An orthogonal test of the $L$-functions Ratios conjecture

Steven J. Miller

Abstract
We test the predictions of (a weakened version of) the $L$-functions Ratios conjecture for the family of cuspidal newforms of weight $k$ and level $N$, with either $k$ fixed and $N \to \infty$ through the primes or $N = 1$ and $k \to \infty$. We study the main and lower-order terms in the 1-level density. We provide evidence for the Ratios conjecture by computing and confirming its predictions up to a power savings in the family’s cardinality, at least for test functions whose Fourier transforms are supported in $(-2, 2)$. We do this both for the weighted and unweighted 1-level density (where in the weighted case we use the Petersson weights), thus showing that either formulation may be used. These two 1-level densities differ by a term of size $1/\log(k^2N)$. Finally, we show that there is another way of extending the sums arising in the Ratios conjecture, leading to a different answer (although the answer is such a lower-order term that it is hopeless to observe which is correct).

1. Introduction
Zeros of $L$-functions are some of the most important objects in the modern number theory. Numerous problems are connected to them and, frequently, the more detailed information we have about zeros, the more we can say about difficult problems. We remark on just a few of these applications. We then discuss a new procedure to predict these properties, and discuss our tests of its predictions.

The Generalized Riemann hypothesis (GRH) asserts that all non-trivial zeros of an $L$-function have real part $1/2$. Just knowing that there are no zeros on the line $\Re(s) = 1$ for $\zeta(s)$ suffices to prove the Prime number theorem. Similarly the non-vanishing of Dirichlet $L$-functions at $s = 1$ implies the infinitude of primes in arithmetic progression (see, for example, [7]).

Assuming GRH, all the non-trivial zeros lie on the line $\Re(s) = 1/2$. We can thus ask more refined questions about their spacing. The Grand simplicity hypothesis asserts that the imaginary parts of zeros of Dirichlet $L$-functions are linearly independent over $\mathbb{Q}$; this is one of the key inputs in Rubinstein and Sarnak’s [42] analysis of Chebyshev’s bias, the observed preponderance of primes in some arithmetic progressions over others.

Finally, Conrey and Iwaniec [2] showed that if a positive percentage of the spacings between normalized zeros of certain $L$-functions is less than half the average spacing, then the class number of $\mathbb{Q}(\sqrt{-q})$ satisfies $h(q) \gg \sqrt{q} (\log q)^{-A}$ for some $A > 0$.

Since the 1970s, the random matrix theory has provided powerful models to predict the behavior of zeros of $L$-functions. The scaling limits of zeros of individual or of a family of $L$-functions are well-modeled by the scaling limits of eigenvalues of matrices of classical compact groups (see, for example, [6, 17, 24–28, 33, 35, 36]). In particular, these models immediately imply that a positive percentage of zeros is less than half the average spacing apart.

While the corresponding classical compact group is naturally connected to the monodromy group in the function field case, the connection is far more mysterious for number fields. Further,
these models often add the number theoretic pieces in an ad-hoc manner, and thus there is a real need to develop methods that naturally incorporate the arithmetic. (See [9] for some recent results on determining the symmetry group of convolutions of families, and [12] for an alternate approach which is a hybrid of the Euler product and the Hadamard expansion, which has the advantage of the arithmetic arising naturally).

In this work we concentrate on one such approach, the $L$-functions Ratios conjecture of Conrey, Farmer and Zirnbauer [4, 5], which provides a recipe for predicting many properties of $L$-functions to a phenomenal degree, ranging from $n$-level correlations and densities to moments and mollifiers (see [3] for numerous applications). In our analysis below we actually use a weaker version of the Ratios conjecture recipe than is stated in [5], as we do not need one of their assumptions in our analysis; we comment on this in greater detail in Remark 1.8.

In [31] we showed that the Ratios conjecture successfully predicts all lower-order terms up to size $O(N^{-1/2+\epsilon})$ in the 1-level density for certain families of quadratic Dirichlet characters, at least provided that the Fourier transform of the test function is supported in $(-1/3, 1/3)$. In this paper we apply the Ratios conjecture to families of cuspidal newforms. We chose these families as the 1-level density can be determined for test functions whose Fourier transform is supported in $(-2, 2)$. (If we assume Hypothesis S from [23], we can extend the number theory calculations up to $(-22/9, 22/9)$; see (4.35).) To prove results for support exceeding $(-1, 1)$ requires us to take into account non-diagonal terms, specifically sums of Bessel functions and Kloosterman sums. Thus our hope is that this will be a very good test of the Ratios conjecture.

1.1. Notation

We first set some notation. Let $f \in S_k(N)$, the space of cusp forms of weight $k$ and level $N$, let $B_k(N)$ be an orthogonal basis of $S_k(N)$ and let $H^*_k(N)$ be the subset of newforms. To each $f$ we associate an $L$-function

$$L(s, f) = \sum_{n=1}^{\infty} \lambda_f(n)n^{-s}. \quad (1.1)$$

The completed $L$-function is

$$\Lambda(s, f) = \left(\frac{\sqrt{N}}{2\pi}\right)^s \Gamma\left(s + \frac{k - 1}{2}\right) L(s, f), \quad (1.2)$$

and satisfies the functional equation $\Lambda(s, f) = \epsilon_f \Lambda(1 - s, f)$ with $\epsilon_f = \pm 1$. Thus $H^*_k(N)$ splits into two disjoint subsets:

$$H^+_k(N) = \{f \in H^*_k(N) : \epsilon_f = +1\} \quad \text{and} \quad H^-_k(N) = \{f \in H^*_k(N) : \epsilon_f = -1\}.$$

We often assume the GRH, namely that all non-trivial zeros of $L(s, f)$ have real part $1/2$.

From [23, Equation (2.73)] we have for $N > 1$ that

$$|H^+_k(N)| = \frac{k - 1}{24} N + O\left((kN)^{5/6}\right). \quad (1.3)$$

If $N = 1$ then $H^+_k(1) = H^*_k(1)$ if $k \equiv 0 \mod 4$ and $H^-_k(1) = H^*_k(N)$ if $k \equiv 2 \mod 4$, where $|H^*_k(1)| = (k - 1)/12 + O(k^{2/3})$.

We let $D_{1, H^*_k(N); R}(\phi)$ denote the weighted 1-level density for the family $H^*_k(N)$:

$$D_{1, H^*_k(N); R}(\phi) = \sum_{f \in H^*_k(N)} \omega_f^*(N) \sum_{\gamma_f \neq L(1/2+i\gamma_f, f) = 0} \phi\left(\frac{\gamma_f \log R}{2\pi}\right). \quad (1.4)$$
We discuss the weights $\omega_f^*(N)$ in greater detail in §1.2, and $R = k^2N$ is (essentially\textsuperscript{†}) the analytic conductor, which is constant throughout the family. (It greatly simplifies our analysis to have a family where the analytic conductors are constant. This allows us to pass the summation over the family past the test function to the Fourier transforms. Non-constant families can often be handled, at a cost of additional work and sieving (see, for example, [29]).) Katz and Sarnak [24, 25] conjectured that as the conductors tend to infinity, the 1-level density agrees with the scaling limit of a classical compact group. There are now many cases where, for suitably restricted test functions, we can show agreement between the main terms and the conjectures; see, for example, [8, 10, 11, 14, 19, 20, 23, 24, 29, 37, 38, 40, 41, 45]. Now that the main terms have been successfully matched in numerous cases, it is natural to try to analyse the lower-order terms. Here we break universality. While the arithmetic of the family does not enter into the main terms, it does surface in the lower-order term (see, for example, [10, 30–32, 39, 44]).

The Ratios conjecture is a recipe for predicting the main and lower-order terms (often up to square-root in the family’s cardinality) for ratios of $L$-functions. Consider a family $F$ of $L$-functions with some weights $\omega_f$. We shall be particularly interested in both

$$R_F(\alpha, \gamma) = \sum_{f \in F} \omega_f \frac{L(1/2 + \alpha, f)}{L(1/2 + \gamma, f)}$$

and $\partial R_F(\alpha, \gamma)/\partial \alpha \bigg|_{\alpha=\gamma=s}$. We are interested in the derivative as a contour integral of it yields the 1-level density.

1.2. Weights

To simplify some of the arguments, we content ourselves with investigating two cases: $k$ is fixed and $N \to \infty$ through the primes (With additional work, the arguments should generalize to $N$ square-free, though with worse error terms), and $N = 1$ and $k \to \infty$. Throughout our analysis we shall need to investigate sums such as

$$\sum_{f \in H_k^*(N)} \lambda_f(m)\lambda_f(n).$$

It is technically easier to consider weighted sums

$$\sum_{f \in H_k^*(N)} \omega_f(N)\lambda_f(m)\lambda_f(n),$$

where the $\omega_f(N)$ are the harmonic (or Petersson) weights, though for completeness we study the unweighted sums as well. These are defined by

$$\omega_f^*(N) = \frac{\Gamma(k-1)}{(4\pi)^{k-1}(f,f)_N},$$

where

$$(f,f)_N = \int_{\Gamma_0(N)\backslash \mathbb{H}} f(z)\overline{f}(z) y^{k-2} \, dx \, dy.$$  

These weights are almost constant. We have the bounds (see [18, 22])

$$N^{-1-\epsilon} \ll_k \omega_f^*(N) \ll_k N^{-1+\epsilon};$$

\textsuperscript{†}Sometimes the analytic conductor is defined slightly differently, incorporating some of the constants in the Gamma factors. In investigations of the 1-level density for these families, however, these factors are independent of $k$ and $N$, and for our purposes all that matters is the $k$ and $N$ dependence in the conductor. Thus there is no loss in setting $R = k^2N.$
if we allow ineffective constants we can replace \(N^\epsilon\) with \(\log N\) for \(N\) large.

The main tool for evaluating these (weighted) sums is the Petersson formula; we state several useful variants in Appendix A.

If \(N > 1\) we should use modified weights \(\omega_f(N)/\omega(N)\), where

\[
\omega(N) = \sum_{f \in H_k^* (N)} \omega_f(N).
\]

The reason is that our family does not include the oldforms. One advantage of restricting to \(N\) prime is that the only oldforms in \(S_k (N)\) are forms of level 1. We know that there are only \(O(k)\) such forms. As each \(\omega_f(N) \ll N^{-1+\epsilon}\),

\[
\sum_{f \in H_k^* (N)} \omega_f(N) = \sum_{f \in S_k (N)} \omega_f(N) + O \left( \frac{k}{N^{1-\epsilon}} \right) = 1 + O \left( \frac{k}{N^{1-\epsilon}} \right).
\]

Thus for \(k\) fixed and \(N \to \infty\), the difference between using \(\omega_f(N)\) and \(\omega_f(N)/\omega(N)\) is \(O(N^{-1+\epsilon})\). We set

\[
\omega^*_f(N) = \begin{cases} 
\omega_f(1) & \text{if } N = 1, \\
\omega_f(N)/\omega(N) & \text{if } N > 1;
\end{cases}
\]

note that

\[
\sum_{f \in H_k^* (N)} \omega^*_f(N) = 1 = (1 + O (N^{-1+\epsilon})) \sum_{f \in B_k (N)} \omega_f(N).
\]

Remark 1.1. For some problems, such as bounding the order of vanishing at the central point for families of cuspidal newforms [19, 23], it is desirable to study the unweighted family. We shall see below that there is a difference of size \(1/\log R\) between the weighted and unweighted 1-level densities. The predictions from the Ratios conjecture (for weighted and unweighted families) agree with the corresponding result from the number theory in both cases.

1.3. Main results

Theorem 1.2. Assume GRH for \(\zeta(s)\) and all \(L(s, f)\) with \(f \in H_k^* (N)\). The (weakened version of the) Ratios conjecture predicts

\[
D_{1,H_k^*(N):R} (\phi) = 2 \sum_p \hat{\phi} \left( \frac{2 \log p}{\log R} \right) \frac{\log p}{p \log R} + M(\phi) \\
+ \frac{1}{\log R} \int_{-\infty}^{\infty} \left( 2 \log \frac{\sqrt{N}}{\pi} + \psi \left( \frac{1}{4} + \frac{k \pm 1}{4} + \frac{2\pi it}{\log R} \right) \right) \phi(t) \, dt \\
+ O \left( (kN)^{-1/2+\epsilon} \right),
\]

where\(^4\)

\[
M(\phi) = \frac{2i^k \mu(N)}{N \log R} \int_{-\infty}^{\infty} X_L \left( \frac{1}{2} + \frac{2\pi it}{\log R} \right) \zeta(2) \left( \frac{\zeta(2)}{(2 + (8\pi it/\log R))} \right) \zeta \left( 1 + \frac{4\pi it}{\log R} \right) \\
\cdot \prod_{p} \left( 1 - \frac{p^{4\pi it/\log R} - 1}{p(p^{1+4\pi it/\log R} + 1)} \right) e^{-2\pi it(\log N/\log R)} \phi(t) \, dt
\]

\(^4\)If \(N = 1\), note that the factor \((\mu(N)/N) \exp (-2\pi it \log N/\log R)\) below equals 1.
and \( X_L(s) \) is as in (2.9). If \( N > 1 \) then \( M(\phi) \ll N^{-1} \). Let \( \text{supp}(\hat{\phi}) \subset (-\sigma, \sigma) \). If \( N = 1 \) then 
\[
M(\phi) \ll 200^k k^{-(1-4\sigma)/3}k,
\]
which decays more rapidly than \( k^{-\delta} \) for any \( \delta > 0 \) provided that \( \sigma < 1/4 \).

**Remark 1.3.** Our estimate for \( M(\phi) \) is significantly worse when \( N = 1 \); see Remark 3.5 for an explanation and a connection to other problems. Interestingly, if we change the order of some of the steps in the Ratios conjecture’s recipe, then \( M(\phi) \) changes by a factor of \( e^{-7} \). See Appendix C for complete details, as well as Remark 2.10.

The 1-level density computation has some differences depending on whether or not \( N \to \infty \) through the primes or \( N = 1 \) and \( k \to \infty \). We therefore separate our results into two cases; see Remark 1.8 for an explanation of these differences. Further, we can often obtain results for smaller support without assuming GRH for Dirichlet \( L \)-functions, and thus we isolate these as well.

**Theorem 1.4.** Let \( \text{supp}(\hat{\phi}) \subset (-\sigma, \sigma) \) and let \( N \to \infty \) through the primes.

- **Density theorem limited:** If \( \sigma < 3/2 \) then the weighted 1-level density for the family \( H_k^*((N) \) agrees with the prediction from the Ratios conjecture up to errors of size \( O(N^{\sigma-(3/2)+\epsilon} + N^{\sigma/2-1+\epsilon'} + N^{(\sigma/4)-1+\epsilon''}) \).

- **Density theorem extended:** Assuming GRH for \( \zeta(s) \), all Dirichlet \( L \)-functions and \( L(s, f) \), the weighted 1-level density agrees with the prediction from the Ratios conjecture up to errors of size \( O(N^{\sigma/2-1+\epsilon} + N^{(\sigma/4)-1+\epsilon''}) \).

**Remark 1.5.** Theorem 1.4 implies that we have agreement up to a power savings in \( N \) for \( \sigma < 3/2 \), and up to square-root cancelation for \( \sigma < 1 \). Assuming GRH, we can extend agreement up to \( \sigma < 2 \), again saving a power in \( N \).

**Theorem 1.6.** Let \( \text{supp}(\hat{\phi}) \subset (-\sigma, \sigma) \) \( N = 1 \) and \( k, K \to \infty \).

- **Density theorem limited:** The weighted 1-level density for the family \( H_k^*((1) \) agrees with the prediction from the Ratios conjecture up to errors of size \( O(k^{-(5-3\sigma)/6+\epsilon}) \) for \( \sigma < 1/4 \). If we knew \( M(\phi) \ll k^{-(5-3\sigma)/6+\epsilon} \) for \( \sigma < 1 \), then we would have agreement up to \( \sigma < 1 \).

