We study the behaviour of free energies of baryonic systems composed of three heavy quarks on the lattice in SU(3) pure gauge theory at finite temperature. For all temperatures above $T_c$ we find that the connected part of the singlet (decuplet) free energy of the three quark system is given by the sum of the connected parts of the free energies of $qq$-triplets (-sextets). Using renormalized free energies we can compare free energies in different colour channels as well as those of $qq$- and $qqq$-systems on an unique energy scale.

1. Introduction

While existing studies on static baryonic systems focus on zero temperature simulations\(^1\)^2 or used maximal abelian gauge at finite temperature\(^3\), we have calculated the free energies in different colour channels of heavy three quark systems at finite temperature using Coulomb gauge.

Here we restrict ourselves to the analysis of equilateral triangles above the critical temperature on a $32^3 \times 8$ lattice in SU(3) pure gauge theory. The $qq$-triplet and -sextet free energies have been calculated recently in Ref. 4 and also by us in this work.

2. Colour Channels of the Three Quark System

The state of a three quark system as the product of the irreducible representation of three quarks in colour space can be decomposed into symmetry states

\[
3 \otimes 3 \otimes 3 \cong 1 \oplus 8 \oplus 8' \oplus 10,
\]

where $3$ is the irreducible representation of a quark in colour space and $1$ denotes the singlet, $8$ the first octet, $8'$ the second octet and $10$ the decuplet state. The singlet is totally anti-symmetric, the first octet anti-symmetric in the first and second, the second octet in the second and third component and the decuplet is totally symmetric.
The derivation of the representation of free energies in these colour channels in terms of expectation values of Polyakov loop correlation functions is similar to that for two quark systems\(^5\), but more elaborate. Denoting the Polyakov-loop at \(x_i\) by \(L_i\) and \(\beta = 1/T\), we find

\[
\exp(-\beta F_{1qqq}) = \frac{1}{6} \langle 27 \text{Tr} L_1 \text{Tr} L_2 \text{Tr} L_3 - 9 \text{Tr} L_1 \text{Tr} (L_2 L_3)
- 9 \text{Tr} L_2 \text{Tr} (L_1 L_3) - 9 \text{Tr} L_3 \text{Tr} (L_1 L_2)
+ 3 \text{Tr} (L_1 L_2 L_3) + 3 \text{Tr} (L_1 L_3 L_2) \rangle \quad (2)
\]

\[
\exp(-\beta F^8_{qqq}) = \frac{1}{24} \langle 27 \text{Tr} L_1 \text{Tr} L_2 \text{Tr} L_3 + 9 \text{Tr} L_1 \text{Tr} (L_2 L_3)
- 9 \text{Tr} L_3 \text{Tr} (L_1 L_2) - 3 \text{Tr} (L_1 L_3 L_2) \rangle \quad (3)
\]

\[
\exp(-\beta F^{8'}_{qqq}) = \frac{1}{24} \langle 27 \text{Tr} L_1 \text{Tr} L_2 \text{Tr} L_3 + 9 \text{Tr} L_1 \text{Tr} (L_2 L_3)
- 9 \text{Tr} L_3 \text{Tr} (L_1 L_2) - 3 \text{Tr} (L_1 L_3 L_2) \rangle \quad (4)
\]

\[
\exp(-\beta F^{10}_{qqq}) = \frac{1}{60} \langle 27 \text{Tr} L_1 \text{Tr} L_2 \text{Tr} L_3 + 9 \text{Tr} L_1 \text{Tr} (L_2 L_3)
+ 9 \text{Tr} L_2 \text{Tr} (L_1 L_3) + 9 \text{Tr} L_3 \text{Tr} (L_1 L_2)
+ 3 \text{Tr} (L_1 L_2 L_3) + 3 \text{Tr} (L_1 L_3 L_2) \rangle \quad (5)
\]

With this we obtain for the average free energy of the three quark system \(F_{qqq}^{\text{av}}\) the relation

\[
\exp(-\beta F_{qqq}^{\text{av}}) = \langle \text{Tr} L_1 \text{Tr} L_2 \text{Tr} L_3 \rangle
= \frac{1}{27} \exp(-\beta F_{1qqq}) + \frac{8}{27} \exp(-\beta F^8_{qqq})
+ \frac{8}{27} \exp(-\beta F^{8'}_{qqq}) + \frac{10}{27} \exp(-\beta F^{10}_{qqq}) \quad (6)
\]

For the free energies of the \(qq\)-system we used the operators given in Ref. 5. These operators as well as those defined in (2)-(5) are gauge dependent and thus have to be evaluated in a fixed gauge. We used Coulomb gauge for our calculations.

