SUMMARY This paper concerns cancel minimal linear grammars ([5]) that was introduced to generalize Geffert normal forms for phrase structure grammars. We consider the generative power of restricted cancel minimal linear grammars: the grammars have only one nonterminal symbol C except the start symbol S, and their productions consist of context-free type productions, the left-hand side of which is S and the right-hand side contains at most one occurrence of S, and a unique cancellation production $C^m \rightarrow \epsilon$ that replaces the string $C^m$ by the empty string $\epsilon$. We show that, for any given positive integer $m$, the class of languages generated by cancel minimal linear grammars with $C^m \rightarrow \epsilon$ is properly included in the class of linear languages. Conversely, we show that for any linear language $L$, there exists some positive integer $m$ such that a cancel minimal linear grammar with $C^m \rightarrow \epsilon$ generates $L$. We also show how the generative power of cancel minimal linear grammars with a unique cancellation production $C^m \rightarrow \epsilon$ vary according to changes of $m$ and restrictions imposed on occurrences of terminal symbols in the right-hand side of productions.

key words: minimal linear languages, linear languages, Geffert normal forms, generative power

1. Introduction

Among the variety of normal forms for phrase structure (or type-0) grammars ([1], [3], [7]), Geffert normal forms [1] are unique in the sense that each of them has two different kinds of productions: context-free type productions with only the start symbol S on the left-hand side, and the one or two cancellation productions that replace a sequence of nonterminal symbols except S with the empty string $\epsilon$. The cancellation productions in each Geffert normal form play a vital role to generate any recursively enumerable languages. Furthermore, the cancellation productions are related to cutting operations of DNA strands, and Geffert normal forms are used to examine the generative power of DNA computing models ([6], [8]). Each Geffert normal form also provides an “intermediate grammar” that can bridge a gap between context-free and recursively enumerable languages ([2], [4], [9]).

Onodera [5] gives a framework in which each Geffert normal form is uniformly described as a grammar referred to as a cancel minimal linear grammar. A cancel minimal linear grammar has two kinds of productions: context-free type productions, the left-hand side of which is the start symbol S and the right-hand side contains at most one occurrence of S, and cancellation productions similarly defined as the case of Geffert normal forms. Note that, if we regard each nonterminal symbol except S as a terminal symbol, then the context-free type productions above are considered to be minimal linear, and hence we call the context-free type productions minimal linear type productions in this paper. Within the framework of cancel minimal linear grammars, one of the Geffert's results ([11]) means that the cancel minimal linear grammar with only two cancellation productions $AB \rightarrow \epsilon$ and $CC \rightarrow \epsilon$ has the power of generating any recursively enumerable language.

Onodera [5] examines the generative power of the cancel minimal linear grammars with only one of the two above cancellation productions, under the assumption of dealing with only $\epsilon$-free languages. She shows that the language generated by any cancel minimal linear grammar with $AB \rightarrow \epsilon$ is context-free, and that any linear language can be generated by such a grammar. Furthermore, she shows that the class of languages generated by the cancel minimal linear grammars with $CC \rightarrow \epsilon$ is a proper subset of the class of linear languages.

In this paper, we study the generative power of cancel minimal linear grammars with $C^m \rightarrow \epsilon$ for an arbitrarily fixed $m \geq 1$ without assuming that only $\epsilon$-free languages are allowed. We show that for any given $m \geq 1$, cancel minimal linear grammars with $C^m \rightarrow \epsilon$ only generate linear languages. In contrast to this, for $C^m \rightarrow \epsilon$ with $m$ not bounded, we show that the class of languages generated by those grammars is equivalent to the class of linear languages. We also examine the difference in the generative power of the cancel minimal linear grammars between with $C^m \rightarrow \epsilon$ and with $C^n \rightarrow \epsilon$ for $m \neq n$.

We impose some restrictions on occurrences of terminal symbols in the minimal linear type productions, and show how the restrictions affect the generative power of the cancel minimal linear grammars with $C^m \rightarrow \epsilon$.

These results may shed some new light on relations of language classes between minimal linear languages and linear languages.

2. Preliminaries

We assume the reader to be familiar with the rudiments of formal language theory (see, e.g., Rozenberg and Salomaa [7]).

A phrase structure grammar (a grammar for short) is a construct $G = (N, T, P, S)$, where $N$ is a set of nonterminal
symbols, \( T \) is a set of terminal symbols, \( P \) is a set of productions, and \( S \) in \( N \) is the start symbol. A production in \( P \) is of the form \( \pi_1 \to \pi_2 \), where \( \pi_1 \in (N \cup T)^*N(N \cup T)^* \) and \( \pi_2 \in (N \cup T)^* \). For any \( \alpha_1 \) and \( \alpha_2 \) in \( (N \cup T)^* \), if \( \alpha_1 = \alpha_1 \pi_1 \alpha_2, \alpha_2 = \alpha_1 \pi_2 \alpha_2 \) and \( r : \pi_1 \to \pi_2 \in P \), then we say that \( \alpha_2 \) is derivable from \( \alpha_1 \) by \( r \), and write \( \alpha_1 \Rightarrow_r \alpha_2 \). If \( G \) is understood, we write \( \alpha_1 \Rightarrow \alpha_2 \). Similarly, for a sequence of productions \( \gamma \), we simply write \( \alpha_1 \Rightarrow \gamma \Rightarrow \alpha_2 \). Further, if there is no need to refer to productions, then we simply write \( \alpha_1 \Rightarrow \alpha_2 \), and we denote the reflexive and transitive closure of \( \Rightarrow \) by \( \Rightarrow^* \). A string in \( (N \cup T)^* \) derivable from the start symbol \( S \) is called a sential form.