- **Density theorem extended:** Let \( h \) be a Schwartz function compactly supported on \((0, \infty)\). Consider a weighted average (over \( k \)) of the weighted 1-level density

\[
A^*(K; \phi) = \frac{1}{A^*(K)} \sum_{k \equiv 0 \mod 2} 24 \frac{k-1}{k} h \left( \frac{k-1}{K} \right) \sum_{f \in H_k^*((1)} D_{1,H_k^*((1),k^2} \left( \phi, \right),
\]

where

\[
A^*(K) = \sum_{k \equiv 0 \mod 2} 24 \frac{k-1}{k} h \left( \frac{k-1}{K} \right) |H_k^*((1)| = \hat{h}(0)K + O(K^{2/3}).
\]

Assuming GRH for \( \zeta(s) \), all Dirichlet \( L \)-functions and \( L(s, f) \), the 1-level density agrees with the prediction from the Ratios conjecture up to errors of size \( O(K^{-(5-\sigma)/6+\epsilon} + K^{\sigma-2+\epsilon}) \) for \( \sigma < 1/4 \). If we knew \( M(\phi) \ll K^{-(5-\sigma)/6+\epsilon} + K^{\sigma-2+\epsilon} \) for \( \sigma < 2 \), then we would have agreement up to \( \sigma < 2 \).

- **Hypothesis S and Density theorem extended:** Assume Hypothesis S from [23] (equation that is, (4.35)) with \( A = 0 \) and \( \alpha = 1/2 \). Then as \( K \to \infty \) the weighted average (over \( k \)) of the weighted 1-level density agrees with the prediction from the Ratios conjecture for \( \sigma < 1/4 \).
If we knew $M(\phi) \ll K^{-2(2.5-\sigma)} + K^{-(5-\sigma)/6+\epsilon} + K^{-11/2(1-9/22\sigma)}$ for $\sigma < 22/9$, then we would have agreement up to $\sigma < 22/9$.

**Remark 1.7.** Theorem 1.6 implies that we have agreement up to a power savings in $K$ for $\sigma < 1/4$; in fact, we agree beyond square-root cancelation in this range. Assuming GRH, by averaging over $k$ we can extend our calculations up to $\sigma < 2$ (or, if we assume Hypothesis S, up to $\sigma < 22/9$). If we knew that $M(\phi)$ were small, we would again save a power in $N$ (with agreement up to square-root cancelation for $\sigma < 3/2$ if we assume GRH for Dirichlet $L$-functions, or up to $\sigma < 22/9$ if we assume Hypothesis S).

**Remark 1.8.** We briefly comment on the differences in the calculations for $N \to \infty$ through the primes and $N = 1$ and $k \to \infty$. In the first family, the sign of the functional equation is basically 1 half the time and $-1$ the other half, while in the second family it is either always 1 (if $k \equiv 0 \mod 4$) or $-1$ (if $k \equiv 2 \mod 4$). It is natural to argue in constructing the Ratios conjecture recipe similarly as in other conjectures, such as in the Moments conjecture (see [6]). In both, any product of the signs of the functional equations is replaced with the average of the signs of the functional equations in the family. (See, for instance, the comments after equation (4.1.5) and the analysis after equation (4.5.4) in [6] or the comments after (5.5) in [5]; note that in an earlier draft of [5] there was no mention of replacing products of epsilon factors with their averages, though this is a natural thing to do.) When $N \to \infty$ we thus do not expect any term, as the average of the functional equations is zero; however, for $N = 1$ the average is non-zero (either 1 or $-1$), and there will be a predicted term (which may or may not be small, but which must be analyzed). This is one reason why our results are significantly weaker when $N = 1$. (Another is that the analytic conductor is $k^2N$. If $N = 1$ then the conductor is essentially the square of the family’s cardinality, while if $N \to \infty$ the conductor is of the same size as the family’s cardinality.) If we were to follow the Ratios conjecture recipe completely, we would not have the $M(\phi)$ term when $N \to \infty$. We choose to include $M(\phi)$ as our analysis that it is $O(1/N)$ provides support for replacing the epsilon factors in the Ratios conjecture recipe with their average over the family (in this case, zero).

**Theorem 1.9.** Assume GRH for $\zeta(s)$, all Dirichlet $L$-functions and all $L(s, f)$. The unweighted 1-level density for $H^*_N(N)$ agrees with the predictions of the Ratios conjecture for the unweighted family, up to a power savings in the family’s cardinality, as $N \to \infty$ through the primes; this answer differs from the weighted 1-level density by an additional term of size $1/\log R$. The Ratios conjecture applied to the unweighted family predicts that

$$
D^\text{unwt}_{1,H^*_N(N);R}(\phi) = \frac{1}{\log R} \int_{-\infty}^{\infty} \left( 2 \log \frac{\sqrt{N}}{\pi} + \psi \left( \frac{1}{4} + \frac{1}{4} + \frac{2\pi i t}{\log R} \right) \right) \phi(t) \, dt \\
+ 2 \sum_{\nu \equiv 0 \mod 2, p \not\equiv N} \sum_{p' \geq 2} \frac{p-1}{p'} \phi \left( \nu \log \frac{p}{\log R} \right) \frac{\log p}{\log R} \\
+ O \left( (kN)^{-1/2+\epsilon} \right),
$$

which agrees with the number theory up to errors of size $O(N^{-2-\sigma}/6+\epsilon)$.

**Remark 1.10.** Theorem 1.9 and our other results imply that the predictions from the $L$-functions Ratios conjecture agree with the number theory for both the weighted and unweighted families. Thus, when investigating cuspidal newforms, we may study either family.
The paper is organized as follows. In §2 we describe the Ratios conjecture’s recipe, and determine its prediction for the 1-level density for our families. In §3 we analyze these predictions and prove Theorem 1.2. In §4 we prove Theorems 1.4 and 1.6, which show that the 1-level densities agree (up to a power savings in the cardinality of the families, at least for suitably restricted test functions) with what can be proved. Finally, in §5 we analyze the unweighted 1-level density, and prove Theorem 1.9.

2. Ratios conjecture

The Ratios conjecture is a recipe to predict the main and lower-order terms for a variety of problems. We analyze its predictions for the 1-level density for families of cuspidal newforms. We first briefly describe its recipe for predicting quantities related to

\[ R_F(\alpha, \gamma) = \sum_{f \in F} \omega_f \frac{L(1/2 + \alpha, f)}{L(1/2 + \gamma, \overline{f})}. \] (2.1)

In the description below, we actually use a slightly weakened version of the Ratios conjecture; the difference is in step (3).

1. Use the approximate functional equation to expand the numerator into two sums plus a remainder. The first sum is over \( m \) up to \( x \) and the second over \( n \) up to \( y \), where \( xy \) is of the same size as the analytic conductor (typically one takes \( x = y \)). We ignore the remainder term.

2. Expand the denominator by using the generalized Mobius function

\[ \frac{1}{L(s, f)} = \sum_{h} \frac{\mu_f(h)}{h^s}, \]

where \( \mu_f(h) \) is the multiplicative function equaling 1 for \( h = 1 \), equaling \( -\lambda_f(p) \) if \( h = p \), and \( \chi_0(p) \) if \( h = p^2 \) (with \( \chi_0 \) the trivial character modulo \( N \)) and 0 otherwise.

3. Execute the sum over \( F \), keeping only main (diagonal) terms. In [5] there is an additional step before executing the sums over \( m \) and \( n \), as they replace any product over epsilon factors (arising from the signs of the functional equations) with the average value of the sign of the functional equation in the family. For families of constant sign (such as \( N = 1 \)), there is no difference; however, for families where the sign varies (such as \( N \to \infty \)) there is a significant difference, as they would not have our term \( M(\phi) \). We are thus using a weaker recipe of the Ratios conjecture; we choose to include the analysis of the contribution from the signs of the functional equation as this provides support for the claim that we may ignore any term multiplied by signs of functional equations which average to zero. (Also, of course, \( M(\phi) \) is present when \( N = 1 \).) See Remark 1.8 for additional details.

4. Extend the \( m \) and \( n \) sums to infinity (that is, complete the products).

5. Differentiate with respect to the parameters, and note that the size of the error term does not significantly change upon differentiating.

6. A contour integral involving \( \frac{\partial}{\partial \alpha} R_F(\alpha, \gamma) \big|_{\alpha = \gamma = s} \) yields the 1-level density.

We now describe these steps in greater detail and deduce the Ratios conjecture’s prediction for the 1-level density.

Remark 2.1. It is almost miraculous how well the Ratios conjecture works, given that several of the steps involve throwing away significant error terms. The miracle is that all these errors seem to cancel, and the resulting expression is correct to a remarkable order. See Remark 2.11 for more details.
Remark 2.2. Differentiating is essentially harmless because we have analytic functions. If the error were $N^{-1/2} \cos(N^2 \alpha)$ and $\alpha$ was forced to be real, then differentiating increases the error from size $N^{-1/2}$ to $N^{3/2}$! For us, $\alpha$ will be complex. By Cauchy’s integral theorem, if $f$ is analytic at $z_0$ then

$$f'(z_0) = \frac{1}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^2} \, dz,$$

(2.2)

where $C$ is a circle of very small radius of about $z_0$. The sum of the ratios is analytic, and we shall see later that the main term is analytic. Thus their difference, the error term, is also analytic. Applying Cauchy’s argument with a circle of very small radius, say $\log^{-2009} R$, we see that the effect of differentiating is only to increase the error by some powers of $\log R$. We thank David Farmer for pointing this out to us.

2.1. Approximate functional equation

We state the approximate functional equation in greater generality than we need, though not the greatest generality possible; see [6, Section 1] for more details. Let

$$L(s) = \sum_{n=1}^{\infty} \frac{a_n}{n^s}$$

(2.3)

be a nice $L$-function with real coefficients ($a_n \in \mathbb{R}$),

$$\gamma_L(s) = P(s)Q^s \prod_{j=1}^{w} \Gamma(w_j s + \mu_j)$$

(2.4)

with $Q, w_j > 0$, $\mu_j \geq 0$ and $P(s)$ a real polynomial whose zeros in $\Re(s) > 0$ are at the poles of $L(s)$ (so if $L(s)$ has no poles then $P(s)$ is constant). Let

$$\xi_L(s) = \gamma_L(s) L(s) = \epsilon \xi_L(1 - s)$$

(2.5)

be the completed $L$-function, with $|\epsilon| = 1$ the sign of the functional equation and $\overline{\xi_L(s)} = \xi_L(\overline{s})$. Our assumptions imply that $\overline{\xi_L(s)} = \xi_L(s)$. Set

$$X_L(s) = \frac{\gamma_L(1 - s)}{\gamma_L(s)} = \frac{P(1 - s)Q^{1-s} \prod_{j=1}^{w} \Gamma(w_j(1-s) + \mu_j)}{P(s)Q^s \prod_{j=1}^{w} \Gamma(w_j s + \mu_j)}.$$

(2.6)

Then we have the following result.

Lemma 2.3 (The Approximate Functional Equation). Notation and assumptions as above,

$$L(s) = \sum_{m \leq x} \frac{a_m}{m^s} + \epsilon X_L(s) \sum_{n \leq y} \frac{a_n}{n^{1-s}} + \text{remainder},$$

(2.7)

where $xy$ is of the same size as the analytic conductor.

Remark 2.4. The Ratios conjecture’s recipe for generating predictions ignores the remainder term in the approximate functional equation. Thus we too shall ignore these errors in our arguments below, and treat the approximate functional equation as exact.
For us, \( L(s) \) will be a weight \( k \) cuspidal newform of level \( N \), which we shall denote by \( L(s, f) \). In this case, we have (see \([23]\), for instance) that

\[
\gamma_L(s) = \left( \frac{2k}{8\pi} \right)^{1/2} \left( \frac{\sqrt{N}}{\pi} \right)^s \Gamma\left( \frac{s}{2} + \frac{k-1}{4} \right) \Gamma\left( \frac{s}{2} + \frac{k+1}{4} \right) = \left( \frac{\sqrt{N}}{2\pi} \right)^s \Gamma\left( s + \frac{k-1}{2} \right) ;
\]

note that \( \gamma_L(s) \) depends only on the weight \( k \) and the level \( N \) of the cuspidal newform \( f \). This yields the following expressions for \( X_L(s) \):

\[
X_L(s) = \left( \frac{\sqrt{N}}{\pi} \right)^{1-2s} \frac{\Gamma\left( (1-s)/2 + (k-1)/4 \right) \Gamma\left( (1-s)/2 + (k+1)/4 \right)}{\Gamma\left( s/2 + (k-1)/4 \right) \Gamma\left( s/2 + (k+1)/4 \right)} = \left( \frac{\sqrt{N}}{2\pi} \right)^{1-2s} \frac{\Gamma\left( (1-s)/2 + (k-1)/2 \right)}{\Gamma\left( s/2 + (k-1)/2 \right)}. \tag{2.8}
\]

Finally, the analytic conductor of a cuspidal newform of weight \( k \) and level \( N \) is (up to a constant) \( k^2 N \). Thus we will typically take \( x = y \sim \sqrt{k^2 N} \) in the approximate functional equation.

2.2. Ratios conjecture

Let \( \chi_0 \) denote the principal character with conductor \( N \). For \( f \) a weight \( k \) cuspidal newform of level \( N \) we have

\[
L(s, f) = \prod_p \left( 1 - \frac{\lambda_f(p)}{p^s} + \frac{\chi_0(p)}{p^{2s}} \right)^{-1} = \sum_{n=1}^{\infty} \frac{\lambda_f(n)}{n^s},
\]

\[
\frac{1}{L(s, f)} = \prod_p \left( 1 - \frac{\lambda_f(p)}{p^s} + \frac{\chi_0(p)}{p^{2s}} \right) = \sum_{n=1}^{\infty} \frac{\mu_f(n)}{n^s}, \tag{2.10}
\]

where \( \mu_f(n) \) is the multiplicative function such that \( \mu_f(1) = 1, \mu_f(p) = -\lambda_f(p), \mu_f(p^2) = \chi_0(p) \) and \( \mu_f(p^k) = 0 \) for \( k \geq 3 \).

Let \( \mathcal{F} \) be a family of weight \( k \) cuspidal newforms of level \( N \). The Ratios conjecture for the family gives an expansion for

\[
R_{\mathcal{F}}(\alpha, \gamma) = \sum_{f \in \mathcal{F}} \omega_f \frac{L((1/2) + \alpha, f)}{L((1/2) + \gamma, f)}, \tag{2.11}
\]

where \( \alpha \) and \( \gamma \) satisfy

(1) \( \Re(\alpha) \in (-1/4, 1/4) \);

(2) \( \Re(\gamma) \in (1/ \log |\mathcal{F}|, 1/4) \);

(3) \( \Im(\alpha), \Im(\gamma) \ll_\epsilon |\mathcal{F}|^{1-\epsilon} \) for all \( \epsilon > 0 \).

We have introduced weights \( \omega_f \), as often in practice the weighted sum is significantly easier to control. For example, we may take \( \omega_f \) to be the Petersson weights, which facilitates applying the Petersson formula (see Appendix A for statements). As remarked in §1.2, it is convenient to choose \( \omega_f = \omega_f^*(N) \) (see (1.13)).

We shall concentrate on the diagonal terms in the Petersson formula. Thus if our family is \( \mathcal{H}_k^*(N) \), then by the Petersson formula we have for \( n_1 \) and \( n_2 \) relatively prime to \( N \),

\[
\sum_{f \in \mathcal{H}_k^*(N)} \omega_f^*(N)\lambda_f(n_1)\lambda_f(n_2) = \delta_{n_1, n_2} + \text{small}. \tag{2.12}
\]
The weights are normalized to sum to 1. If \( N > 1 \) our sums do not include the oldforms; however, the oldforms do not contribute to the main term of the Petersson formula in this case.

In general, we must be careful by what we mean by ‘small’ when we apply the Petersson formula. The error term is a Bessel–Kloosterman sum, and is typically small only if \( n_1 \) and \( n_2 \) are not too large with respect to \( k \) and \( N \) (and are relatively prime to \( N \)). It is very important that our sums are restricted. It is only after we compute the main term that the heuristics of the Ratios conjecture tells us to extend the sums to infinity. Depending on how (and when!) we extend our sums to infinity can lead to different answers. (These differences, however, involve terms of size \( 1/N \), which is unimaginable beyond anything we can hope to prove (except possibly if \( N = 1 \); we hope to return to this in a future paper). Interestingly, however, the difference between these two terms is related to sieving actual versus random primes. See Appendix C.)

Unless our family is all of \( H(f)(N) \) and \( N = 1 \), however, the sign of the functional equation is not constant. (See Remark 1.8 for comments on how the non-constancy of the signs of the functional equation affects the Ratios conjecture’s prediction.) For square-free \( N \) we have

\[
\epsilon_f = i^k \mu(N) \lambda_f(N) \sqrt{N};
\]

thus the sign of the functional equation only weakly depends on the specific form \( f \). Further \( \lambda_f(q)^2 = 1/q \) if \( q \mid N \). Note \( \mu(1) = 1 \) and \( \mu(N) = -1 \) if \( N \) is prime, and since \( k \) is even we have \( i^k = \pm 1 \). Thus there is at most one ‘bad’ prime, namely \( N \).

