fig. 7b). However, in contrast to the moment relaxations implemented with SDP constraints alone, illustrated in Fig. 6, the mixed SDP/SOCP relaxation was not exact for all scenarios. This is evident by the points that lie in the “hole” in the feasible space (i.e., the points in Fig. 7a that are not in Fig. 6a). As expected, mixed SDP/SOCP relaxations are generally not as tight as the moment relaxations in (13) which use only SDP constraints.

VII. CONCLUSION

An SDP relaxation globally solves many OPF problems which do not satisfy any existing sufficient conditions that assure exactness of the relaxation. This motivates the development of broader sufficient conditions, with a common conjecture being that some physical characteristics of the OPF problem can determine success or failure of the SDP relaxation. This paper has presented a small example OPF problem with two equivalent formulations. The SDP relaxation globally solves only one of the two formulations. This suggests that strictly physically based sufficient conditions for exactness of the SDP relaxation of the OPF problem cannot predict the relaxation’s success or failure for all OPF problems.

The inability to develop universal, physically based sufficient conditions for success of the SDP relaxation motivates researching more sophisticated convex relaxations. We use the small example problem to illustrate two recently developed convex relaxation hierarchies: “moment” relaxations from the Lasserre hierarchy for polynomial optimization and a mixed SDP/SOCP hierarchy derived by relaxing the higher-order constraints in the moment relaxations. Both of these hierarchies generalize the SDP relaxation in order to enable global solution of a broader class of OPF problems.