We define the language \( L(G) \) generated by a grammar \( G = (N, T, P, S) \) as follows: \( L(G) = \{ z \in T^* | S \Rightarrow^* z \} \). It is well known that the class of languages generated by the phrase structure grammars is equal to the class of recursively enumerable languages.

A language \( L \) is said to be \( \epsilon \)-free, if it contains no empty string \( \epsilon \). In this paper, we mainly deal with \( \epsilon \)-free languages.

A grammar \( G = (N, T, P, S) \) is linear if each production in \( P \) is of the form \( \alpha \to \beta \), where \( \alpha, \beta \in N \) and \( \alpha \) contains at most one nonterminal symbol. A language generated by any linear grammar is also called linear. It is obvious that any linear language can be generated by a linear grammar each of whose productions is of the form \( N_1 \to uN_2, N_1 \to N_2u, \) or \( N_1 \to u, \) where \( N_1, N_2 \in N \) and \( u \in T^* \).

A grammar \( G = (N, T, P, S) \) is right (resp. left) linear if it is linear and every production in \( P \) is of the form \( \alpha \to uN_2 \) or \( N_1 \to uN_2 \) (resp. \( N_1 \to N_2u \) or \( N_1 \to u \)), where \( N_1, N_2 \in N \) and \( u \in T^* \). Any language generated by such a grammar is called right (resp. left) linear. It is well known that the class of right linear languages is equivalent to that of left linear languages, which is also called the class of regular languages.

A grammar \( G = (N, T, P, S) \) is minimal linear if \( N = \{ S \} \) and every production in \( P \) is of the form \( S \to uSv \) or \( S \to u \), where \( u, v \in T^* \). Any language generated by such a grammar is called minimal linear.

Geffert [1] shows the following theorem.

**Theorem 1:** Any recursively enumerable language can be generated by a grammar \( G = (\{ S \} \cup N_C, T, P \cup P_C, S) \) satisfying the following conditions:

1. Every production in \( P \) is of the form \( S \to a_1Sa_2 \) or \( S \to a, \) where \( a_1, a_2, a \in (T \cup N_C)^* \).
2. \( N_C = \{ A, B, C \} \) and \( P_C = \{ AB \to \epsilon, CC \to \epsilon \} \).

Note that Geffert examines the other four cases as variations of Theorem 1:

1. \( N_C = \{ A, B, C, D \}, P_C = \{ AB \to \epsilon, CD \to \epsilon \} \).
2. \( N_C = \{ A, B \}, P_C = \{ AB \to \epsilon, BBB \to \epsilon \} \).
3. \( N_C = \{ A, B \}, P_C = \{ ABBA \to \epsilon \} \).
4. \( N_C = \{ A, B, C \}, P_C = \{ ABC \to \epsilon \} \).

He shows that in each case any recursively enumerable language can be generated by a grammar \( G = (\{ S \} \cup N_C, T, P \cup P_C, S) \).

Generalizing these Geffert normal forms, Onodera [5] introduces a new class of grammars as follows.

**Definition 1:** A grammar \( G = (\{ S \} \cup N_C, T, P, S) \) is an \( \Omega \)-cancel minimal linear grammar (\( \Omega \)-cml grammar for short) if it satisfies the following:

1. \( S \) is the start symbol.
2. \( N_C \) is a finite set of nonterminal symbols except \( S \).
3. \( T \) is a finite set of terminal symbols.
4. \( \Omega \) is a finite set of strings in \( N_C^* \).
5. \( P \) is a finite set of productions and is partitioned into two parts \( P_M \) and \( P_C \) defined as follows:

- \( P_M = \{ S \to a_1Sa_2, S \to a | a_1, a_2, a \in (T \cup N_C)^* \} \).
- \( P_C = \{ \omega \to \epsilon | \omega \in \Omega \} \).

We call a production in \( P_M \) a minimal linear type production (\( mL \)-production for short) and a production in \( P_C \) a cancellation production (\( c \)-production for short).

A language \( L \) is an \( \Omega \)-cancel minimal linear language (\( \Omega \)-cml language for short) if there is an \( \Omega \)-cml grammar \( G \) such that \( L = L(G) \).

For a string \( \alpha \), \( \alpha^R \) represents the reverse of \( \alpha \), and let \( |\alpha|_T \) be the number of terminal symbols in \( \alpha \).

**Definition 2:** If an \( mL \)-production has the right side with no terminal symbol, then the production is called a terminal-free \( mL \)-production, otherwise it is called a terminal \( mL \)-production. If a terminal \( mL \)-production is of one of the forms \( S \to a_1Sa_2, S \to aS, S \to Sa, S \to a, \) where \( |a_1|_T, |a_2|_T, |a|_T > 0 \), then it is called strict terminal \( mL \)-production (\( s \)-terminal \( mL \)-production for short).

An \( \Omega \)-cml grammar \( G \) is called a terminal (resp. strict terminal or \( s \)-terminal for short) \( \Omega \)-cml grammar, if any \( mL \)-production in \( P \) is a terminal (resp. \( s \)-terminal) production. A language \( L \) is called a terminal (resp. \( s \)-terminal) \( \Omega \)-cml language if there is a terminal (resp. \( s \)-terminal) \( \Omega \)-cml grammar that generates \( L \).

When we deal with only \( \epsilon \)-free languages, the classes of linear, minimal linear, \( \Omega \)-cancel minimal linear, and regular languages are denoted by \( LINC, ML, CML, \) and \( REG \), respectively. If we deal with \( \Omega \)-cancel minimal linear languages containing the empty string, then we denote the language class by \( CML^\emptyset \).

Note that terminal \( \Omega \)-cancel minimal linear languages and strict terminal \( \Omega \)-cancel minimal linear languages do not contain the empty string. Let \( r_c \) be the terminal-free \( mL \)-production \( S \to \epsilon \).