**Remark 2.5.** We consider just the case \( \mathcal{F} = H(f)(N) \) with \( N \) either 1 or prime here; more involved arguments should be able to handle the case of \( N \) square-free (at the cost of worse error terms), and we will investigate the sub-families \( H(f)(N) \) in a future paper [21].

**Lemma 2.6.** The Ratios conjecture predicts that

\[
R_{H(f)(N)}(\alpha, \gamma) = \prod_p \left( 1 - \frac{1}{p^{1+\alpha+\gamma}} + \frac{1}{p^{1+2\gamma}} \right) - i^k \mu(N) \lambda_f(N) \sqrt{N} \left( \frac{1}{2} + \alpha \right) \frac{\lambda_f(N)}{N^{1/2+\gamma}} \prod_p \left( 1 + \frac{p^{1-\alpha+\gamma}}{p^{1+2\gamma}(p^{1-\alpha+\gamma} - 1)} \right) + O \left( \frac{1}{|H(f)(N)|^{-1/2+\epsilon}} \right),
\]

where the \( N \)-factors are present only if \( N \) is prime.

**Proof.** From the Approximate functional equation (Lemma 2.3) and (2.13) we have

\[
L \left( \frac{1}{2} + \alpha, f \right) = \sum_{m \leq x} \frac{\lambda_f(m)}{m^{(1/2)+\alpha}} + i^k \mu(N) \lambda_f(N) \sqrt{N} X_L \left( \frac{1}{2} + \alpha \right) \sum_{n \leq y} \frac{\lambda_f(n)}{n^{(1/2)-\alpha}},
\]

where \( x = y \sim k^2 N \). From (2.10) we have

\[
\frac{1}{L(1/2 + \gamma, f)} = \sum_{h=1}^{\infty} \frac{\mu_f(h)}{h^{1/2+\gamma}}.
\]
Therefore

\[
R_{\mathcal{H}^*_{x}}(\alpha, \gamma) = \sum_{f \in H^*_{x}} \omega_f^*(N) \left[ \sum_{m \leq x} \frac{\mu_f(h)\lambda_f(m)}{h^{(1/2)+\gamma}m^{(1/2)+\alpha}} + i^k \mu(N)X_0 \left( \frac{1}{2} + \alpha \right) \sqrt{N} \sum_{n \leq y} \frac{\mu_f(h)\lambda_f(N)\lambda_f(n)}{h^{(1/2)+\gamma}m^{(1/2)-\alpha}} \right]. \tag{2.17}
\]

If \(N > 1\) then the presence of the \(\lambda_f(N)\) factor requires us to handle the two sums in a slightly different manner. We first analyze the sum without the \(\lambda_f(N)\) factor. By the Petersson formula, we have \(\sum_{f \in H^*_{x}} \omega_f^*(N)\lambda_f(n_1)\lambda_f(n_2) = \delta_{n_1,n_2} + \text{small} \) if at least one of \(n_1\) and \(n_2\) is relatively prime to \(N\). There are two cases: either \(N = 1\) and \(k \rightarrow \infty\) or \(k\) is fixed and \(N \rightarrow \infty\) through the primes. As \(x \sim \sqrt{k^2N}\), if \(N > 1\) then \(N\) does not divide \(m\) for sufficiently large \(N\). Thus we may assume \((n_2,N) = 1\). Using the multiplicativity of the Fourier coefficients, from the Petersson formula (Lemma A.3) we see that if \(p \mid n_1\) then there is negligible contribution unless \(p\) divides \(n_2\). From the definition of the multiplicative function \(\mu_f(h)\), we see immediately that \(h\) must be cube-free (if not, \(\mu_f(h) = 0\)). Thus we may write \(h = p_1 \cdots p_{r} q_1^2 \cdots q_{t}^2\) where \(p_1,\ldots,p_r\) are distinct primes, and \(\mu_f(h) = (-1)^r \lambda_f(p_1 \cdots p_r)\lambda_0(q_1^2 \cdots q_t^2)\). We immediately see that unless \(m\) is square-free and equal to \(p_1 \cdots p_r\) and the \(q_i\) are relatively prime to \(N\), the main term from \(\mu_f(h)\lambda_f(m)\) is zero. Further, the \(p_i\) must also be prime to \(N\), as \(p_i \leq m \leq x \sim \sqrt{k^2N}\).

Thus the only contribution from the \(m\) and \(h\)-sum is

\[
\prod_{p \leq x} \left( 1 - \frac{\lambda_f(p)^2}{p^{1+\alpha+\gamma}} + \frac{1}{p^{1+2\gamma}} \right) \prod_{p > x \atop p \not\mid N} \left( 1 + \frac{1}{p^{1+2\gamma}} \right). \tag{2.18}
\]

To see this, use multiplicativity to replace the sum in (2.17) with a product over primes, dropping all terms which will give a negligible contribution after applying the Petersson formula. For each prime \(p \leq x\) we either have 1, \(\mu_f(p)\lambda_f(p)\) or \(\mu_f(p^2)\lambda_f(1)\). The product over \(p > x\) arises from the fact that, for such large primes, we must either have 1 or \(\mu_f(p^2)\lambda_f(1)\) (as the \(m\)-sum is only up to primes at most \(x\), and the prime \(p = N\) can be ignored because \(\lambda_0(N) = 0\)). Thus when we use the Petersson formula we always have two Fourier coefficients relatively prime to the level \(N\). Summing over \(f \in H^*_{x}(N)\) allows us to replace \(\lambda_f(p^2)\) with 1 + small (and, as always, we ignore all ‘small’ terms), so the first half of \(R_{\mathcal{H}^*_{x}}(\alpha, \gamma)\) is

\[
\prod_{p \leq x} \left( 1 - \frac{1}{p^{1+\alpha+\gamma}} + \frac{1}{p^{1+2\gamma}} \right) \prod_{p > x \atop p \not\mid N} \left( 1 + \frac{1}{p^{1+2\gamma}} \right); \tag{2.19}
\]

see Remark 2.8 for an explanation as to why we have chosen to write this factor in this way.

As is customary in applications of the Ratios conjecture, we complete the \(m\)-sum by extending it to infinity. This is equivalent to sending \(x\) to infinity. Thus the first term of \(R_{\mathcal{H}^*_{x}}(\alpha, \gamma)\) is

\[
\prod_{p} \left( 1 - \frac{1}{p^{1+\alpha+\gamma}} + \frac{1}{p^{1+2\gamma}} \right). \tag{2.20}
\]

We now study the \(\lambda_f(N)\mu_f(h)\lambda_f(n)\) terms in (2.17), noting that \(N\) does not divide \(n\) (since \(n \leq y \sim \sqrt{k^2N}\)). There is thus negligible contribution unless \(N\mid h\). For \(p = N\) the factor is now

\[
\frac{\mu_f(N)}{N^{(1/2)+\gamma}} = \frac{\lambda_f(N)}{N^{(1/2)+\gamma}} \tag{2.21}
\]

(again, this factor is not present if \(N = 1\)). Remember we have a truncated sum, with \(n \leq y\). Thus for \(p \leq y\) the factors are the same as before (except we replace \(\alpha\) with \(-\alpha\), arising
from factors of 1, $\mu_f(p)\lambda_f(p)$ or $\mu_f(p^2)\lambda_f(1)$. However, for $y < p \neq N$ the factor is $1 + p^{-1-2\gamma}$ (arising from 1 or $\mu_f(p^2)$) there is no $\mu_f(p)\lambda_f(p)$ term as $p > y$). Thus our factors are

$$i^k \mu(N)\lambda_f(N) \sqrt{N} X_L \left( \frac{1}{2} + \alpha \right) \prod_{p \leq y} \left( 1 - \frac{\lambda_f(p)^2}{p^{1-\alpha + \gamma}} \right) \cdot \prod_{p > y, p \neq N} \left( 1 + \frac{1}{p^{1+2\gamma}} \right) \cdot \frac{-\lambda_f(N)}{N^{(1/2)+\gamma}}.$$ (2.22)

where, as before, the $N$-factor is present only if $N$ is prime. If $N > 1$ we replace $\lambda_f(N)^2$ with $1/N$, so when we apply the Petersson formula all Fourier coefficients will be relatively prime to the level $N$. If $N = 1$ we do not have this second factor of $\lambda_f(N)$; however, as $\lambda_f(1) = 1$, the resulting expression is the same.

Summing over $f \in H_k^e(N)$ allows us to replace the $\lambda_f(p)^2$ factors above with $1 + \text{small}$. Thus the product becomes

$$-i^k \mu(N) \sqrt{N} X_L \left( \frac{1}{2} + \alpha \right) \prod_{p \leq y} \left( 1 - \frac{1}{p^{1-\alpha + \gamma}} + \frac{1}{p^{1+2\gamma}} \right) \cdot \prod_{p > y} \left( 1 + \frac{1}{p^{1+2\gamma}} \right).$$ (2.23)

As before, we complete the $n$-sum by sending $y$ to infinity. We have deliberately pulled out the $p$-factor of $1/\zeta(1 - \alpha + \gamma)$ to improve the convergence of the remaining piece. We thus find that this factor is

$$-i^k \mu(N) \sqrt{N} X_L \left( \frac{1}{2} + \alpha \right) \cdot \frac{1}{\zeta(1 - \alpha + \gamma)} \prod_{p} \left( 1 + \frac{p^{1-\alpha + \gamma}}{p^{1+2\gamma}(p^{1-\alpha + \gamma} - 1)} \right).$$ (2.24)

Substituting the above completes the proof.

**Remark 2.7.** In the Ratios conjecture, the size of the error term is added in a somewhat ad-hoc manner. The predicted size of the error term is amazing, as it implies that the lower-order terms depending on the arithmetic of the family are calculated basically up to square-root cancellation in the family’s cardinality. As the recipe involves throwing away numerous remainders and arguing their aggregate does not matter, it is not possible to rigorously derive the size of the error term (unless, of course, we make significant progress towards proving the Ratios conjecture), and the standard assumptions in practice are that it is typically smaller than the main term by approximately the square-root of the family’s cardinality. See Remark 2.11 for additional comments on the discarded error terms.

**Remark 2.8.** We briefly discuss how we chose to write some of the factors above; we are thankful to the referee for pointing this out, and paraphrase the comments below. The usual convention in the Ratios conjecture is to pull out factors of zeta, which leaves a product over primes that is convergent when the shift parameters $\alpha$ and $\gamma$ are very small. When this is done, every orthogonal family Ratios conjecture looks the same, except for the convergent prime product, which is specific to the family; the polar structure of the terms is determined by the factors of zeta. For us, we could have pulled out a factor of $\zeta(1 + 2\gamma)/\zeta(1 + \alpha + \gamma)$ to leave something convergent for small $\alpha$ and $\gamma$. One expects this to be the same for every orthogonal family (for example, we can see the same factor in [3, equation (2.5)]). The structure of the zetas pulled out to ensure convergence is an identifying feature of the orthogonal symmetry as they mirror the structure of the random matrix result (compare the structure of the ratios of ‘$z$’s, the quantities called ‘$y$’, in [5, section 4] for different symmetry types). The number theory
results exactly mirror these RMT results. It is not always convenient to write the number theory results in this way when you want to calculate with them, but there is a universal structure there. This is similar to some of the computations in [19], where an alternate expression for the n-level density (different than the determinantal one from Katz–Sarnak [24, 25]) was derived to facilitate comparisons between the number theory and RMT).

**Lemma 2.9.** Let \( R_{H^r_k}(N)(r, r) = \frac{\partial}{\partial \alpha} R_{H^r_k}(N)(\alpha, \gamma) \bigg|_{\alpha=\gamma=r} \). Then for \( \Re r > 0 \) the Ratios conjecture predicts

\[
R'_{H^r_k}(N)(r, r) = \sum_p \frac{\log p}{p^{1+2r}} + \frac{i^k \mu(N)}{N^{1+r}} X_L \left( \frac{1}{2} + r \right) \prod_p \left( 1 + \frac{1}{(p-1)p^{2r}} \right) + O \left( |H_k^r(N)|^{-1/2+\epsilon} \right),
\]

(2.25)

where, as always, the \( N \)-factors are present only if \( N > 1 \).

**Proof.** We must differentiate the two terms in Lemma 2.6, and investigate the limit as \( y \to \infty \); see Lemma 2.2 for an explanation as to why the size of the error term is unaffected. The first term is easily handled. Using \( d \log f(\alpha)/d\alpha = f'(\alpha)/f(\alpha) \), we see that

\[
\frac{\partial}{\partial \alpha} \left[ \prod_p \left( 1 - \frac{1}{p^{1+\alpha+\gamma}} + \frac{1}{p^{1+2\gamma}} \right) \right] \bigg|_{\alpha=\gamma=r} = \prod_p \left( 1 - \frac{1}{p^{1+\alpha+\gamma}} + \frac{1}{p^{1+2\gamma}} \right) \bigg|_{\alpha=\gamma=r}
\]

\[
- \frac{i^k \mu(N) X_L \left( \frac{1}{2} + \alpha \right)}{N^{1+\gamma} \zeta(1 - \alpha + \gamma)} \prod_p \left( 1 + \frac{p^{1-\alpha+\gamma}}{p^{1+2\gamma}(p^{1-\alpha+\gamma} - 1)} \right),
\]

(2.27)

We use the following observation (see [3, p. 7]): if \( f(z, w) \) is analytic at \((z, w) = (r, r)\), then

\[
\frac{\partial}{\partial \alpha} \zeta(1 - \alpha + \gamma) \bigg|_{\alpha=\gamma=r} = -f(r, r).
\]

(2.28)

Thus the derivative of (2.27) with respect to \( \alpha \), evaluated at \( \alpha = \gamma = r \), is

\[
\frac{i^k \mu(N)}{N^{1+r}} X_L \left( \frac{1}{2} + r \right) \prod_p \left( 1 + \frac{1}{(p-1)p^{2r}} \right).
\]

(2.29)

**Remark 2.10.** If we do not extend the sums to infinity before differentiating, we get from Mertens’s theorem (see Appendix C) a factor of \( e^{-\gamma} \) in the second sum, where \( \gamma \) here is Euler’s constant. This is very interesting, as \( e^{-\gamma} \) is related to sieving primes. The sieving constant of \( e^{-\gamma} \) in the Mertens theorem is not 1, though for a generic sequence of random primes (also called the Hawkins primes) it is. While it is fascinating that there are two procedures which lead to different answers, this term is of size \( 1/N \), well beyond any plausible hope of testing. (This term is related to \( M(\phi) \). If \( N = 1 \) we can only show that \( M(\phi) \) is small for \( \sigma < 1/4 \),

\[
\]
though based on the number theory computations we expect it to be small for \( \sigma < 2 \) or even \( 22/9 \).) See \([1, 13, 15, 16, 34, 43]\) for some additional comments on \( e^{-\gamma} \).

**Remark 2.11.** We briefly comment on the size of the errors made at various steps in the Ratios conjecture. For example, consider the first piece of \( R_t^H(N, r, t) \), namely \( \sum_p \log p/p^{1+2r} \). This piece arose from a product originally over \( p \leq \sqrt{R} \) which we extended to be over all \( p \); thus the error between what we should have had and what we wrote is \( \sum_p \log p/p^{1+2r} \). We typically evaluate this when \( r = \epsilon + it \), and thus we have introduced an error of size \( O(R^{-\epsilon}) \). Thus while this is smaller than any power of \( 1/\log R \), it is significantly more than \( R^{-1/2+\epsilon} \). Thus this sizable error must be canceled by other errors if the Ratios conjecture is to yield the correct prediction.

3. **Weighted 1-level density from the Ratios conjecture**

3.1. **Main Expansion**

We now compute the 1-level density for the family \( H_k^N(N) \), with either \( N = 1 \) and \( k \to \infty \) or \( k \) a fixed even integer and \( N \) tending to infinity through the primes. We follow closely the arguments in \([3, 31]\).