3. Perturbation Theory and Renormalisation

Table 1 summarizes the Casimirs \(c_s\) found for the free energies in the different colour channels of the quark systems \(q\bar{q}, qq\) and \(qqq\). Using this one obtains the leading order perturbative behaviour of the free energy in the symmetry state \(s\) as well as that of the average free energy for small
distances or high temperatures

\[ \beta F^s(R) = c_s \frac{\alpha \beta}{R} \quad \text{and} \quad \beta F^{\text{av}}(R) = 1 + c_{\text{av}} \frac{\alpha^2 \beta^2}{R^2}, \]

(8)

where \( \alpha = g^2/4\pi \). Here \( R \) is the usual Euclidian distance. For \( qqq \)-systems we restrict ourselves to equilateral triangles. In this case \( R \) denotes the edge length, which is an appropriate distance measure. In the case of the two octet free energies it is convenient to calculate the average of both. For small distances, the average free energies behave like the left most colour channels up to a \( T \)-dependent constant. In the following we will show results for

\begin{table}[h]
\begin{center}
\begin{tabular}{cccccc}
\hline
system & average & singlet & triplet & sextet & octet & decuplet \\
\hline
\( q\bar{q} \) & \(-4/9\) & \(-4/3\) & & & +1/6 & \\
\( qq \) & \(-4/9\) & & \(-2/3\) & +1/3 & & \\
\( qqq \) & \(-4/3\) & \(-2\) & & & \(-1/2^*\) & +1 \\
\hline
\end{tabular}
\end{center}
\caption{Casimirs \( c_s \) and \( c_{\text{av}} \) for the leading order behaviour of \( F^s \) and \( F^{\text{av}} \).}
\end{table}

This simple form only holds for equilateral triangles.

renormalized free energies. These are obtained from renormalized Polyakov loops. The relevant renormalization constants have been determined in Ref. 6 from an analysis of \( q\bar{q} \) free energies and can directly be used also for the \( qqq \)-systems.

4. Colour Channels above \( T_c \) in \( qq \)- and \( qqq \)-systems

We compare the behaviour of the free energy in different colour channels for temperatures \( T/T_c = 3, 6, 9 \) on a \( 32^3 \times 8 \) lattice and for equilateral triangular configurations in Figure 1a-c.

One can see clearly that the singlet free energies are strongly, the octet weaker attractive and the decuplet free energies are repulsive. Together with (7) this results in weakly attractive average free energies. All free energies at a given temperature approach a common \( T \)-dependent constant for large \( R\sqrt{\bar{\sigma}} \).

In Figure 1d we show the connected \( qqq \)-singlet free energies for equilateral triangles

\[ \Delta F^1_{qqq}(R, T) = F^1_{qqq}(R, T) - F^1_{qqq}(\infty, T) \]

and compare it to the corresponding connected \( qq \)-triplet free energies, scaled by a factor of 3. Over the entire \( RT \)-interval we find that \( \Delta F^3_{qqq}(R, T) \) and \( 3\Delta F^3_{qq}(R, T) \) coincide within errors for all temperatures, which suggests
Figure 1. (a)-(c) Free energies of the $qqq$-system in different colour channels for temperatures $T/T_c = 3, 6, 9$. (d) Free Energies of the $qq$-(open symbols) and $qqq$-(full symbols) systems above $T_c$ on a $32^3 \times 8$ lattice. Shown are $\Delta F_{qqq}^1(R, T)$ and $3\Delta F_{qqq}^3(R, T)$ logarithmically.

that above $T_c$ the interactions of the quarks in the $qqq$-singlet state can be decomposed into the pairwise interaction of three $qq$-pairs in a triplet state. The screening masses of both free energy channels are equal within errors. On the other hand we find that $F_{qqq}^1(\infty, T) = \frac{3}{2}F_{qq}^3(\infty, T)$, which shows that at large distances the static quark sources are screened independently by a gluon cloud. We find an analogous relation for the $qqq$-decuplet and $qq$-sextet free energies above $T_c$, the $qqq$-octet free energies show, however, some small deviations.

In Figure 2a we show $F_{qqq}^1(R, T)$ for several temperatures above $T_c$ obtained on a $32^3 \times 8$ lattice renormalized by the procedure mentioned in section 3. For small distances we observe that for all temperatures the $qqq$-singlet free energies coincide, thus becoming $T$-independent.

5. Conclusion and Outlook

We calculated the free energies in different colour channels of heavy three quark systems at finite temperature. While the connected part of the $qqq$-
singlet (-decuplet) free energies are found to be decomposable into three $qq$-triplet (-sextet) free energies for all distances calculated above $T_c$, the asymptotic large distance value of the free energies can be understood in terms of three independently screened quark sources. The $qqq$-octet free energies show deviations.

The approach used here for SU(3) gauge theory can also be applied to full QCD. In Figure 2b we show first results for $F^1_{qqq}(R)$ obtained on a $16^3 \times 4$ lattice in 2-flavour QCD. As in Figure 2a, the $qqq$-singlet becomes $T$-independent for small distances. Like the results in pure gauge simulations, we find that $qqq$-singlet (decuplet) free energies can be decomposed into $qq$-triplet (-sextet) free energies.

In the future we plan to perform a more detailed comparison between $qq$- and $q\bar{q}$-free energies in pure gauge and full QCD. Moreover, we are presently increasing the statistics for three quark free energies below $T_c$ to be able to decide which flux tube geometry is realised close to $T_c$.