**Definition 3:** An \( \Omega \)-cml grammar which has no terminal-free \( mL \)-production except \( r_c \) is called an extended terminal \( \Omega \)-cml grammar and a language \( L \) is called an extended terminal \( \Omega \)-cml language if there is an extended terminal \( \Omega \)-cml grammar that generates \( L \).

The classes of terminal \( \Omega \)-cml, strict terminal \( \Omega \)-cml, and extended terminal \( \Omega \)-cml languages are denoted by \( cCML^\emptyset, st-CML^\emptyset, \) and \( e-CML^\emptyset \), respectively.

Onodera [5] examines the generative power of some classes of \( \{ AB \} \)-cml grammars and \( \{ C^2 \} \)-cml grammars.
Concerning \(\{C^2\}\)-cml grammars, she proves the following theorem.

**Theorem 2:**
1. \(\text{ML} \subset \text{t-CML}_{\{C^2\}} \subset \text{LIN}\)
2. \(\text{REG}\) and \(\text{t-CML}_{\{C^2\}}\) are incomparable.

In this paper, for any positive integer \(m\), we deal with \(\{C^m\}\)-cml grammars.

3. \(\{C^m\}\)-cml Languages

In this section, we consider the generative power of terminal \(\{C^m\}\)-cml grammars. In the case of \(m = 1\), a \(\{C\}\)-cml grammar is context-free, and we can remove the nonterminal symbol \(C\) from the original grammar by the standard technique for eliminating \(\epsilon\)-rules from a context-free grammar. Therefore, the following lemma is obvious.

**Lemma 1:** \(\text{st-CML}_{\{C\}} = \text{t-CML}_{\{C\}} = \text{CML}_{\{C\}} = \text{ML}\).

In the following, we consider the case \(m \geq 2\).

3.1 \(\{C^m\}\)-cml Languages and Terminal \(\{C^m\}\)-cml Languages

In this subsection, for any given integer \(m \geq 2\), we consider the generative power of \(\{C^m\}\)-cml grammars and terminal \(\{C^m\}\)-cml grammars. In particular, we examine influences of terminal-free ml-productions on the generative power.

In every \(\{C^m\}\)-cml grammar \(G = ([S, C], T, P, S)\), we may assume that any ml-production in \(P\) is of one of the six forms

\[
(1) \quad S \to C_iuC^k\overline{S}C^jvC^j, \quad (2) \quad S \to C_iuC^kSC_i, \\
(3) \quad S \to C^iSC^jC_i, \quad (4) \quad S \to C^iC^j, \\
(5) \quad S \to \overline{C}C, \quad (6) \quad S \to C_i,
\]

where \(u, v \in T^*, \exists \leq i, j, k, l < m\).

This is because any ml-production can be transformed into one of the above forms by using the c-production \(r_C : C^m \to \epsilon\), or the ml-production makes no contribution to producing a string in \(T^*\). For example, an ml-production \(S \to C^{m+1}uC^kSC^{2m+1}C^l\) with \(u, v \in T^*\) and \(0 \leq i, j, k, l < m\) is equivalent to \(S \to C^iuC^k\overline{S}C^jC_i\), whereas an ml-production \(S \to uC^iSC_i\) with \(u, v \in T^*\) and \(0 < i < m\) is useless to produce a string in \(T^*\).

Note that when we use a notation \(S \to C^iuC^{m-i}S\) with \(i = 0\), the ml-production is not of the form (2) above, because \(C^m\) is not allowed in the form. Hence, in the following, we regard \(C^m\) as \(\epsilon\) in such cases.

According to the six forms above, we partition the set of ml-productions \(P_M\) into six sets \(P(1), P(2), \ldots, P(6)\) such that for each \(n (1 \leq n \leq 6)\), \(P(n)\) consists of ml-productions in the \(n\)-th form above. For example,

\[
P(1) = \{ r \mid r : S \to C^iuC^k\overline{S}C^jvC^j \text{ in } P \text{ and } u, v \in T^* \}.
\]

Each terminal ml-production in \(P\) is in \(P(1) \cup P(2) \cup P(3) \cup P(4)\), while each terminal-free ml-production in \(P\) is in \(P(5) \cup P(6)\). Hence, we denote \(P(1) \cup P(2) \cup P(3) \cup P(4)\) by \(P(t)\), and \(P(5) \cup P(6) \cup \{ tC \} \) by \(P(tf)\). In the following, we call a production in \(P(tf)\) a terminal-free production.

If we use only productions in \(P(tf)\), we cannot produce strings of terminal symbols except for \(\epsilon\), hence there is a possibility that \(\text{t-CML}_{\{C^m\}}\) may be equal to \(\text{CML}_{\{C^m\}}\). To prove the claim, we define a set of terminal ml-productions derived from a terminal ml-production by using terminal-free productions.