**Lemma 3.1.** Assume GRH for \( \zeta(s) \) and all \( L(s, f) \) with \( f \in H_k^N(N) \), and let \( \phi \) be an even Schwartz function whose Fourier transform has compact support. Denote the weighted 1-level density for the family \( H_k^N(N) \) by

\[
D_{1, H_k^N(N); R}(\phi) = \sum_{f \in H_k^N(N)} \omega_f^*(N) \sum_{\gamma_j} \phi \left( \gamma_f \frac{\log R}{2\pi} \right). \tag{3.1}
\]

Assuming the Ratios conjecture, we have

\[
D_{1, H_k^N(N); R}(\phi) = 2 \sum_p \frac{\phi(2 \log p / \log R)}{\log p / \log R} \frac{\log p}{p \log R} + 2i^k \mu(N) / N \log R \times \int_{-\infty}^{\infty} X_L \left( \frac{1}{2} + \frac{2\pi it}{\log R} \right) \prod_{p \not\in \mathbb{P}} \left( 1 + 1 / (p-1)^{2\pi it / \log R} \right) e^{-2\pi it (\log N / \log R)} \phi(t) dt
\nonumber
\]

\[
+ \frac{1}{\log R} \int_{-\infty}^{\infty} \left( 2 \log \frac{\sqrt{N}}{\pi} + \psi \left( \frac{1}{4} + \frac{k+1}{4} + \frac{2\pi it}{\log R} \right) \right) \phi(t) dt + O \left( (kN)^{-1/2+\epsilon} \right). \tag{3.2}
\]

**Proof.** We first compute the unscaled, weighted 1-level density \( S_{1; H_k^N(N)}(g) \) for the family \( H_k^N(N) \) with \( g \) an even Schwartz function,

\[
S_{1; H_k^N(N)}(g) = \sum_{f \in H_k^N(N)} \omega_f^*(N) \sum_{\gamma_j} g(\gamma_f). \tag{3.3}
\]

Let \( c \in \left\{ (1/2) + 1/\log k^2 N, 3/4 \right\} \); thus

\[
S_{1; H_k^N(N)}(g) = \sum_{f \in H_k^N(N)} \frac{1}{2\pi i} \left( \int_{(c)} - \int_{(1-c)} \right) \omega_f^*(N) \frac{L'(s, f)}{L(s, f)} g \left( -i \left( s - \frac{1}{2} \right) \right) ds
\]

\[
= S_{1, c; H_k^N(N)}(g) + S_{1, 1-c; H_k^N(N)}(g). \tag{3.4}
\]
We argue as in [3, §3]. We first analyze the integral on the line $\Re(s) = c$. By GRH and the rapid decay of $g$, for large $t$ the integrand is small. We use the Ratios conjecture (Lemma 2.9 with $r = c - \frac{1}{2} + it$) to replace the term $\sum_f \omega_f(N) L'(s, f)/L(s, f)$ when $t$ is small. We may then extend the integral to all of $t$ because of the rapid decay of $g$. As the integrand is regular at $r = 0$ we can move the path of integration to $c = 1/2$. The contribution from the error term in the Ratios conjecture is negligible, due to $g$ being a Schwartz function. Thus the integral on the $c$-line is

$$S_{1,c; H_c(N)}(g) = \frac{1}{2\pi i} \int_{-\infty}^{\infty} g(t - i) \left( c - \frac{1}{2} \right) \sum_{f \in H_c(N)} \omega_f(N) \frac{L'((1/2) + (c - (1/2) + it), f)}{L((1/2) + (c - (1/2) + it), f)} i dt$$

$$= \frac{1}{2\pi} \int_{-\infty}^{\infty} g(t) \left[ \sum_p \frac{\log p}{p^{1+2it} + \frac{i^k \mu(N)}{N^{1+it}}} X_L \left( \frac{1}{2} + it \right) \prod_p \left( 1 + \frac{1}{(p-1)p^{2it}} \right) \right] dt + O((kN)^{-1/2+\epsilon}).$$

As

$$\int_{-\infty}^{\infty} g(t) p^{-2it} dt = \int_{-\infty}^{\infty} g(t) e^{-2\pi(2\log p/2\pi)^2} dt = g \left( \frac{2\log p}{2\pi} \right),$$

we have

$$S_{1,c; H_c(N)}(g) = \frac{1}{2\pi} \sum_p \tilde{g} \left( \frac{2\log p}{2\pi} \right) \log p + \frac{i^k \mu(N)}{2\pi N} \int_{-\infty}^{\infty} X_L \left( \frac{1}{2} + it \right)$$

$$\times \prod_p \left( 1 + \frac{1}{(p-1)p^{2it}} \right) N^{-it} g(t) dt + O((kN)^{-1/2+\epsilon}).$$

We now study $S_{1,1-c; H_c(N)}(g)$:

$$S_{1,1-c; H_c(N)}(g) = \sum_{f \in H_c(N)} \frac{-\omega_f(N)}{2\pi i} \int_{-\infty}^{\infty} \frac{L'(1 - (c + it), f)}{L(1 - (c + it), f)} g \left( -i \left( \frac{1}{2} - c \right) - t \right) (-i dt).$$

We use the functional equation

$$L(s, f) = \epsilon_f X_L(s)L(1 - s, f)$$

(3.9)

to find that

$$\frac{L'(1 - (c + it), f)}{L(1 - (c + it), f)} = -\frac{L'(c + it, f)}{L(c + it, f)} + \frac{X'_L(c + it)}{X_L(c + it)}. $$

(3.10)

This yields

$$S_{1,1-c; H_c(N)}(g) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \sum_{f \in H_c(N)} \frac{\omega_f(N)L'(c + it, f)}{L(c + it, f)} g \left( -i \left( \frac{1}{2} - c \right) - t \right) dt$$

$$- \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{X'_L(c + it)}{X_L(c + it)} g \left( -i \left( \frac{1}{2} - c \right) - t \right) dt.$$
The first term yields the same contribution as $S_{1,c:H^*_k(N)}(g)$; this follows by sending $c$ to $1/2$ and noting $g$ is an even function. Thus

$$S_{1,H^*_k(N)}(g) = \frac{2}{2\pi} \sum_p \hat{g} \left( \frac{2 \log p}{2\pi} \right) \frac{\log p}{p}$$

$$+ \frac{2ik\mu(N)}{2\pi N} \int_{-\infty}^{\infty} X_L \left( \frac{1}{2} + it \right) \prod_{p \neq N} \left( 1 + \frac{1}{(p-1)p^{2it}} \right) N^{-it} g(t) dt$$

$$- \frac{1}{2\pi} \int_{-\infty}^{\infty} X_L'(1/2 + it) g(t) dt + O \left( (kN)^{-1/2+\epsilon} \right). \quad (3.12)$$

In investigating zeros near the central point, it is convenient to renormalize them by the logarithm of the analytic conductor. Let $g(t) = \phi(t \log R/2\pi)$. A straightforward computation shows that $\hat{g}(\xi) = (2\pi/\log R) \phi(2\pi \xi/ \log R)$. The (scaled) weighted 1-level density for the family $H^*_k(N)$ is

$$D_{1,H^*_k(N);R}(\phi) = \sum_{f \in H^*_k(N)} \omega^*_f(N) \sum_{\gamma_f \in \gamma_f(N)} \phi \left( \frac{\gamma_f \log R}{2\pi} \right) = S_{1,H^*_k(N)}(g) \quad (3.13)$$

(where $g(t) = \phi(t \log R/2\pi)$ as before). Thus

$$D_{1,H^*_k(N);R}(\phi) = 2 \sum_p \hat{\phi} \left( \frac{2 \log p}{\log R} \right) \frac{\log p}{p \log R}$$

$$+ \frac{2ik\mu(N)}{2\pi N} \int_{-\infty}^{\infty} X_L \left( \frac{1}{2} + it \right) \prod_{p \neq N} \left( 1 + \frac{1}{(p-1)p^{2it}} \right) N^{-it} \phi \left( \frac{t \log R}{2\pi} \right) dt$$

$$- \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{X_L'(1/2 + it)}{X_L(1/2 + it)} \phi \left( \frac{t \log R}{2\pi} \right) dt + O \left( (kN)^{-1/2+\epsilon} \right). \quad (3.14)$$

Changing variables yields

$$D_{1,H^*_k(N);R}(\phi) = 2 \sum_p \hat{\phi} \left( \frac{2 \log p}{\log R} \right) \frac{\log p}{p \log R} + \frac{2ik\mu(N)}{N \log R}$$

$$\times \int_{-\infty}^{\infty} X_L \left( \frac{1}{2} + \frac{2\pi it}{\log R} \right) \prod_{p \neq N} \left( 1 + \frac{1}{(p-1)p^{2\pi it/\log R}} \right) e^{-2\pi it(\log N/\log R)} \phi(t) dt$$

$$- \frac{1}{\log R} \int_{-\infty}^{\infty} X_L' \left( \frac{1}{2} + \frac{2\pi it}{\log R} \right) \phi(t) dt + O \left( (kN)^{-1/2+\epsilon} \right). \quad (3.15)$$

Set $\psi(z) = \Gamma'(z)/\Gamma(z)$. As the derivative of $\log X_L(s)$ is $X_L'(s)/X_L(s)$, we find

$$- \frac{X_L' \left( (1/2) + \frac{2\pi it}{\log R} \right)}{X_L \left( (1/2) + \frac{2\pi it}{\log R} \right)} = 2 \log \frac{\sqrt{N}}{\pi} + \frac{1}{2} \psi \left( \frac{1}{4} + \frac{k \pm 1}{4} \pm \frac{2\pi it}{\log R} \right)$$

(note there are four $\psi$-terms). As $\phi$ is an even function, the $+$ and $-$ terms yield the same integral, completing the proof.

The first sum and the last integral in Lemma 3.1 will match up perfectly with terms from the number theory calculation. In §3.2 we conclude the proof of Theorem 1.2 by analyzing the middle term.

### 3.2. Proof of Theorem 1.2

**Proof of Theorem 1.2.** Most of the analysis for the first part of the theorem has been done in §3.1; in particular, the expansion in (3.15). The proof is completed by Lemmas 3.2
and 3.4 below, which derive a simpler expression for the middle piece and then show that it yields a negligible contribution.

**Lemma 3.2.** Let \( \Re(u) = 0 \). Then

\[
\prod_p \left( 1 + \frac{1}{(p-1)p^u} \right) = \frac{\zeta(2)}{\zeta(2+2u)} \cdot \zeta(1+u) \cdot \prod_p \left( 1 - \frac{p^u - 1}{p(p^{1+u}+1)} \right); \tag{3.17}
\]

note that the product over primes converges rapidly for \( \Re(u) = 0 \), as each term in the product is like \( 1 + O(1/p^2) \).

**Proof.** We have

\[
\prod_p \left( 1 + \frac{1}{(p-1)p^u} \right) = \prod_p \left( 1 + \frac{1}{p^{1+u}} \right) \cdot \left( 1 + \frac{1}{(p-1)(p^{1+u}+1)} \right)
\]

\[
= \prod_p \left( \frac{1 + (1/p^{1+u})}{1 - (1/p^{1+u})} \cdot \left( 1 + \frac{1}{(p-1)(p^{1+u}+1)} \right) \right)
\]

\[
= \frac{\zeta(1+u)}{\zeta(2+2u)} \cdot \prod_p \left( 1 + \frac{1}{(p-1)(p^{1+u}+1)} \right). \tag{3.18}
\]

We can rewrite this a little further, using

\[
\prod_p \left( 1 + \frac{1}{(p-1)(p^{1+u}+1)} \right) = \prod_p \frac{p^2}{p^2 - 1} \cdot \left( 1 - \frac{p^u - 1}{p(p^{1+u}+1)} \right)
\]

\[
= \prod_p \frac{1}{1 - (1/p^2)} \cdot \left( 1 - \frac{p^u - 1}{p(p^{1+u}+1)} \right)
\]

\[
= \zeta(2) \prod_p \left( 1 - \frac{p^u - 1}{p(p^{1+u}+1)} \right). \tag{3.19}
\]

Substituting this into (3.18) completes the proof. \(\square\)

**Remark 3.3.** When arguing along the lines of the Ratios conjecture, it often greatly simplifies the calculations to rewrite the prime products in a more rapidly convergent manner by factoring out zeta or \( L \)-functions. In Lemma B.1 we use the above expansion to show that the \( X_L \) term in the 1-level density is negligible. When \( N = 1 \), this is the hardest part of the proof, and follows by shifting contours.

**Lemma 3.4.** Let

\[
M(\phi) = \frac{2\pi^k \mu(N)}{N \log R} \left[X_L \left( \frac{1}{2} + \frac{2\pi it}{\log R} \right) \frac{\zeta(2)}{\zeta(2 + (8\pi it/\log R))} \zeta \left( 1 + \frac{4\pi it}{\log R} \right) \right]
\]

\[
\cdot \prod_p \left( 1 - \frac{p^{4\pi it/(\log R) + 1}}{p(p^{1+4\pi it/(\log R)} - 1)} \right) e^{-2\pi it(\log N/\log R)} \phi(t) \, dt. \tag{3.20}
\]

If \( N > 1 \) we have \( M(\phi) = O(1/N) \). Assume \( \text{supp}(\hat{\phi}) \subset (-\sigma, \sigma) \). If \( N = 1 \) then \( M(\phi) = O \left( 2009^k \cdot k^{-(1 - 4\sigma)/(3k)} \right) \), which tends to zero more rapidly than \( k^{-\delta} \) for any \( \delta > 0 \) for \( \sigma < 1/4 \).

**Proof.** We use the lemmas from Appendix B to bound the relevant quantities. As \( \phi \) is an even function, there is no contribution from the pole of the Riemann zeta function.
Assume first \( N > 1 \). If \( u \geq 0 \) then
\[
\left| \zeta \left( 2 + 2u + \frac{8\pi it}{\log R} \right) \right| \geq 1 - \sum_{n=2}^{\infty} \frac{1}{n^2} = 1 - \left( \frac{\pi^2}{6} - 1 \right) > 0. \tag{3.21}
\]

As remarked above, there is no contribution from the pole of the Riemann zeta function (since \( \phi \) is even). We may thus subtract off the pole without changing the value of the integral, and note that
\[
\left| \zeta \left( 1 + \frac{4\pi it}{\log R} \right) - \frac{\log R}{4\pi it} \right| \ll (t^2 + 1) \log R \tag{3.22}
\]

(we could of course do far better, but a very weak bound suffices for large \( t \) due to the rapid decay of \( \phi \)). Thus the product of the zeta terms is \( O((t^2 + 1) \log N) \). The product over primes is bounded by
\[
\prod_p \left( 1 - \frac{2}{p(p-1)} \right), \tag{3.23}
\]
which is \( O(1) \). Finally, the \( X_L \)-term is \( O(1) \) by Lemma B.1. Thus
\[
M(\phi) \ll \frac{1}{N \log R} \int_{-\infty}^{\infty} (t^2 + 1) \log R \cdot \phi(t) \, dt \ll \frac{1}{N} \tag{3.24}
\]
(as \( \phi \) is a Schwartz function).

Assume now that \( N = 1 \). We follow the method used in \([31]\), and replace \( t \) with \( t - iw(\log R/4\pi) \) (where initially \( w = 0 \)), shift contours and exploit the decay in \( w \). By analyzing \( X_L \) and the zeta factors, we may shift the contour to \( w = 2k - 1 - \epsilon \) without passing through any zeros or poles. We shift to \( w = (2k - 1)/3 \), as this will simplify some of the computations. We have
\[
M(\phi) = -2t^k \log R \int_{-\infty}^{\infty} X_L \left( \frac{1 + w}{2} + \frac{2\pi it}{\log R} \right) \frac{\zeta(2)}{\zeta(2 + 2w + 8\pi it/\log R)} \zeta \left( 1 + w + \frac{4\pi it}{\log R} \right) \cdot A \left( w + \frac{2\pi it}{\log R} \right) \cdot \phi \left( t - iw \frac{\log R}{2\pi} \right) \, dt, \tag{3.25}
\]
where
\[
A(x + iy) = \prod_p \left( 1 - \frac{p^{x+iy} - 1}{p^{1+x+iy} + 1} \right). \tag{3.26}
\]
As \( \phi \) is even, there is no contribution from the pole of the zeta function. In the arguments below, we could be more explicit and subtract off this pole. The shifted term will have a factor of size \( O \left( (w^2 + (t/\log R)^2)^{-1} \right) = O(1) \), which will not change any of the arguments.