**Definition 4:** Let \(G = ([S, C], T, P, S)\) be a \(\{C^m\}\)-cml grammar. For an ml-production \(r : S \to C^iuC^kSC^jvC^j\) in \(P(1)\), we define the closure of \(r \) under terminal-free productions, denoted by \(cl(r)\), as \(cl(r) = cl_1(r) \cup cl_2(r)\), where

- \(S \to C^iuC^k\overline{S}C^jvC^j\) is in \(cl_1(r)\) if there exists a derivation \(\gamma_1\) such that
  \[(1) \quad S \xrightarrow{\gamma_1} C^iuC^k\overline{S}C^jvC^j,\]
  \[(2) \quad r \text{ occurs only once in } \gamma_1, \text{ and the rest of } \gamma_1 \text{ are productions in } P(tf),\]
  \[(3) \quad 0 \leq i', j', k', l' < m,\]

- \(S \to C^iuC^jvC^j\) is in \(cl_2(r)\) if there exists a derivation \(\gamma_2\) such that
  \[(1) \quad S \xrightarrow{\gamma_2} C^iuC^jvC^j,\]
  \[(2) \quad r \text{ occurs only once in } \gamma_2, \text{ and the rest of } \gamma_2 \text{ are productions in } P(tf),\]
  \[(3) \quad 0 \leq i', j' < m,\]

Similarly, for \(r : S \to C^iuC^kSC^j\) in \(P(2)\) and \(r : S \to C^iuC^jvC^j\) in \(P(3)\), we define \(cl(r)\) as \(cl(r) = cl_1(r) \cup cl_2(r)\), and for \(r : S \to C^iuC^j\) in \(P(4)\), we define \(cl(r)\) as \(cl(r) = cl_2(r)\).

By using \(cl(r)\) with \(r\) in \(P(t)\), we define the closure of \(P(t)\) under terminal-free productions as

\[cl(P(t)) = \bigcup_{r \in P(t)} cl(r).\]

**Lemma 2:** \(cl(P(t))\) is a finite set of terminal ml-productions.

**Proof:** Since each definition of \(cl(r)\) with \(r\) in \(P(t)\) imposes the condition \(0 \leq i', j', k', l' < m\), the number of terminal ml-productions in \(cl(r)\) is finite. Therefore, it follows from the definition of \(cl(P(t))\) that \(cl(P(t))\) is a finite set of terminal ml-productions.

Next, by using the closure \(cl(P(t))\), we construct a terminal \(\{C^m\}\)-cml grammar \(\overline{G}\) from a \(\{C^m\}\)-cml grammar \(G = ([S, C], T, P, S)\) which satisfies that if \(L(G)\) is \(\epsilon\)-free then \(L(\overline{G}) = L(G)\).

**Definition 5:** A terminal \(\{C^m\}\)-cml grammar \(\overline{G} = ([S, C], T, \overline{P}, S)\) is the transformed terminal \(\{C^m\}\)-cml grammar of \(G = ([S, C], T, P, S)\) if \(\overline{P} = cl(P(t)) \cup P_c\).

**Theorem 3:** \(\text{CML}_{\{C^m\}} = \text{t-CML}_{\{C^m\}}\).

**Proof:** It is obvious that \(\text{t-CML}_{\{C^m\}} \subset \text{CML}_{\{C^m\}}\) holds. We will prove the converse by showing that for any \(\{C^m\}\)-cml grammar \(G\), if \(L(G)\) is \(\epsilon\)-free then its transformed terminal \(\{C^m\}\)-cml grammar \(\overline{G}\) generates the same language as \(L(G)\).
The inclusion \(L(\overline{G}) \subseteq L(G)\) is obvious from the definition of the closure of a terminal ml-production under terminal-free productions. In order to prove the converse inclusion, we will show that, for \(0 \leq i, j, i', j' < m\) and \(w \in T^+\), if \(C_iS^jC_i' \overset{\gamma}{\Rightarrow}_G C_{i'}wC_{j'}\) then \(C_iS^jC_i' \overset{\gamma}{\Rightarrow}_G C_{i'}wC_{j'}\) by using the induction on the number \(n\) of terminal ml-productions applied in the derivation \(\gamma\). We note that when \(i = j = i' = j = 0\), the claim implies \(L(G) \subseteq L(\overline{G})\).

Base step, \(n = 1\): Consider a derivation \(\gamma\) such that \(C_iS^jC_i' \overset{\gamma}{\Rightarrow}_G C_{i'}wC_{j'}\), where a terminal ml-production \(r\) in \(P(t)\) occurs only once in \(\gamma\), and the rest of \(\gamma\) are productions in \(P(tf)\). Then, there exists a derivation \(\gamma'\) such that \(S \overset{\gamma'}{\Rightarrow}_G C^p_wC^q\), where \(p = (m + i' - i)\ mod\ m\), \(q = (m + j' - j)\ mod\ m\), \(r\) occurs only once in \(\gamma'\), and the rest of \(\gamma'\) are productions in \(P(tf)\). It follows from the definition of \(c(l(r))\) that \(S \rightarrow C^p_wC^q\) is a member of \(c(l(r))\). Therefore, \(C_iS^jC_i' \overset{\gamma'}{\Rightarrow}_G C_{i'}wC_{j'}\) holds.

Induction step: Assume that \(C_iS^jC_i' \overset{\gamma'}{\Rightarrow}_G C_{i'}wC_{j'}\) and the total number of terminal ml-production occurrences in \(\gamma\) is \(n + 1\). Then, there exists one of the following derivations:

1. \(C_iS^jC_i' \overset{\gamma_1}{\Rightarrow}_G C^p_uC^q_vC^rC^sC^tC^uC^vC^wC^y\),
2. \(C_iS^jC_i' \overset{\gamma_1}{\Rightarrow}_G C^p_uC^q_vC^rC^sC^tC^u\),
3. \(C_iS^jC_i' \overset{\gamma_1}{\Rightarrow}_G C^p_uC^q_vC^rC^sC^t\),

where \(0 \leq k, l < m\), \(\gamma_1\) contains only one terminal ml-production occurrence, and the total number of terminal ml-productions in \(\gamma_1\) is \(n\).