From Lemma B.4 we have \( A(w + 2\pi it/\log R) = O(1) \). For any \( w > 0 \), by (3.21) the ratio of the zeta factors \( \zeta(2)/\zeta(2 + 2w + 8\pi it/\log R) \) is \( O(1) \). From Lemma B.1 we know that for \( w = (2k - 1)/3 \) the \( X_L \)-term is \( O(2009^k \cdot k^{-k/3}) \), and from Lemma B.3 we have
\[
\phi \left( t - iw \frac{\log R}{2\pi} \right) \ll \exp (\sigma w \log R) \cdot \left( t^2 + \frac{\log^2 R}{16\pi^2} \right)^n \ll \frac{R^{\sigma w}}{(t^2 + 1)^n}. \tag{3.27}
\]
Thus
\[
M(\phi) \ll \left( 2009^k \cdot k^{-k/3} \right) \frac{R^{\sigma w}}{\log R} \int_{-\infty}^{\infty} \frac{dt}{(t^2 + 1)^n} \ll \frac{2009^k R^{\sigma w}}{k^{k/3} \log R}. \tag{3.28}
\]
For cuspidal newforms of level 1 and weight \( k \), one takes (see \([23, (1.14) \text{ and } (4.29)]\)) \( R \sim k^2 \). As \( w = (2k - 1)/3 \), the above decays more rapidly than
\[
2009^k \cdot k^{4k\sigma/3 - k/3} = 2009^k \cdot k^{-(1-4\sigma)/3}k; \tag{3.29}
\]
thus as long as $\sigma < 1/4$, this term decays faster than $k^{-\delta}$ for any $\delta > 0$.

Remark 3.5. Note that the results in Lemma 3.4 are significantly worse for $N = 1$ than for $N \to \infty$. (In fact, for $N \to \infty$ the Ratios conjecture states that we should not include $M(\phi)$. We only have it as we are using a weaker version of the conjecture; see Remark 1.8 for additional details.) This is due to the rapid growth of $\phi(x + iy)$ in $y$, and leads to a significantly reduced support. This is very similar to the difficulties encountered in studying families of quadratic characters [31], where we again had to perform a contour shift, which restricted our results to $\sigma < 1$ (with square-root agreement for $\sigma < 1/3$). Our result is weaker than the corresponding result in [31] (we have $\sigma < 1/4$ instead of $\sigma < 1$) because here the conductor is $k^2$ (whereas in [31] the conductor is $d$) and $k$ appears in the Gamma factors.

Remark 3.6. Another approach to analyzing $M(\phi)$ when $N = 1$ is to shift the contour very far to the right, picking up contributions from the poles of the Gamma function in the numerator of the Ratios conjecture states that we should not include $M(\phi)$, but we have it as we are using a weaker version of the conjecture; see Remark 1.8 for additional details.) This is due to the rapid growth of $\phi(x + iy)$ in $y$, and leads to a significantly reduced support. This is very similar to the difficulties encountered in studying families of quadratic characters [31], where we again had to perform a contour shift, which restricted our results to $\sigma < 1$ (with square-root agreement for $\sigma < 1/3$). Our result is weaker than the corresponding result in [31] (we have $\sigma < 1/4$ instead of $\sigma < 1$) because here the conductor is $k^2$ (whereas in [31] the conductor is $d$) and $k$ appears in the Gamma factors.

4. Weighted 1-level density from the number theory

We now determine the main and lower-order terms in the 1-level density for the family $H_k^*(N)$ for as large support as possible for the Fourier transform of the test function. In [23] the main term is determined for $\text{supp}(\phi) \subset (-2, 2)$; however, as the authors are only concerned with the main term they are a little crude in bounding the error terms. We perform a more careful analysis below.

In [23, Section 4] the explicit formula is used to compute the 1-level density for the family $H_k^*(N)$. In that paper $Q = \sqrt{N}/\pi$. Noting that $\phi(0) = \int_{-\infty}^{\infty} \phi(t) dt$, we may rewrite the weighted sum over $f \in H_k^*(N)$ of [23, equation (4.11)] as

$$D_{1, H_k^*(N); R}(\phi) = \frac{1}{\log R} \int_{-\infty}^{\infty} \left( 2 \log \frac{\sqrt{N}}{\pi} + \psi \left( \frac{1}{4} + \frac{k \pm 1}{4} + \frac{2\pi it}{\log R} \right) \right) \phi(t) dt$$

$$- 2 \sum_{f \in H_k^*(N)} \sum_{p} \frac{\alpha_f(p) + \beta_f(p)}{p^{\nu/2}} \frac{\phi(\nu \log p)}{\log R} \log p,$$

where

$$L(s, f) = \prod_{n=1}^{\infty} \frac{\lambda_f(n)}{n^s} = \prod_p \left( 1 - \frac{\alpha_f(p)}{p^s} \right)^{-1} \left( 1 - \frac{\beta_f(p)}{p^s} \right)^{-1}.$$
Note that the first term agrees exactly with the last term from the Ratios conjecture (Theorem 1.2).

The following identities for the Fourier coefficients (for \( p \not| N \)) are standard:

\[
\lambda_f(p) = \alpha_f(p) + \alpha_f(p)^{-1}, \quad [\alpha_f(p)] = 1, \quad \alpha_f(p)^{-1} = \beta_f(p),
\]

\[
\lambda_f(p^\nu) = \alpha_f(p^\nu) + \alpha_f(p)^{-\nu^2} + \ldots + \alpha_f(p^{2-\nu}) + \alpha_f(p^{-\nu}),
\]

\[
\alpha_f(p^\nu) + \alpha_f(p)^{-\nu} = \lambda_f(p^\nu) - \lambda_f(p^{-\nu}). \tag{4.3}
\]

Trivially bounding the contribution from \( p = N \), we may thus rewrite \( D_{1,H^*_f(N);R}(\phi) \) as

\[
D_{1,H^*_f(N);R}(\phi) = \frac{1}{\log R} \int_{-\infty}^{\infty} \left( 2 \log \frac{\sqrt{N}}{\pi} + \psi \left( \frac{1}{4} + \frac{k \pm 1}{4} + \frac{2\pi it}{\log R} \right) \right) \hat{\phi}(t) \, dt
\]

\[
- 2 \sum_{f \in H^*_f(N)} \omega_f^*(N) \sum_{p \not| N} \frac{\lambda_f(p)}{2 \log \frac{p}{\log R}} 
\]

\[
- 2 \sum_{f \in H^*_f(N)} \omega_f^*(N) \sum_{p \not| N} \frac{\lambda_f(p^2) - 1}{p} \hat{\phi} \left( \frac{2 \log p}{\log R} \right) \frac{\log p}{\log R}
\]

\[
- 2 \sum_{f \in H^*_f(N)} \omega_f^*(N) \sum_{p \not| N} \sum_{\nu=3}^{\infty} \frac{\lambda_f(p^\nu) - \lambda_f(p^{-\nu})}{p^{\nu/2}} \hat{\phi} \left( \nu \frac{\log p}{\log R} \right) \frac{\log p}{\log R}
\]

\[
+ O \left( \frac{1}{\sqrt{N}} \right)
\]

\[
= \frac{1}{\log R} \int_{-\infty}^{\infty} \left( 2 \log \frac{\sqrt{N}}{\pi} + \psi \left( \frac{1}{4} + \frac{k \pm 1}{4} + \frac{2\pi it}{\log R} \right) \right) \hat{\phi}(t) \, dt
\]

\[
+ 2 \sum_p \frac{1}{p} \hat{\phi} \left( \frac{2 \log p}{\log R} \right) \log \frac{p}{\log R} - S_1(\phi) - S_2(\phi) - S_3(\phi) + O \left( \frac{1}{\sqrt{N}} \right) \tag{4.4}
\]

where

\[
S_1(\phi) = 2 \sum_{f \in H^*_f(N)} \omega_f^*(N) \sum_{p \not| N} \frac{\lambda_f(p)}{2 \log \frac{p}{\log R}} \hat{\phi} \left( \frac{2 \log p}{\log R} \right) \frac{\log p}{\log R},
\]

\[
S_2(\phi) = 2 \sum_{f \in H^*_f(N)} \omega_f^*(N) \sum_{p \not| N} \frac{\lambda_f(p^2) - 1}{p} \hat{\phi} \left( \frac{2 \log p}{\log R} \right) \frac{\log p}{\log R},
\]

\[
S_3(\phi) = 2 \sum_{f \in H^*_f(N)} \omega_f^*(N) \sum_{p \not| N} \sum_{\nu=3}^{\infty} \frac{\lambda_f(p^\nu) - \lambda_f(p^{-\nu})}{p^{\nu/2}} \hat{\phi} \left( \nu \frac{\log p}{\log R} \right) \frac{\log p}{\log R}. \tag{4.5}
\]

The first and the second terms above perfectly match with terms from the Ratios conjecture. We must therefore show that the other three terms are negligible. We prove Theorems 1.4 and 1.6 in stages below; we first perform the analysis for limited support, and then extend the support by assuming various conjectures.

4.1. **Density theorem limited**

As the arguments are similar when \( N \to \infty \) through the primes and when \( N = 1 \) and \( k \to \infty \), we give complete details for \( N \to \infty \) and sketch the arguments when \( N = 1 \).

**Remark 4.1.** It is important to note that we have included the harmonic (or Petersson) weights in our family to facilitate applications of the Petersson formula. When using results...
from Iwaniec, Luo and Sarnak [23], one must be careful as they have three related quantities involving averages of the Fourier coefficients over families. The first (converting to our notation)
is their equation (2.7),
\[ \Delta_k(m, n) = \sum_{f \in B_k(N)} \omega_f(N) \lambda_f(m) \lambda_f(n); \] (4.6)
the weights sum to 1, and thus in this expression we have effectively divided by the cardinality of the family. Note that we are summing over all cusp forms of weight \( k \) and level \( N \), and not just the newforms. The second is their equation (2.54), where we sum over just the newforms:
\[ \Delta_{k,N}^\sigma(m, n) = \zeta(2) \sum_{f \in H_k^\sigma(N)} \frac{\lambda_f(m) \lambda_f(n)}{L(1, \text{sym}^2 f)}, \quad \sigma \in \{*, +, -\}. \] (4.7)
Finally, we have the unweighted, pure sums (their equation (2.59)):
\[ \Delta_{k,N}^\sigma(n) = \sum_{f \in H_k^\sigma(N)} \lambda_f(n), \quad \sigma \in \{*, +, -\}. \] (4.8)
Much effort was spent in [23] to remove the weights; thus when reading the paper we must look carefully to see which variant the authors have used.

**Lemma 4.2.** Let \( \text{supp}(\hat{f}) \subset (-\sigma, \sigma) \). Then \( S_1(\phi) \ll N^{\sigma-(3/2)+\epsilon} + N^{(\sigma/2)-1+\epsilon} \) as \( N \to \infty \) through the primes, and if \( \sigma < 1 \) then \( S_1(\phi) \ll k^{2\sigma}2^{-k} \) for \( N = 1 \) and \( k \to \infty \).

**Proof.** Assume that \( N > 1 \) tends to infinity through the primes. We use the Petersson formula (Lemma A.4) to bound the weighted sum of \( \lambda_f(p) \), and find that
\[ S_1(\phi) \ll 2 \sum_{p \not\equiv N} \frac{\log R}{\sqrt{p}} \left( \frac{\sqrt{p}}{\sqrt{N} + \sqrt{p}} + (pN)^\epsilon \right). \] (4.9)
As \( 1/\sqrt{N} + \sqrt{p} \ll 1/\sqrt{N} \), we find that
\[ S_1(\phi) \ll \sum_{p \ll k^2} \frac{\log N}{N \sqrt{N}} + N^{\epsilon' + (\sigma/2) - 1} \ll N^{\sigma - (3/2) + \epsilon} + N^{(\sigma/2) - 1 + \epsilon}. \] (4.10)
If now \( N = 1 \) and \( k \to \infty \), we use Lemma A.3 (which forces us to take \( \sigma < 1 \) as \( R = k^2 \)) and find that
\[ S_1(\phi) \ll \frac{1}{2k} \sum_{p \ll k^2} \frac{\log p}{\log R} \ll k^{2\sigma}2^{-k}, \] (4.11)
which is \( O(k^{-1/2}) \) for \( k \) large.

**Remark 4.3.** In the next lemma we shall see that \( S_2(\phi) \) and \( S_3(\phi) \) are extremely small if \( \sigma < 2 \). If \( \sigma < 1 \), then \( S_1(\phi) \ll N^{-1/2} \) or \( k^{-1/2} \), and we obtain square-root agreement of this term with the Ratios prediction (if \( N = 1 \) we must restrict to \( \sigma < 1/4 \) because of our estimate for \( M(\phi) \)). For \( \sigma \geq 1 \) we do not have such phenomenal agreement (we can take \( \sigma < 3/2 \) for \( N \to \infty \), but if \( k \to \infty \) the above arguments fail for \( \sigma \geq 1 \)), but we do at least agree up to a power of \( N \). We have not exploited any cancelation in the Bessel–Kloosterman terms (we shall do this in §4.2), contenting ourselves here to argue simply and crudely. The quality of our results is exactly the same as that in [23, Theorem 5.1] (where the authors have not yet exploited properties of the Bessel–Kloosterman terms, which is required to increase the support).
LEMMA 4.4. Let supp(\(\hat{\phi}\)) \(\subset (-\sigma, \sigma)\).

(i) We have \(S_2(\phi) \ll N^{(\sigma/4)-1+\epsilon''} \) as \(N \to \infty\) through the primes, and \(S_2(\phi) \ll k^{-(5-3\sigma)/6+\epsilon}\) if \(N = 1\) and \(k \to \infty\).

(ii) We have \(S_3(\phi) \ll N^{(\sigma/12)-1+\epsilon''} \) as \(N \to \infty\) through the primes, and \(S_3(\phi) \ll k^{-(5-\sigma)/6+\epsilon}\) if \(N = 1\) and \(k \to \infty\).

Proof. As the proofs are similar, we only prove the second statement. We first consider \(N \to \infty\). We apply the Petersson formula (Lemma A.4) to the sums of \(\lambda_f(p^\nu)\) and \(\lambda_f(p^{\nu-2})\).

As the error from the \(\lambda_f(p^{\nu-2})\) terms is dominated by the error from the \(\lambda_f(p^\nu)\) terms, we only consider the former. As we evaluate \(\hat{\phi}\) at \(\nu \log p / \log R\) with \(n \geq 3\), we may restrict the \(p\)-sums to \(p \leq R^{\sigma/3}\) (where \(R = k^2 N\)). We find that

\[
S_3(\phi) \ll \sum_{\substack{(p, N) = 1 \atop p \leq R^{\sigma/3}}} \log_k R \sum_{\nu=3}^{\log_2 R} \frac{1}{p^{\nu/2}} \left( \frac{\log N}{N} \frac{p^{\nu/2}}{p^{\nu/2} + \sigma} + \frac{\nu N}{p^{\nu/2}} \right)
\]

\[
\ll \log^2 N \sum_{\substack{p \leq R^{\sigma/3}}} p^{-3/4 + \epsilon} + N^{\epsilon'} - 1
\]

\[
\ll N^{(\sigma/12)-1+\epsilon} + N^{\epsilon'} - 1 \ll N^{(\sigma/12)-1+\epsilon''}. \tag{4.12}
\]

We now examine the case when \(N = 1\) and \(k \to \infty\). We use Lemma A.2. As \(R = k^2\) and \(\nu \geq 3\), the prime sum is restricted to \(p \leq k^{2\sigma/3}\). We find

\[
S_3(\phi) \ll \log^2 k \sum_{\substack{p \leq k^{2\sigma/3}}} \frac{1}{k^{5/6}} \frac{1}{\sqrt{p^{\nu/2} + k}} \ll k^{-5/6 + \epsilon} \sum_{\substack{p \leq k^{2\sigma/3}}} p^{-3/4} \ll k^{-(5-\sigma)/6+\epsilon}. \tag{4.13}
\]

\[\square\]

REMARK 4.5. Even for \(\sigma < 6\) (which is well beyond current technology for analyzing \(S_1(\phi)\)), \(S_3(\phi)\) is \(O(N^{-1/2})\); it is \(O(k^{-1/2})\) for \(\sigma < 2\), which is in the range of current technology. If \(N > 1\) then \(S_2(\phi) = O(N^{-1/2+\epsilon})\) for \(\sigma < 2\); however, if \(N = 1\) then we only have square-root cancelation up to \(\sigma = 2/3\) (in fact, if \(\sigma \geq 5/3\) then our argument is too crude to bound this term). Thus the difficulty in showing agreement between the number theory and the Ratios conjecture’s predictions is entirely due to \(S_1(\phi)\) on the number theory side and \(M(\phi)\) on the Ratios side.