We will show that, in the second case, \(C_iS^jC_i' \overset{\gamma_1}{\Rightarrow}_G C_{i'}wC_{j'}\) holds. Since \(\gamma_1\) is a sequence of productions in \(P(tf)\) except one occurrence of a terminal ml-production \(r\), there exists a derivation \(\gamma'_1\) such that \(S \overset{\gamma'_1}{\Rightarrow} C^p_uC^q_vC^rC^s\), where \(p = (m + i' - i)\ mod\ m\), \(q = (m + l - j)\ mod\ m\), \(r\) occurs only once in \(\gamma'_1\), and \(\gamma'_1\) is the rest of \(\gamma_1\) in productions in \(P(tf)\). From the definitions of \(c(l(r))\) and \(\overline{G}\), \(S \rightarrow C^p_uC^q_vC^rC^s\) is a member of both \(c(l(r))\) and \(\overline{G}\). Therefore, \(C_iS^jC_i' \overset{\gamma_1}{\Rightarrow}_G C_{i'}wC_{j'}\) holds.

On the other hand, it follows from \(C^p_uC^q_vC^rC^s \overset{\gamma_1}{\Rightarrow}_G C^p_uC^q_vC^r\) that there exists a string \(w' \in T^+\) such that \(w = uw'\) and \(C^p_uC^q_vC^r \overset{\gamma_2}{\Rightarrow}_G w'C'\). Then, by the induction hypothesis, \(C^p_uC^q_vC^r \overset{\gamma_2}{\Rightarrow}_G w'C'\) holds. Therefore, there is a derivation \(C_iS^jC_i' \overset{\gamma_2}{\Rightarrow}_G C_{i'}w'C_{j'}\). The proof of the first and the third cases is analogous to the proof of the second case. \(\square\)

**Corollary 1:** CML\(^C^\_{\{\gamma\}}\) = T-CML\(^C^\_{\{\gamma\}}\). Moreover, for any \(\{C^m\}\)-cml grammar \(G\), if \(\epsilon \in L(G)\) then \(L(G) = L(\overline{G}) \cup \{\epsilon\} = L(\overline{G})\), where \(\overline{G} = (\{\gamma\}, C, \overline{T}, \overline{P} \cup \{r_i\}, S)\).

### 3.2 Terminal \(\{C^m\}\)-cml Grammars and Nondeterministic Finite Automata

For any terminal \(\{C^m\}\)-cml grammar \(G\), we construct a nondeterministic finite automaton \(M_G\) such that a derivation step in \(G\) corresponds to a transition in \(M_G\).

In the following, let \(S \rightarrow C^p_uC^q_vC^rC^tC^uC^vC^wC^y\) be an ml-production in \(P(1) \cup P(2) \cup P(3)\) with \(u, v \in T^+\) and \(uv \neq \epsilon\). Then, we assume that if \(u = \epsilon\) then \(k = 0\), and if \(v = \epsilon\) then \(l = 0\).

**Definition 6:** For a terminal \(\{C^m\}\)-cml grammar \(G = ((S, C), T, P, S), M_G = (Q, \Sigma_G, \delta, q_{0,0}, \{q_f\})\) is a nondeterministic finite automaton derived from \(G\), where

\[
\Sigma_G = \{(u[v]) | S \rightarrow C^p_uC^q_vC^rC^tC^uC^vC^wC^y \in P(1) \cup P(2) \cup P(3)\}
\]

and the rest of \(\Sigma_G\). It follows from the definition of \(c(l(r))\) that \(S \rightarrow C^p_uC^q_v\) is a member of \(c(l(r))\). Therefore, \(C_iS^j \overset{\gamma}{\Rightarrow} C_{i'}wC_{j'}\) holds.

We extend \(\delta\) by induction to a function \(\delta^* : Q \times \Sigma_G \rightarrow P(\overline{Q})\) according to the rules:

\[
\delta^*(q, \alpha) = \delta(q, \alpha) \\
\delta^*(q, \alpha \sigma) = \bigcup_{q' \in S^+} \delta(q', \sigma)
\]

where \(\sigma \in \Sigma_G\) and \(\alpha \in \Sigma_G^+\).

Moreover, if \(\alpha = [u_1|v_1]\cdots[u_n|v_n]\), then we use the notation \(\delta^*(q, [u_1\cdots u_k|v_1\cdots v_k])\) to denote \(\delta^*(q, \alpha)\) for simplicity. Note that \([u_1\cdots u_k|v_1\cdots v_k]\) cannot be in \(\Sigma_G\) in general.

We note the following points about \(M_G\) in Definition 6.

1. Intuitively, the state \(q_{i,j} (0 \leq i, j < m)\) in \(M_G\) corresponds to the set consisting of sentential forms \(\tau_1C^pS^qC^rC^t2\) in \(G\) such that \(\tau_1, \tau_2 \in \{C^m\}^*T^+\{C^m\}^*\).
2. An ml-production in \(P(1) \cup P(4)\) produces a unique transition, while an ml-production in \(P(2) \cup P(3)\) produces \(m\) kinds of transitions.

The following lemmas are obvious from Definition 6.

**Lemma 3:** If \(M_G\) has a transition such that either \(j \neq l\) and \(\delta(q_{i,j}, [u|v]) \ni q_{k,l}\) or \(i \neq k\) and \(\delta(q_{i,j}, [u|v]) \ni q_{k,l}\), then \(G\) is not a strict terminal \(\{C^m\}\)-cml grammar.

**Lemma 4:** If a string \(\alpha \in \Sigma_G^+\) is in \(L(M_G)\), then \(\alpha\) is one of the forms: \([u]\) and \([u_1|v_1]\cdots[u_n|v_n][u]\) (\(n \geq 1\)).

In the following, for simplicity, we assume that if \(n = 0\) then \([u_1|v_1]\cdots[u_n|v_n][u] = [u]\).
Theorem 4: For the nondeterministic finite automaton \( M_G \) derived from a terminal \( \{C^n\} \)-cml grammar \( G \), if a string \( [u_1[v_1]\cdots u_n[v_n]]u \) is in \( L(M_G) \), then \( u_1\cdots u_n u_n^R \cdots u_1^R \) is in \( L(G) \).

Proof: Consider a terminal \( \{C^n\} \)-cml grammar \( G = ([S, C], T, P, S) \) and the nondeterministic finite automaton \( M_G = (Q, \Sigma_C, \delta, q_{0,0}, \{q_f\}) \) derived from \( G \).

We will show that if \( \delta(q_{i,j}, [u_1[v_1]\cdots u_n[v_n]]u) \) \( \not\subseteq q_f \) then there is a derivation \( C^iSC_j^r \Rightarrow^* u_1\cdots u_n u_n^R \cdots u_1^R \) by using the induction on \( n \). Note that for the case \( i = j = 0 \), this implies Theorem 4.

Base step, \( n = 0 \): Assume that \( \delta(q_{i,j}, [u]) \not\subseteq q_f \). By the construction of \( \delta \), there is a production \( r: S \rightarrow C^iC^r u \) with \( i = (m-i') \mod m \) and \( j = (m-j') \mod m \). Therefore, there is a derivation \( C^iSC_r^j \Rightarrow^* C^iC^j u \) such that \( \delta(q_{i,j}, [u_1[v_1]\cdots u_n[v_n]]u) \not\subseteq q_f \).

Induction step: For \( n \geq 1 \), assume that \( \delta(q_{i,j}, [u_1[v_1]\cdots u_n[v_n]]u) \not\subseteq q_f \). Then, there is a state \( q_{k,l} \) such that \( \delta(q_{i,j}, [u_1[v_1]]) \not\subseteq q_{k,l} \) and \( \delta(q_{k,l}, [v_2]\cdots [u_n[v_n]]u) \not\subseteq q_f \).

From the induction hypothesis, there is a derivation \( C^kSC_l^r \Rightarrow^* u_{k1}C^kC_l^r u_{l1} \) with \( \delta(q_{k,l}, [v_2]\cdots [u_n[v_n]]u) \not\subseteq q_f \).

There are three cases for \( u_{11} \): (1) \( u_1u_1 \not\in \varepsilon \), (2) \( u_1 = \varepsilon \) and \( u_1 \not\in \varepsilon \), \( v_1 = \varepsilon \). We prove only the first case, since the proof of the other cases is quite similar to the proof of the first case.

Assume that \( u_1u_1 \not\in \varepsilon \). By the construction of \( \delta \), there is a production \( r: S \rightarrow C^iC^j u \) with \( i = (m-i') \mod m \) and \( j = (m-j') \mod m \). Therefore, there is a derivation

\[
C^iSC_j^r \Rightarrow^* C^iC^j u_1C^kC_l^r u_{l1} \Rightarrow^* u_1C^kC_l^r u_{l1}.
\]

\( \square \)

Theorem 5: For a terminal \( \{C^n\} \)-cml grammar \( G = ([S, C], T, P, S) \), if a string \( w \in T^+ \) is in \( L(G) \), then there exists a string \( [u_1[v_1]\cdots u_n[v_n]]u \in \Sigma_C^n \) with \( n \geq 0 \) such that \( w = u_1\cdots u_n u_n^R \cdots u_1^R \) and \( [u_1[v_1]\cdots u_n[v_n]]u \in \Sigma_C^n \).

Proof: We will show that for \( 0 \leq i, j < m \) and \( w \in T^+ \), if there is a derivation \( C^iSC_j^r \Rightarrow^\gamma \) such that \( \delta(q_{i,j}, [u_1[v_1]\cdots u_n[v_n]]u) \not\subseteq q_f \) then there exists a production \( r: S \rightarrow C^iC^j u \) with \( i = (m-i') \mod m \) and \( j = (m-j') \mod m \). By the construction of \( \delta \), there is a transition \( \delta(q_{i,j}, [u]) \not\subseteq q_f \).

Induction step: Assume that there is a derivation \( C^iSC_j^r \Rightarrow^\gamma \) such that \( \delta(q_{i,j}, [u]) \not\subseteq q_f \). Let \( r \) be the first used terminal ml-production in \( \gamma \). There are three cases: \( r \in P(1); r \in P(2); r \in P(3) \). We prove only the case \( r \in P(1) \), since the proof of other cases is similar to the proof of the first case.

Suppose that \( r \in S \rightarrow C^iC^j u \) is a derivation \( C^iSC_j^r \Rightarrow^\gamma \) \( \not\subseteq q_f \) such that \( uu^Rv = w \), only the c-production is applied in \( \gamma_1 \), and ml-productions occur \( n + 1 \) times in \( \gamma_2 \).

Since only the c-production is applied in \( \gamma_1 \), it follows from the definition of \( \delta \) that \( \delta(q_{i,j}, [u]) \not\subseteq q_f \). By the induction hypothesis and \( C^iC^j \Rightarrow^\gamma u \), there exists a string \( \alpha \in \Sigma_C \) such that \( \alpha = [u_1[v_1]\cdots u_n[v_n]]u' \), \( \delta(q_{i,j}, [u]) \not\subseteq q_f \), and \( w' = u_1\cdots u_n u_n^R \cdots u_1^R \). Hence, \( \delta(q_{i,j}, [u]) \not\subseteq q_f \) and \( w = u_1\cdots u_n u_n^R \cdots u_1^R \).

3.3 Inclusion Relation of Terminal \( \{C^n\} \)-cml Language Classes

For two distinct positive integers \( m \) and \( n \), we examine inclusion relations between t-cML\( _{\{C^n\}} \) and t-cML\( _{\{C^m\}} \). First, we show that if \( n \) is a multiple of \( m \) then t-cML\( _{\{C^n\}} \) includes t-cML\( _{\{C^m\}} \).