4.2. Density theorem extended

To improve our 1-level density results for \(H_k^*(N)\), we need to improve our analysis of

\[
S_1(\phi) = 2 \sum_{f \in H_k^*(N)} \omega_f^*(N) \sum_{\substack{p \neq N \atop \nu \leq p}} \frac{\lambda_f(p)}{\sqrt{p}} \frac{\phi(p)}{\phi(R)} \frac{\log p}{\log R}. \tag{4.14}
\]

We are able to show agreement with the Ratios conjecture up to a power savings in \(N\) if \(\text{supp}(\hat{\phi}) \subset (-\sigma, \sigma)\) with \(\sigma < 2\) (with additional analysis of \(S_2(\phi)\) we should be able to extend our results up to \(\sigma < 2\) when \(N = 1\)). To do this we modify the arguments in [23]. There are two major differences. First, the authors of [23] were concerned only with the main term and \(N\) square-free, and thus some of their error terms can be significantly improved for \(N\) prime. Second, they studied the unweighted sum (that is, they did not include the Petersson weights). Including the Petersson weights simplifies the computations, though they can be done with the unweighted sum as well (see §5).
Lemma 4.6. Assume GRH for \( \zeta(s) \), all Dirichlet \( L \)-functions and all \( L(s, f) \) with \( f \in S_k(N) \). If \( N \to \infty \) through the primes then \( S_1(\phi) \ll N^{(\sigma/2)-1+\varepsilon} \).

Proof. The most difficult part in the proofs in [23] was from handling the non-diagonal terms in the unweighted Petersson formula. We bypass some of these difficulties by using weighted sums. We have

\[
S_1(\phi) = \sum_{p \neq N} \left( \sum_{f \in \mathcal{H}_{k}^c(N)} \omega_f(N) \lambda_f(p) \right) \phi \left( \frac{\log p}{\log R} \right) \frac{2 \log p}{\sqrt{p} \log R}. \tag{4.15}
\]

Let

\[
Q_k^*(m; c) = 2\pi \rho k \sum_{p^\delta \leq c} S(m^2, p; c) J_{k-1} \left( \frac{4\pi m \sqrt{p}}{c} \right) \phi \left( \frac{\log p}{\log R} \right) \frac{2 \log p}{\sqrt{p} \log R}. \tag{4.16}
\]

Applying the Petersson formula (Lemmas A.1 and A.4) to \( S_1(\phi) \) yields

\[
S_1(\phi) = \sum_{c \equiv 0 \mod N} \frac{Q_k^*(1; c)}{c} + O \left( \frac{P^{3/2}}{N^{1+\varepsilon}} \right). \tag{4.17}
\]

This is very similar to the sum \( \mathcal{P}^*_k(\phi) \) in [23, equation (5.15)], with \( X = Y = 1 \), \( L = 1 \), \( M = N \). The difference is that (5.15) has an extra factor of \( (k-1)N/12 \), which is basically the cardinality of \( \mathcal{H}_{k}^c(N) \). We can use the results from [23, Sections 5 through 7] to bound \( Q_k^*(1; c) \). We have (see [23, (7.1)]) that

\[
Q_k^*(m; c) \ll \tilde{\gamma}_k(z) m P^{1/2} (kN)^{\varepsilon} (\log 2c)^{-2}, \tag{4.18}
\]

where \( R = k^2 N \), \( P = R^\sigma \), \( z = 4\pi m \sqrt{P}/c \) and \( \tilde{\gamma}(z) = 2^{-k} \) if \( 3z \leq k \) and \( k^{-1/2} \) otherwise. Thus

\[
S_1(\phi) \ll \sum_{c \equiv 0 \mod N} \frac{(k^2 N)^{\sigma/2} (kN)^{\varepsilon}}{c(\log 2c)^2} + N^{(\sigma/2)-1+\varepsilon} \ll N^{(\sigma/2)-1+\varepsilon} \tag{4.19}
\]

(write \( c = c'N \), which is negligible so long as \( \sigma < 2 \)).

Remark 4.7. We briefly comment on where we use GRH for Dirichlet \( L \)-functions. If \( \chi \) is a character modulo \( c \), then under GRH we have

\[
\sum_{p \leq x} \chi(p) \log p = \delta_\chi x + O \left( x^{1/2} \log^2 x \right), \tag{4.20}
\]

where \( \delta_\chi = 1 \) if \( \chi \) is the principal character and 0 otherwise. In [23, Section 6] they expand the Kloosterman sum. Setting

\[
G_\chi(n) = \sum_{a \mod c} \chi(a) e^{2\pi i a n/c}, \tag{4.21}
\]

we find

\[
\sum_{p \leq x} \frac{S(m, np; c)}{\varphi(c)} \frac{1}{(\chi \mod c)} \chi(a) S(m, an; c) \sum_{p \leq x} \chi(p) \log p \left( \frac{\delta_\chi x + O \left( x^{1/2} \log^2 x \right)}{4\pi m \sqrt{p}} \right) \left( 2 \log p \right) \phi \left( \frac{\log p}{\log R} \right) \frac{2 \log p}{\sqrt{p} \log R}.
\]

If we did not assume GRH, the error term above would have to be replaced with something significantly larger. This estimate is a key input in the bound for \( Q_k^*(m; c) \).
LEMMA 4.8. Assume GRH for ζ(s), all Dirichlet L-functions and all L(s, f). Let supp(ϕ̂) ⊂ (−σ, σ) with σ < 2, N = 1, and consider the 1-level density averaged over the weights (see Theorem 1.6 for an explicit statement). As K → ∞ the 1-level density agrees with the prediction from the Ratios conjecture up to errors of size O(K^{-(5−σ)/4+ε} + K^{σ−2+ε}).

Proof. As the proof is similar to our previous results, we merely highlight the differences. Following [23, Sections 8 and 9], we average over the weights as follows. Let h be a Schwartz function compactly supported on (0, ∞). The weighted 1-level density is

$$A^*(K; φ) = \frac{1}{A^*(K)} \sum_{k \equiv 0 \mod 2} 24 \frac{k−1}{K} \sum_{f \in H^*_K(1)} D_{1, H^*_K(1)} k^2(φ),$$

where

$$A^*(K) = \sum_{k \equiv 0 \mod 2} 24 \frac{k−1}{K} |H^*_K(1)| = \hat{h}(0)K + O(K^{2/3}).$$

The only pieces whose errors cannot be trivially added arise from $S_1(φ)$ and $S_2(φ)$ for each k; we now discuss how to handle these weighted averages. (Actually, we need to be a little more careful. The problem is that the analytic conductors are no longer constant; if supp(h) ⊂ (a, b) then the conductors basically run from (aK)² to (bK)². Fortunately, an analysis of our previous arguments show that we do not need to localize the conductor exactly, but instead only up to a constant (see also [23, equations (4.29) and (4.30)], and the comments immediately after). Thus we may set $R = K^2$. The varying conductors here are significantly easier to handle than in other families, such as one-parameter families of elliptic curves [29].) The main idea is to exploit the oscillation in the Bessel functions as k varies. The argument is easier than that in [23] due to the presence of the harmonic weights, though a similar result holds if we remove the weights (see §5).

We first handle the average of $S_1(φ)$. Averaging over k allows us to exploit the oscillation in the Bessel functions; this is the reason we are able to double the support. The main input is [23, Corollary 8.2], which says that

$$I(x) = \sum_{k \equiv 0 \mod 2} 2^k h \left( \frac{k−1}{K} \right) J_{k−1}(x) \ll xK^{-4},$$

where $x = 4πm\sqrt{p}/c$, $P = R^σ = K^{2σ}$, and for us $m = 1$ (as Iwaniec, Luo and Sarnak [23] removed the harmonic weights, they had a sum over $m ≤ Y$). Corollary 8.2 requires $x ≪ K^{2−ε}$, that is, $σ < 2 − ε$. The analysis of the average of $S_1(φ)$ is completed by feeding in the estimate from [23, equation (8.11)], which yields a bound of $K^{σ+ε−2}$ (remember we already executed the summation over k when we bounded $I(x)$). Thus the total error from the sum over k of the $S_1(φ)$ terms is $O(K^{σ+ε−2})$.

We now consider the average of $S_2(φ)$. There are two major differences between this term and $S_1(φ)$. The first is that the Kloosterman sums are $S(1, p^2; c)$ instead of $S(1, p; c)$. The second is that we have $ϕ̂(2\log p/\log R) (\log p/\log R)$ instead of $ϕ̂(\log p/\log R) (\log p/\sqrt{p}\log R)$; this leads to a shorter prime sum of smaller terms. We can modify the arguments in [23, Section 9] (remembering, as in Lemma 4.6, that our sum is simpler as $L = X = Y = m = M = 1$). Performing the averaging over k yields

$$\sum_{c} \frac{Q^{(2)}(1; c)}{c},$$

where

$$Q^{(2)}(1; c) = 2π \sum_{p \neq N} S(1, p^2; c) I \left( \frac{4πp}{c} \right) \hat{ϕ} \left( \frac{2\log p}{\log R} \right) \frac{2\log p}{p\log R}.$$
and \( I(x) \) is the sum of Bessel functions (see [23, equation (8.7)]). By [23, Corollary 8.2] we have
\[
I(x) = -\frac{K}{\sqrt{x}} \text{Im} \left\{ \zeta s e^{ix} h \left( \frac{K^2}{2x} \right) \right\} + O \left( \frac{x}{K^4} \right). \tag{4.28}
\]

The error term yields to an insignificant contribution to \( \sum_{c} Q^{(2)}(1;c)/c \) (much less than in [23], due to the remarks above). Trivially estimating the Kloosterman sum by \( e^{1/2+\epsilon} \) and recalling \( R = K^2 \) yields a contribution of
\[
\sum_{c=p \in R^{\sigma/2}} \frac{1}{c} \sum_{p \leq R^{\sigma/2}} c^{(1/2)+\epsilon} \frac{p^{1+\epsilon}}{cK^4} \ll K^{\sigma-4}, \tag{4.29}
\]
which is negligible for \( \sigma < 4 \) (and smaller than \( O(K^{-1/2}) \) for \( \sigma < 3.5 \)).

We now study the main term of \( Q^{(2)}(1;c) \). Following [23] it is
\[
Q^{(2)}(1;c) = -\frac{2K}{\log R} T(1;c), \tag{4.30}
\]
where
\[
T(1;c) = \sum_{p \neq N} S(1,p^2;c) \text{Im} \left\{ \zeta s \exp \left( \frac{4\pi ip}{c} \right) h \left( \frac{cK^2}{8\pi p} \right) \hat{\phi} \left( \frac{2 \log p}{\log R} \right) \frac{\log p}{p^{3/2}}, \right\}
\]
\[
h(v) = \int_{0}^{\infty} \frac{h(\sqrt{u})}{\sqrt{2\pi u}} e^{ivu} du. \tag{4.31}
\]

We do not need as delicate an analysis as in [23]. This is because of the extra \( \sqrt{p} \) in the denominator and the fact that the prime sums are up to \( R^{\sigma/2} \) and not \( R^{\sigma} \). We trivially estimate the Kloosterman sums and use the bound on \( h \) from [23]: for any \( A > 0 \), we have \( h(v) \ll v^{-A} \). Taking \( A = 1 + \delta \) yields
\[
T(1;c) \ll \sum_{p \leq R^{\sigma/2}} c^{(1/2)+\epsilon} \frac{p^{1+\delta} \log p}{c^{4+\delta}K^{2+2\delta}} \frac{\log p}{p^{3/2}} \ll K^{(\sigma/2)+\sigma\delta-2-2\delta} \frac{K^{(1/2)+\delta}}{c^{(1/2)+\delta-\epsilon}}. \tag{4.32}
\]

We substitute this into (4.26), and find a contribution bounded by
\[
\sum_{c} K \sqrt{c} K^{(\sigma/2)+\sigma\delta-2-2\delta} \frac{c^{(1/2)+\delta}}{c^{(1/2)+\delta-\epsilon}} \ll K^{-(1/2)+\delta(2-\sigma)}. \tag{4.33}
\]
By taking \( \delta \) sufficiently large, we can make this sum as small as we desire (and thus smaller than the contribution from the averaged \( S_1(\phi) \)). \qed

**Remark 4.9.** There is a mistake right before equation (8.10) in [23]; it should read
\[
4I'(x) = \frac{2}{K} h'( \frac{x + \eta}{K} ) + O \left( \frac{x}{K^2} \right), \quad \eta \in (-1, 1); \tag{4.34}
\]

fortunately all Iwaniec, Luo and Sarnak [23] used in their argument is that \( I'(x) \ll K^{-1} \) when \( x \ll K^{2-\epsilon} \), and that is true. Also, it is worth noting that our analysis of \( Q^{(2)} \) uses their results for the family \( \{ \text{sym}^2 f : f \in H^*_N(N) \} \); our support is significantly larger because: (1) this is now a \( 1/p \) term and not a \( 1/\sqrt{p} \); (2) we sum over \( p \leq R^{\sigma/2} \) and not \( p \leq R \).

4.3. **Hypothesis S and further extensions.**

Iwaniec, Luo and Sarnak [23] showed how a hypothesis on the size of some classical exponential sums over the primes can be used to increase the support to beyond \((-2, 2)\). They considered
Hypothesis S: For any $x \geq 1$, $c \geq 1$ and $a$ with $(a,c) = 1$ we have
\[
\sum_{\substack{p \leq x \\ p \equiv a \mod{c}}} \exp \left( \frac{4\pi i \sqrt{p}}{c} \right) \ll \epsilon \exp \left( cA x^{\alpha + \epsilon} \right),
\] (4.35)
where $\alpha$, $A$ are constants with $A \geq 0$, $1/2 \leq \alpha \leq 3/4$ and $\epsilon$ is any positive number.

They presented numerous arguments (see their Section 10 and their Appendix C) in support of the belief that Hypothesis S holds with $A = 0$ and $\alpha = 1/2$; however, any $\alpha < 3/4$ suffices to increase the support past $(-2, 2)$. (Vinogradov proved Hypothesis S with $\alpha = 7/8$; assuming the standard density hypothesis for Dirichlet $L$-functions allows one to take $\alpha = 3/4$.) We show how this hypothesis allows us to extend our computations. As Iwaniec, Luo and Sarnak [23] were only concerned with the main term, their error bounds are too crude; however, some additional book-keeping suffices to obtain all lower-order terms up to a power savings in the family’s cardinality.

To prove the third statement in Theorem 1.6 we need to study the weighted averages over $k$ of $S_i(\phi)$ ($i \in \{1, 2, 3\}$). We note that they use the Petersson weights in their Section 10 (and thus we are using the same normalization for our sums). From Lemma 4.4, we see that we may average $S_2(\phi)$ and obtain a contribution bounded by $O(K^{-(5 - \sigma)/6 + \epsilon})$. The analysis in [23, Section 10] handles $S_1(\phi)$, and shows (under the assumption that Hypothesis S holds) that it is $O(K^{-(2(2.5 - \sigma)) + 5(2A + 11/2 + \epsilon)(1 - (2\alpha + A + 5/4)/(2A + 11/2 + \epsilon))})$. In particular, taking $A = 0$ and $\alpha = 1/2$ yields that the weighted average of $S_1(\phi)$ is $O(K^{-2(2.5 - \sigma)} + K^{-(11/2 - 0.232)})$.

We are left with bounding the weighted average over $k$ of $S_2(\phi)$, remembering $R = K^2$. In [23] it was shown to be $O(\log \log K / \log K)$, which does not suffice for our purposes. This term contributes
\[
\frac{1}{B(K)} \sum_{p \leq R^{\sigma/2}} B(p^2, 1) \hat{\phi} \left( \frac{2 \log p}{\log R} \right) \frac{\log p}{p \log R},
\] (4.36)
where $B(K) = \hat{h}(0) K + O(1)$ (with $\hat{h}(0) \neq 0$),
\[
B(p^2, 1) = \frac{-\sqrt{\pi K}}{\sqrt{p}} \Im \left\{ \frac{1}{8} \sum_{c} \frac{S(1, p^2, c)}{c} e^{4\pi ip/c} e^{cK^2/8\pi p} \right\} + O(\sqrt{p} K^{-4})
\] (4.37)
and $\hat{h}(v) \ll v^{-\delta}$ for any $\delta > 0$. The $O(pK^{-4})$ term in $B(p^2, 1)$ leads to a contribution of size $K^{-(5 - \sigma)}$, which is dwarfed by the other error terms. We trivially bound the main term in $B(p^2, 1)$ by using $S(1, p^2, c) \ll c^{(1/2) + \epsilon}$ and $h(cK^2/8\pi p) \ll p^{\delta}/(cK^2)\delta$ for some $\delta > 1/2$ (we take $\delta > 1/2$ so that the resulting $c$-sum converges). This yields a contribution to the average of $S_2(\phi)$ of
\[
\frac{1}{K} \sum_{p \leq R^{\sigma/2}} \frac{K}{\sqrt{p}} \sum_{c} \frac{c^{(1/2) + \epsilon}}{c} \frac{p^{\delta}}{cK^{2\delta}} \frac{1}{p} \ll K^{-2\delta} \sum_{p} p^{\delta - (1/2) - 1} \ll K^{(\delta - (1/2))\sigma - 2\delta}.
\] (4.38)
Taking $\delta$ just a little larger than $1/2$ shows that this error is also dwarfed by our existing errors (as well as being $O(N^{-1+\epsilon})$, which completes the proof.