Theorem 6: For given integers \( m, h \geq 2 \), t-cML\( _{\{C^n\}} \subseteq t\text{-}\text{CML} \).
u, v: (1) u, v \neq \epsilon; (2) u \neq \epsilon, v = \epsilon; (3) u = \epsilon, v \neq \epsilon. We show only the first case, since the proof of the other cases is similar to the proof of this case.

Assume that u, v \neq \epsilon. Then, we have (hx + hi) \mod hm = (hj + hy) \mod hm = 0, which implies (x + i) \mod m = (j + y) \mod m = 0. From the induction hypothesis, there is a derivation C^kSC^j \Rightarrow_G w'. Therefore, there is a derivation C^kSC^j \Rightarrow_G C^kSC^iSC^j \Rightarrow_G u^kC^iC^jv \Rightarrow_G w. \qedsymbol

If n is greater than m then we can show that t-CML_{(C^m)} is not included in t-CML_{(C^m)}.

Theorem 7: If n > m \geq 2 then there exists a terminal [C^m]-cml language that is not a terminal [C^m]-cml language.

Proof: For each k (0 \leq k < n^2), we define f(k) as a pair of integers (i, j) such that k = i \cdot n + j and 0 \leq j < n. Consider a terminal [C^n]-cml grammar G = ((S, C), T, P, S) such that

T = \{a_0, b_0\} \cup \bigcup_{1 \leq i \leq n^2} \{a_i, b_i, d_i\}

and

P = \{S \rightarrow C'^n a_k C^i S C^j a_k C'^m j | 0 \leq k < n^2 \text{ and } f(k) = (i, j)\}

\cup \{S \rightarrow C'^n a_k b_i C'^m j | 0 \leq k < n^2 \text{ and } f(k) = (i, j)\}

\cup \{S \rightarrow d_i C^i C^j d_k | 1 \leq k < n^2 \text{ and } f(k) = (i, j)\}

\cup \{C^n \rightarrow \epsilon\}.

Let L_0 = \{d_i d_k d_0 | 1 \geq 0\} and L_k = \{d_i d_k d_i d_k d_0 | 1 \geq 0\} for k (1 \leq k < n^2). Then, L(G) = \bigcup_{0 \leq k \leq n^2} L_k.

Assume that there is a terminal [C^m]-cml grammar G' such that L(G') = L(G). Let M_{G'} be the nondeterministic finite automaton (Q', \Sigma', \delta', q'_0, (q'_f)) derived from G', where

Q' = \{q'_f | 0 \leq i < m\} \cup \{q'_f\},

\Sigma' = \{|u| | S \rightarrow C'^u C^j | P'\} \cup \{|u| | S \rightarrow C'^u C^j | P'\}.

For each k (0 \leq k < n^2), if a_k occurs in w \in L(G), then w \in L_k. Hence, by Theorem 5, there is a state  \tilde{q}_k \in Q' such that (\delta')^*(\tilde{q}_k, [a_{i_1}^m | a_{j_1}^m]) \Rightarrow  \tilde{q}_k. The set Q' consists of m^2 + 1 states, and there is no transition from the final state q'_f. Hence, it follows from m < n that there are two distinct integers s and t such that 0 \leq s, t < n^2 and  \tilde{q}_s =  \tilde{q}_t. Therefore, (\delta')^*(\tilde{q}_s, [a_{i_1}^m | a_{j_1}^m]) \Rightarrow  \tilde{q}_s holds. By Theorem 4, this implies that there is a string w in L(G) such that both a_s and a_t occur in w. This contradicts L(G) = \bigcup_{0 \leq k \leq n^2} L_k.

Corollary 2: For given integers m, h \geq 2, CML_{(C^m)} \subseteq CML_{(C^m)}.}

3.4 Terminal [C^m]-cml Languages and Strict Terminal [C^m]-cml Languages

We show that the class of terminal [C^m]-cml languages properly includes the class of s-terminal [C^m]-cml languages.

Theorem 8: For a given integer m \geq 2, st-CML_{(C^m)} \subseteq CML_{(C^m)}.

Proof: Since st-CML_{(C^m)} \subseteq CML_{(C^m)} immediately follows from the definitions of the language classes, we show the proper inclusion.

We prove only the case m = 2. We show the outline of the proof of the case m = 2 in Appendix.

Let m = 2. Consider a terminal [C^2]-cml grammar G = ((S, C), T, P, S) such that T = \{a_0, a_1, a_2, d_3, a_1, d_2, d_3, b_0, b_1, b_2, b_3, c_0, e_1, g, h, i\}, and

P = \{S \rightarrow a_0Sd_0, S \rightarrow a_1Scd_1C, S \rightarrow a_2Scd_2, S \rightarrow a_3Scd_3C, S \rightarrow b_0S, S \rightarrow c_1S, S \rightarrow c_2S, S \rightarrow c_3S, S \rightarrow gS, C^2 \rightarrow \epsilon\}.

We will show that L(G) is not in st-CML_{(C^2)}.

Let M_G = ((Q, \Sigma, \delta, q_0, q_f)) be the nondeterministic finite automaton derived from G. Figure 1 shows the transition diagram of M_G.

It is also easy to show that L(G) has the nine properties:

(P1) if w \in L(G), then one and only one of b_0, b_1, b_2 and b_3 occurs in w only one time.

(P2) a_0^2b_0^2a_0 \in L(G) if and only if n = k \geq 0.

(P3) h^2a_0^1a_1^1 \in L(G) if and only if n = k \geq 0.

(P4) g^2a_0^2a_2^2 \in L(G) if and only if n = k \geq 0.