5. Calculating the unweighted 1-level density

Much effort was spent removing the harmonic weights in [23]. Below we remove them for our family and calculate the lower-order terms. We see some new, lower-order terms that did not appear in either the expansion from the Ratios conjecture or our number theory computations. This is not entirely surprising, as those computations were for weighted sums.

We prove Theorem 1.9. We first concentrate on the unweighted version of $S_1(\phi)$, which yields negligible contributions for $\sigma < 2$. We then analyze the unweighted versions of $S_2(\phi)$ and
5.1. Analyzing the unweighted $S_1(\phi)$

Below we modify the arguments in [23] to show that $S_{1,\text{unwt}}(\phi)$ has negligible contribution for $\sigma < 2$ when we do not include the harmonic weights.

**Lemma 5.1.** Assume GRH for $L(s, f)$. If $\text{supp}(\hat{\phi}) \subset (-\sigma, \sigma)$ with $\sigma < 2$, then $S_{1,\text{unwt}}(\phi) \ll N^{-(2-\sigma)/6+\epsilon}$ as $N \to \infty$ through the primes, where $S_{1,\text{unwt}}(\phi)$ is defined analogously as $S_1(\phi)$ except that now we do not include the harmonic weights.

**Proof.** We use the expansions in [23] for $\Delta_{k,N}^*(p)$, remembering to divide by $|H_k^*(N)|$. Let $X$ and $Y$ be two arbitrary parameters (depending on $N$) to be determined later. We let $\epsilon$ denote an arbitrarily small number (not necessarily the same value from line to line). We write

$$\Delta_{k,N}^*(p) = \Delta_{k,N}^p(p) + \Delta_{k,N}^\infty(p),$$

(5.1)

where ([23, (2.63)])

$$\Delta_{k,N}^p(p) = \frac{k-1}{12} \sum_{L \leq N} \frac{\mu(L)M}{\nu((n, L))} \sum_{m \leq Y} \frac{\Delta_{k,M}(m^2, n)}{m},$$

(5.2)

and $\Delta_{k,N}^\infty(p)$ is the complementary sum. Here

$$\nu(\ell) = |\Gamma_0(1) : \Gamma_0(\ell)| = \ell \prod_{p\mid \ell} \frac{p+1}{p}.$$  

(5.3)

As $N$ is prime, so long as $X < N$, in $\Delta_{k,N}^p(p)$ the only term is when $L = 1$ and $M = N$. Thus

$$S_{1,\text{unwt}}(\phi) = \frac{1}{|H_k^*(N)|} \sum_{p \parallel N} \Delta_{k,N}^p(p) \hat{\phi} \left( \frac{\log p}{\log R} \right) \left( \frac{2 \log p}{\sqrt{p \log R}} \right),$$

$$+ \frac{1}{|H_k^*(N)|} \sum_{p \parallel N} \Delta_{k,N}^\infty(p) \hat{\phi} \left( \frac{\log p}{\log R} \right) \left( \frac{2 \log p}{\sqrt{p \log R}} \right),$$

$$= S_{1,\text{unwt}}^p(\phi) + S_{1,\text{unwt}}^\infty(\phi).$$

(5.4)

We first show that there is no contribution from the complementary sum. As we are going for a power savings in $N$ and not just attempting to understand the main term, we choose different values for $X$ and $Y$ then in [23], and argue slightly differently. Assuming the Riemann hypothesis for $L(s, f)$, if $\log Q \ll \log kN$ then ([23, Lemma 2.12])

$$\sum_{(p, N) = 1 \atop p < Q} \Delta_{k,N}^\infty(p) \frac{\log p}{\sqrt{p}} \ll kN(pkNY)^\epsilon (X^{-1} + Y^{-1/2}).$$

(5.5)

Using partial summation, the compact support of $\hat{\phi}$ and $H_k^*(N) \ll kN$ shows that the complementary sum piece is bounded by

$$S_{1,\text{unwt}}^\infty(\phi) = \frac{1}{kN \log R} \int_{R^*} \frac{dp}{p \log R} \left| kN(pkNY)^\epsilon (X^{-1} + Y^{-1/2}) \right| \left| \hat{\phi} \left( \frac{\log p}{\log R} \right) \right| \left| \frac{dp}{p \log R} \right| 

\ll N^\epsilon (X^{-1} + Y^{-1/2}).$$

(5.6)
We now analyze the contribution from $\Delta_{k,N}(p)$. The formulas from [23] simplify greatly as we only have one $(L, M)$ pair, and as $p$ is not a perfect square there are no main terms. We have

$$S_{1,\text{unwt}}(\phi) = \frac{(k-1)N}{12|H^*_k(N)|} \sum_{(m,N)=1} \frac{1}{m} \sum_{c \equiv 0 \mod N} \frac{Q^*_k(m;c)}{c},$$

where

$$Q^*_k(m;c) = 2\pi i^k \sum_{p \not\equiv \pm 1} \frac{S(m^2, p; c)}{c} j_{k-1} \left( \frac{4\pi m\sqrt{p}}{c} \right) \hat{\phi} \left( \frac{\log p}{\log R} \right) \frac{2\log p}{\sqrt{p}\log R}.$$  

In [23, (5.14)] the authors set $X = Y = (kN)^s$; however, their estimates of $Q^*_k(m;c)$ are independent of $X$ and $Y$, and we may thus use their results. We have (see [23, (7.1)])

$$Q^*_k(m;c) \ll \tilde{\gamma}(z)mP^{1/2}(kN)^s(\log 2c)^{-2},$$

where $R = k^2N$, $P = R^\sigma$, $z = 4\pi m\sqrt{P}/c$ and $\tilde{\gamma}(z) = 2^{-k}$ if $3z \leq k$ and $k^{-1/2}$ otherwise. Thus

$$S_{1,\text{unwt}}(\phi) \ll \sum_{(m,N)=1} \frac{1}{m} \sum_{c \equiv 0 \mod N} \frac{(k^2N)^{\sigma/2}(kN)^{\sigma}}{c(\log 2c)^2} \ll N^{(\sigma/2)-1+\epsilon}Y.$$  

Combining our estimates yields

$$S_{1,\text{unwt}}(\phi) \ll N^{(\sigma/2)-1+\epsilon}Y + \epsilon^*(X^{-1} + Y^{-1/2}).$$

We may take $X = N - 1$ (as $N$ is prime). Equalizing the two errors involving $Y$, we find that we should take $Y = N^{(2-\sigma)/3}$, which gives $S_{1,\text{unwt}}(\phi) \ll N^{(2-\sigma)/6}$.

**Lemma 5.2.** Assume GRH for $L(s, f)$. If $\text{supp}(\hat{\phi}) \subset (-\sigma, \sigma)$ with $\sigma < 2$, then $S_{1,\text{unwt}}(\phi) \ll K^{-(2-\sigma)/6+\epsilon}$ as $N = 1$ and $K \to \infty$ (where we average over the weights).

**Proof.** As the proof is similar to that of Lemma 5.1, we merely highlight the differences. Following [23, Section 8], we average over the weights as follows. Let $h$ be a Schwartz function compactly supported on $(0, \infty)$. We consider the weighted 1-level density

$$A^*(K; \phi) = \frac{1}{A^*(K)} \sum_{k \equiv 0 \mod 2} \frac{24}{k-1} h \left( \frac{k-1}{K} \right) \sum_{f \in H^*_k(1)} D_{1, H^*_k(1); k^2}(\phi),$$

where

$$A^*(K) = \sum_{k \equiv 0 \mod 2} \frac{24}{k-1} h \left( \frac{k-1}{K} \right) |H^*_k(1)| = \tilde{h}(0)K + O(K^{2/3}).$$

The pieces whose errors cannot be trivially added arise from $S_{1,\text{unwt}}(\phi)$ ($i \in \{1, 2, 3\}$) for each $k$. We analyze the weighted average of $S_1(\phi)$ below, and then study the other two in §5.2. The main idea is to exploit the oscillation in the Bessel functions as $k$ varies.

In [23, Lemma 2.12] we now take $X = 1$ and $Y = K^{\delta}$. The complementary sum gives an error bounded by $k^\epsilon Y^{-1/2}$. The averaging over $k$ allows us to exploit the oscillation in the Bessel functions; this is the reason we are able to double the support. The main input is [23, Corollary 8.2], which says

$$I(x) = \sum_{k \equiv 0 \mod 2} 2^{k} h \left( \frac{k-1}{K} \right) J_{k-1}(x) \ll xK^{-4},$$

where $x = 4\pi m\sqrt{P}/c$ and $P = R^\sigma = K^{2\sigma}$. Corollary 8.2 requires $x \ll K^{2-\epsilon}$. In their arguments Iwaniec et al. take $Y = K^\epsilon$, and thus for them $m \ll K^\epsilon$ (recall $m \ll Y$). As we are interested in
sharper error estimates, we must take $Y$ a small power of $K$. This leads to a slight reduction in the support (our condition on $x$ forces $\sigma < 2 - \delta$). The proof is completed by feeding in the estimate from their equation (8.11), which yields a bound of $K^{\sigma+\delta+\epsilon-2}$ for the term from the non-complementary piece (remember we already executed the summation over $k$ when we bounded $I(x)$).

Thus the total error from the sum over $k$ of the $S_{1, \text{unwt}}(\phi)$ terms is $O(K^{\sigma}Y^{-1/2} + K^{\sigma+\delta+\epsilon-2})$. Equalizing the errors yields $\delta = (2 - \sigma)/3$, or the total error from the weighted $S_{1, \text{unwt}}(\phi)$ terms is $O(K^{-(2-\sigma)/6})$.

Remark 5.3. There is a mistake right before [23, equation (8.10)]; see Remark 4.9.

5.2. Analyzing the unweighted $S_2(\phi)$ and $S_3(\phi)$

We now modify our investigation of $S_2(\phi)$ and $S_3(\phi)$ and remove the weights. We set

$$S_{3, \text{unwt}}(\phi) = \frac{2}{|H^\ast(N)|} \sum_{f \in H^\ast(N)} \sum_{p \not\equiv N} \sum_{v=3}^{\infty} \frac{\lambda_f(p^v) - \lambda_f(p^{v-2})}{p^{v/2}} \hat{\varphi} \left( \nu \frac{\log p}{\log R} \right) \frac{\log p}{\log R},$$

$$S_{2, \text{unwt}}(\phi) = \frac{2}{|H^\ast(N)|} \sum_{f \in H^\ast(N)} \sum_{p \not\equiv N} \frac{\lambda_f(p^2)}{p} \hat{\varphi} \left( 2 \frac{\log p}{\log R} \right) \frac{\log p}{\log R}. \quad (5.15)$$

We argue as in the analysis of $S_{1, \text{unwt}}(\phi)$. As the two terms are handled analogously, we concentrate on $S_{3, \text{unwt}}(\phi)$. The analysis is significantly easier than the analysis of $S_{1, \text{unwt}}(\phi)$ due to the higher power of primes (both in dividing by larger quantities and restricting further the summation over primes). Let $v = \nu$ or $v = \nu - 2$. We must study the pure sums

$$\Delta^\ast_{k,N}(p^v) = \sum_{f \in H^\ast(N)} \lambda_f(p^v). \quad (5.16)$$

From [23, Proposition 2.13] we have

$$\Delta^\ast_{k,N}(n) = \frac{(k-1)\varphi(N)}{12\sqrt{n}} \delta_{n,\square} + O \left( \frac{(kN)^{2/3}n^{1/6}}{\sqrt{(n,N)}} \right), \quad (5.17)$$

where the main term is present only if $n$ is a square and $(n, N) = 1$. The contribution from the error term to $S_{3, \text{unwt}}(\phi)$ is bounded by

$$\sum_{\nu \leq \log_2 R} \sum_{p \leq R^{2/3}} \frac{p^{3/2} (kN)^{2/3}}{kN} \leq \frac{\log^2 R}{(kN)^{1/3}}. \quad (5.18)$$

Thus the error term yields a negligible contribution.

The main term from Proposition 2.13, however, is a different story. Whenever $\nu$ is even it will contribute, and yields

$$\sum_{\nu \equiv 0 \mod 2} \sum_{p \not\equiv N} \frac{1 - p}{p^\nu} \hat{\varphi} \left( \nu \frac{\log p}{\log R} \right) \frac{\log p}{\log R}. \quad (5.19)$$

The unweighted $S_2(\phi)$ term will also contribute, as it involves $\lambda_f(p^2)$. It gives another secondary term of size $1/\log R$, as well as an error of size $O(N^{-(6-\sigma)/6+\epsilon})$. Substituting everything into
\begin{equation}
D_{1,H_k^*(N);R}(\phi) = \frac{1}{\log R} \int_{-\infty}^{\infty} \left( 2 \log \frac{\sqrt{N}}{\pi} + \psi \left( \frac{1}{4} + \frac{k \pm 1}{4} + \frac{2\pi it}{\log R} \right) \right) \phi(t) \, dt
+ 2 \sum_{\nu \equiv 0 \mod 2 \atop \nu \geq 2} \sum_{p \neq N} \frac{p - 1}{p^{\nu} \phi} \left( \frac{\log p}{\log R} \right) \log p
+ O \left( N^{-1/2} + N^{-(2-\sigma)/6+\epsilon} \right);
\tag{5.20}
\end{equation}

the sum starts at \( \nu = 2 \) and not \( \nu = 4 \) as we have incorporated both \( S_2, \text{unwt}(\phi) \) and the \( \sum_{p \leq R} 1/p \) term in \eqref{4.4}. This completes the analysis of the number theory terms in Theorem 1.9.

5.3. Unweighted ratios prediction

We sketch the derivation of the prediction for the unweighted 1-level density from the Ratios conjecture, which completes the proof of Theorem 1.9. We concentrate on the case \( N \to \infty \) through the primes. As the analysis is similar to the weighted case, we just highlight the new terms.

The Ratios conjecture recipe states that we should replace averages over the family by the average over the family by using \eqref{5.17}; which says that there is no main term unless we are \( O(1) \).

We now average over the family and divide by the family’s cardinality; this replaces \( \lambda_f(p)^n \) with \( 1/p^n \) (remember we ignore all error terms). Using the geometric series formula and completing

\begin{equation}
\prod_{p} \left( 1 - \frac{1}{p^{1+\alpha+\gamma}} + \frac{1}{p^{1+2\gamma}} \right);
\tag{5.21}
\end{equation}

now, however, we shall see it is

\begin{equation}
\prod_{p} \left( 1 - \frac{p+1}{p} \frac{1}{p^{1+\alpha+\gamma}} + \frac{1}{p^{1+2\gamma}} \right) \cdot \left( 1 - \frac{1}{p^{2+2\alpha}} \right)^{-1}.
\tag{5.22}
\end{equation}

We do not worry about the changes to the second term, as it leads to a contribution of size \( O(1/N) \).

The proof follows from mirroring the calculation in Lemma 2.6. We again split the sum into a product over primes. We constantly use (from \eqref{4.3}) \( \lambda_f(p)\lambda_f(p^{\nu}) = \lambda_f(p^{\nu-1}) + \lambda_f(p^{\nu+1}) \). We average over the family by using \eqref{5.17}; which says that there is no main term unless we are evaluating at a square. Thus below we drop all terms involving \( \lambda_f(p)\lambda_f(p^{2k}) \) or \( \lambda_f(p^{2k+1}) \), as these yield lower-order terms. We also ignore the product over \( p \geq x \), as those terms vanish when we complete the product by sending \( x \to \infty \). Thus we have that

\begin{equation}
\sum_{m \leq x} \frac{\mu_f(h)\lambda_f(m)}{h^{(1/2)+\gamma}m^{(1/2)+\alpha}} = \prod_{p \leq x} \left( 1 - \frac{\lambda_f(p)}{p^{(1/2)+\gamma}} + \frac{1}{p^{1+2\gamma}} \right) \cdot \left( 1 + \frac{\lambda_f(p)}{p^{(1/2)+\alpha}} + \frac{\lambda_f(p^2)}{p^{1+2\alpha}} + \ldots \right)
\tag{5.23}
\end{equation}

contributes

\begin{equation}
\prod_{p \leq x} \left[ \left( 1 + \frac{1}{p^{1+2\gamma}} \right) \sum_{k=0}^{\infty} \frac{\lambda_f(p^{2k})}{(p^{1+2\alpha})^k} - \frac{1}{p^{1+\alpha+\gamma}} \sum_{k=0}^{\infty} \frac{\lambda_f(p^{2k})}{(p^{1+2\alpha})^k} \right].
\tag{5.24}
\end{equation}

We now average over the family and divide by the family’s cardinality; this replaces \( \lambda_f(p^{2\ell}) \) with \( 1/p^{\ell} \) (remember we ignore all error terms). Using the geometric series formula and completing
the product, after some simple algebra we find a contribution of
\[
\prod_p \left( 1 + \frac{1}{p^{1+2\gamma}} - \frac{p+1}{p} \frac{1}{p^{1+\alpha+\gamma}} \right) \left( 1 + \frac{1}{p^{2+2\alpha}} \right)^{-1}.
\] (5.25)

For the Ratios conjecture prediction, however, we need the derivative of this piece with respect to \(\alpha\) when \(\alpha = \gamma = r\). We must therefore modify Lemma 2.9 as well. This piece contributes to \(R_H^{r_k(N)}(r, r)\) a factor of
\[
\sum_p \frac{(p-1) \log p}{p^{1+2r}} = \sum_p \frac{(p-1) \log p}{p^{2k+2r}};
\] (5.26)
this is very similar to what we previously had for \(R_H^{r_k(N)}(r, r)\), namely
\[
\sum_p \log p \frac{p}{p^{1+2r}}.
\] (5.27)

This change propagates to Lemma 3.1, where instead of
\[
\int_{-\infty}^\infty g(t) \sum_p \log p \frac{p}{p^{1+2it}} dt = \sum_p \hat{g} \left( \frac{2 \log p}{2\pi} \right)
\] (5.28)
we now have
\[
\int_{-\infty}^\infty g(t) \sum_p \frac{(p-1) \log p}{p^{2k+2it}} dt = \sum_p \hat{g} \left( \frac{2k \log p}{2\pi} \right).
\] (5.29)

Setting \(g(t) = \phi(t \log R/2\pi)\) and collecting all the terms completes the proof of the Ratios conjecture’s prediction in Theorem 1.9.

\section*{Appendix A. Petersson formula}
Below we record several useful variants of the Petersson formula. We define
\[
\Delta_{k,N}(m,n) = \sum_{f \in B_k(N)} \omega_f(N) \lambda_f(m) \lambda_f(n).
\] (A.1)
We quote the following versions of the Petersson formula from [23] (to match notation, note that \(\sqrt{\omega_f(N)} \lambda_f(n) = \psi_f(n)\)).

\begin{lemma} [[[23, Proposition 2.1]]] \label{lem:petersson}
We have
\[
\Delta_{k,N}(m,n) = \delta(m,n) + 2\pi i^k \sum_{c \equiv 0 \mod N} \frac{S(m,n;c)}{c} J_{k-1} \left( \frac{4\pi \sqrt{mn}}{c} \right),
\] (A.2)
where \(\delta(m,n)\) is the Kronecker symbol,
\[
S(m,n;c) = \sum_{d \mod c}^* \exp \left( 2\pi i \frac{md + nd}{c} \right)
\] (A.3)
is the classical Kloosterman sum \((dd \equiv 1 \mod c)\), and \(J_{k-1}(x)\) is a Bessel function.
We expect the main term to arise only in the case when $m = n$ (though as shown in [19, 23], the non-diagonal terms require a sophisticated analysis for test functions with sufficiently large support). We have the following estimates.

**Lemma A.2** ([23, Corollary 2.2]). We have
\[
\Delta_{k,N}(m,n) = \delta(m,n) + O\left(\frac{\tau(N) (m,n,N)\tau_3((m,n))}{N^{k^2/6}} \left(\frac{mn}{\sqrt{mn+kN}}\right)^{1/2} \log 2mn\right),
\]
(A.4)
where $\tau_3(\ell)$ denotes the corresponding divisor function (which is the sum of the cubes of the divisors of $\ell$).

We can significantly decrease the error term if $m$ and $n$ are small relative to $kN$.

**Lemma A.3** ([23, Corollary 2.3]). If $12\pi \sqrt{mn} \leq kN$ we have
\[
\Delta_{k,N}(m,n) = \delta(m,n) + O\left(\frac{\tau(N) \tau_3((m,n))}{2^k N^{3/2}} \sqrt{mn} \log mn + \tau(N)^{1/2} \log 2mn\right),
\]
(A.5)

In this paper we consider two cases, $N = 1$ and $k \to \infty$ or $k$ fixed and $N \to \infty$ through prime values. In the first case, there is no problem with using the above formulas; however, in the second case we must be careful. Here $\Delta_{k,N}(m,n)$ is defined as a sum over all cusp forms of weight $k$ and level $N$; in practice we often study the families $H_k^\pm(N)$ of cuspidal newforms of weight $k$ and level $N$ (if $\sigma = +$ we mean the subset with even functional equation, if $\sigma = -$ we mean the subset with odd functional equation, and if $\sigma = \ast$ we mean all). Thus we should remove the contribution from the oldforms in our Petersson expansions. Fortunately this is quite easy if $N$ is prime, as then the only oldforms are those of level 1 (following [23], with additional work we should be able to handle $N$ square-free, though at the cost of worse error terms). We have (see [23, (1.16)])
\[
|H_k^\pm(N)| \sim \frac{k - 1}{24} \varphi(N),
\]
(A.6)
where $\varphi(N)$ is Euler’s totient function (and thus equals $N - 1$ for $N$ prime). The number of cusp forms of weight $k$ and level 1 is (see [23, (1.15)]) approximately $k/12$. As $\lambda_f(n) \ll \tau(n) \ll n^\epsilon$ and $\omega_f(N) \ll N^{-1+\epsilon}$, we immediately deduce the following result.

**Lemma A.4.** Let $B_k^\text{new}(N)$ be a basis for $H_k^\ast(N)$ and let $\omega_f(N)$ be as in (1.13). For $N$ prime, we have
\[
\sum_{f \in B_k^\text{new}(N)} \omega_f^\ast(N)\lambda_f(m)\lambda_f(n) = \Delta_{k,N}(m,n) + O\left(\frac{(mn)^\epsilon k}{N}\right).
\]
(A.7)
Substituting yields
\[
\sum_{f \in B_k^\text{new}(N)} \omega_f^\ast(N)\lambda_f(m)\lambda_f(n) = \delta(m,n) + O\left(\frac{(mn)^\epsilon k}{N}\right) + O\left(\frac{\tau(N) (m,n,N)\tau_3((m,n))}{N^{k^2/6}} \left(\frac{mn}{\sqrt{mn+kN}}\right)^{1/2} \log 2mn\right),
\]
(A.8)
factors, when we shift contours, and we want to avoid the pole of the numerator. The ratio of the Gamma factors is
\[ \frac{\Gamma((2k-1)/3)}{\Gamma((2k-1)/3 + \pi it/\log R)} \leq \frac{1}{\Gamma((2k-1)/6)} \int_0^1 (t \cdot (1-t))^{(2k-1)/6-1} \, dt \leq \frac{4}{\Gamma((2k-1)/6)} \, \frac{1}{\Gamma((2k-1)/6)} \]
(as the integrand is largest when \( t = 1/2 \)). Thus for \( w = (2k-1)/3 \), applying Stirling’s formula to \( \Gamma((2k-1)/6) \) we find
\[ \left| X_L \left( \frac{k+1}{3} + \frac{2\pi it}{\log R} \right) \right| \leq \left( \frac{\pi}{\sqrt{N}} \right)^{(2k-1)/3} \cdot \frac{4}{\Gamma((2k-1)/6)} \leq \left( \frac{2009}{\sqrt{N}} \right)^{(2k-1)/3} \cdot k^{-k/3}. \]
\[ \]
of $R_{\sigma w} = k^{2\sigma w}$ from $\hat{\phi}$ from the contour shift (see (3.27)). This forced us to take $\sigma < 1/4$, as our denominator was (essentially) $k^{w/2}$. We sketch an alternative approach using Hölder’s inequality; unfortunately this method also forces $\sigma < 1/4$ (and gives a worse error term).

We apply (B.2) with $a = (1 - w)/4 + (k - 1)/2$ and $b - a = w/2$. We choose $w = 1/8$ for definiteness and ease of exposition; similar results hold for all $w$, always requiring $\sigma < 1/4$. For such $w$, we have $b - a - 1 < 0$; thus the factor of $(1 - t)^{b-a-1}$ is very large for $t$ near 1. We surmount this by using Hölder’s inequality, which states that if $p, q \geq 1$ with $1/p + 1/q = 1$ then

$$\int_0^1 |f(t)g(t)| dt \leq \left( \int_0^1 |f(t)|^p dt \right)^{1/p} \cdot \left( \int_0^1 |g(t)|^q dt \right)^{1/q}. \quad (B.5)$$

We let $f(t) = t^{a-1}$, $g(t) = (1 - t)^{b-a-1}$, $p = 16/(1 - 16\epsilon)$ and $q = 16/(15 + 16\epsilon)$ in Hölder’s inequality, yielding

$$\int_0^1 t^{a-1}(1 - t)^{b-a-1} dt \leq \left( \int_0^1 t^{(a-1)p} dt \right)^{1/p} \cdot \left( \int_0^1 (1 - t)^{(b-a-1)q} dt \right)^{1/q}. \quad (B.6)$$

As $(b - a - 1)q = -15/(15 + 16\epsilon) < -1$, the integral involving $1 - t$ is just $O(1)$. The integral involving $t$ is $((a - 1)p + 1)^{-1/p} \ll k^{-1/16+\epsilon}$. For $\sigma < 1/4$, the $k^{2\sigma w}$ term from (3.27) will be smaller than $k^{1/16}$.

**Lemma B.3.** Let $\phi$ be an even Schwartz function such that $\text{supp}(\hat{\phi}) \subset (-\sigma, \sigma)$. Then

$$\phi(t + iy) \ll_n \phi e^{2\pi y^2} \cdot (t^2 + y^2)^{-n}. \quad (B.7)$$

**Proof.** From the Fourier inversion formula, integrating by parts and the compact support of $\hat{\phi}$, we have

$$\phi(t + iy) = \int_{-\infty}^{\infty} \hat{\phi}(\xi) e^{2\pi i(t+iy)\xi} d\xi$$

$$= \int_{-\infty}^{\infty} \hat{\phi}^{(2n)}(\xi) \cdot (2\pi i(t + iy))^{-2n} e^{2\pi i(t-i\xi)} d\xi$$

$$\ll e^{2\pi |y|\sigma} (t^2 + y^2)^{-n}. \quad (B.8)$$

**Lemma B.4.** Let

$$A(x + iy) = \prod_p \left( 1 - \frac{p^{x+iy} - 1}{p(p^{1+x+iy} + 1)} \right). \quad (B.9)$$

If $x > -1$ then $A(x + iy) = O(1)$.

**Proof.** We have

$$|A(x + iy)| \leq \prod_p \left( 1 + \frac{2\max(1, p^{x})}{p^{2+x}} \right), \quad (B.10)$$

and the product is $O(1)$ as long as $x > -1$. 

\qed
Appendix C. Mertens’s theorem and how we extend the sums

We examine other ways of completing the product of the second factor in the definition of \( R_{H^2(N)}(\alpha, \gamma) \), and the consequences of this alternate completion on \( R_{H^2(N)}(r, r) \). Recall that this second factor contributes the product

\[
\prod_{p \leq y} \left(1 - \frac{1}{p^{1-\alpha+y}}\right) \cdot \left(1 + \frac{p^{1-\alpha+\gamma}}{p^{1+2\gamma}(p^{1-\alpha+\gamma} - 1)}\right) \cdot \prod_{p > y} \left(1 + \frac{1}{p^{1+2\gamma}}\right); \tag{C.1}
\]

we wrote it this way as we wanted to pull out factors of \( 1/\zeta(1 - \alpha + \gamma) \) before sending \( y \to \infty \). We now analyze this contribution in another manner. We do not pull out the factors of \( 1/\zeta(1 - \alpha + \gamma) \), and we keep \( y \) fixed and finite. To find the derivative with respect to \( \alpha \) forces us to analyze the following (we ignore the product over \( p > y \) for now as these terms have no \( \alpha \) dependence):

\[
\prod_{p \leq y} \left(1 - \frac{1}{p^{1-\alpha+\gamma}} + \frac{1}{p^{1+2\gamma}}\right); \tag{C.2}
\]

here the product over \( p \leq y \) follows from brute force multiplication of the two terms in (C.1). Keeping \( y \) fixed, we now calculate the derivative of (C.2) with respect to \( \alpha \):

\[
\frac{\partial}{\partial \alpha} \left[ \prod_{p \leq y} \left(1 - \frac{1}{p^{1-\alpha+\gamma}} + \frac{1}{p^{1+2\gamma}}\right) \right] \bigg|_{\alpha = \gamma = r} = \prod_{p \leq y} \left(1 - \frac{1}{p^{1-\alpha+\gamma}} + \frac{1}{p^{1+2\gamma}}\right) \cdot \sum_{q \leq y} \left(1 - \frac{1}{q} + \frac{1}{q^{1+2r}}\right)^{-1} \cdot -\log q. \quad (C.3)
\]

It is here that we must be careful in how we complete the sums (that is, in how we let \( y \to \infty \)). For \( \Re(r) > 0 \) we write

\[
\prod_{p \leq y} \left(1 - \frac{1}{p} + \frac{1}{p^{1+2r}}\right) = \prod_{p \leq y} \left(1 - \frac{1}{p}\right) \cdot \prod_{p \leq y} \left(1 + \frac{1}{(p-1)p^{2r}}\right); \tag{C.4}
\]

as \( \Re(r) > 0 \), the second factor is of size 1. By Mertens’s Theorem (see [7]) we have

\[
\prod_{p \leq y} \left(1 - \frac{1}{p}\right) = \frac{e^{-\gamma}}{\log y} \left(1 + O\left(\frac{1}{\log y}\right)\right). \tag{C.5}
\]

Thus this product over primes tries to make our resulting term small; it is, however, balanced by the sum over \( q \) of \( \log q/q \), as (see [7])

\[
\sum_{q \leq y} \frac{\log q}{q} \sim \log y + O(1). \tag{C.6}
\]

Completing the book-keeping, we find a very similar result for the second term in Lemma 2.9. Sending \( y \to \infty \) gives us the second term in Lemma 2.9, but now multiplied by \( e^{-\gamma} \).

This is a fascinating observation. It shows that there are at least two natural answers, and their main terms differ by \( e^{-\gamma} \). Which is correct? It will almost surely be impossible to tell as \( N \to \infty \), as this term contributes \( O(1/N) \), and thus is well beyond current technology! We hope in a future paper to explore the case where \( N = 1 \) and \( k \to \infty \) further.

Moreover, there is much number theory and probability theory in \( e^{-\gamma} \). Instead of the prime numbers, one could instead look at ‘random’ primes. There are many different models one can use to generate sequences of ‘random’ primes; often for each integer \( n \) one sets \( n \) to be
prime with probability \(p(n)\) (with \(p(n)\) chosen so that the density of our sequence mimics that of the primes). In these cases, the Riemann hypothesis is true with probability one; however, now the Riemann hypothesis is the statement that \(\pi_{\text{random}}(x) = \text{Li}(x) + O(x^{1/2+\epsilon})\) (and not a statement about zeros of a corresponding function), where \(\pi_{\text{random}}(x)\) denotes the number of ‘random’ primes less than \(x\). In sieving heuristics, the number of primes at most \(x\) is about \(2e^{-\gamma}x/\log x\), where \(2e^{-\gamma} \approx 1.12292\). It is fascinating that the difference is equivalent to the differences in viewing the primes as random independent events versus including the congruence relations! See [1, 13, 15, 16, 34, 43] for additional remarks on \(e^{-\gamma}\).

Acknowledgements. We thank Eduardo Dueñez, David Farmer, Duc Khiem Huynh, Jon Keating and Nina Snaith for many enlightening conversations, and the referee for a very careful reading of the manuscript and many useful comments. Some of this work was carried out while the author was visiting the University of Bristol, and it is a pleasure to thank them for their hospitality.