(P5) h^2a_0^1a_2^1a_3^1 \in L(G) if and only if n = k \geq 0.

(P6) if b_0 occurs in w \in L(G) then w has an even number (including zero) of h occurrences, and g does not occur in w.

(P7) if b_1 occurs in w \in L(G) then w has an odd number of g occurrences, and h does not occur in w.

\[ \begin{array}{c}
\text{[e_0]} \ \text{[e_1]} \\
\text{[a_0]} \text{[a_1]} \text{[a_2]} \text{[a_3]} \text{[b_0]} \text{[b_1]} \text{[b_2]} \text{[b_3]} \\
\text{[d_0]} \text{[d_1]} \text{[d_2]} \text{[d_3]} \text{[c_0]} \text{[c_1]} \text{[c_2]} \text{[c_3]} \\
\text{[h]} \text{[e]} \text{[g]} \\
\text{[s]} \text{[t]} \text{[u]} \text{[v]} \text{[w]} \\
\text{[x]} \text{[y]} \text{[z]} \\
\end{array} \]

Fig. 1 The transition diagram of M_G.
Claim 1: For each $i \leq \leq 3$, the following hold.

(a) For each $k \geq 0$, the string $x_i y_i^k z_i u_i t_i \beta_i a_i$ is in $L_i$.

(b) There exists a positive integer $p_i$ such that $y_i = a_i^p$ and $\beta_i = d_i^p$.

(c) The string $z_i u_i t_i$ has only one occurrence of $b_i$.

(d) $x_1$ has only one occurrence of $h$, $x_2$ has only one occurrence of $g$, and $x_3$ has only one occurrence of both $h$ and $g$.

Proof: We prove only the case $i = 1$, since the proof of other cases is similar to the proof of this case.

By Condition (5), there exists $p \geq 0$ such that $x_1 y_1 z_1 u_1 t_1 \beta_1 a_1 = q_0^p b_0 d_0^p$. Hence, it follows from Conditions (6), (7) and Property (P1) that $b_1$ occurs once in $z_1 u_1 t_1$. Similarly, from Conditions (6), (7) and Property (P7), it holds that $h$ occurs once in $x_1$. Therefore, it follows from Condition (6) and Property (P3) that, for each $k \geq 0$, the string $x_1 y_1^k z_1 u_1 t_1 \beta_i a_i$ is in $L_i$, and that there exists a positive integer $p_1$ such that $y_1 = a_1^p$ and $\beta_i = d_1^p$.

Claim 2: For each $i (1 \leq i \leq 3)$, $\hat{q}_i$ is different from $q_0'$.

Proof: First, we note that, since the string $b_0$ is in $L(G) = L(G')$, $P'$ must include the production $S \rightarrow b_0$, which implies $\delta'(q_0, [b_0]) = \{q'_0\}$.

Next, assume that $\hat{q}_i = q_0'$. Then, $(\delta')^*(q_0', [y_i]_G) \ni q_0'$. Therefore, Claim 2 holds.

Claim 3: The states $\hat{q}_0, \hat{q}_1, \hat{q}_2$ and $\hat{q}_3$ are all distinct.

Proof: We show that $\hat{q}_0$ and $\hat{q}_1$ are distinct. If the two states are the same, then it follows from $(\delta')^*([q_0']_G, \beta_0) = \hat{q}_1$. $(\delta')^*([q_1]_G, [y_1]_G) = \hat{q}_1$. $(\delta')^*([q_1], [y_0]_G) = \hat{q}_0$. Therefore, Claim 2 holds.

Claim 4: The state $\hat{q}_0$ is $q_0'$.

Proof: $M_G$ has four states except for the final state $q_f$. Therefore, Claim 4 follows from Claims 2 and 3.

Claim 5: For each $i (4 \leq i \leq 7)$, let $j = i - 4$. Then, $b_j$ is a suffix of $u_i$, and $t_j \beta_i a_i = \epsilon$.

Proof: We prove only the cases $i = 4$ and $5$, because we can similarly prove the cases $i = 6$ and $7$. By a similar argument used in the proof of Claim 1, we can show that there exists a positive integer $p_i$ such that $y_i = e_i^p$. Hence, it follows from Condition (7) that $b_j$ is a suffix of $a_i, t_i, \beta_i$.

Assume that $b_j$ is a suffix of $a_i, t_i$. Then, Conditions (5), (6) and (7) imply that $u_i = e_i^p$ for some $k_i \geq 1$. Since it follows from Claim 3 that $q_i$ is one of $\hat{q}_0, \hat{q}_1, \hat{q}_2$ and $\hat{q}_3$, let $q_i = \hat{q}_k (0 \leq k \leq 3)$. Then, the string $x_i y_i z_i u_i t_i \beta_i a_i$ is in $L(G')$. On the other hand, from the assumption that $b_j$ is a suffix of $a_i, t_i, \beta_i a_i$, it has an occurrence of $b_j$. Furthermore, it follows from Claim 1 that $z_i u_i t_i$ has an occurrence of $b_j$, which contradicts Property (P1). Therefore, $b_j$ is a suffix of $u_i$.

The equation $t_i \beta_i a_i = \epsilon$ follows from Condition (5) and the fact that $b_j$ is a suffix of $u_i$.

Claim 6: For each $i (5 \leq i \leq 7)$, $x_i \neq \epsilon$. In particular, $x_5$ has only one occurrence of $h$, $x_6$ has only one occurrence of $g$, and $x_7$ has only one occurrence of both $h$ and $g$.

Proof: As shown in the proof of Claim 5, if $i = 5$ then $y_i \beta_i = e_i^p$ for some $p_i \geq 1$ holds, and if $i = 6$ or $7$ then $y_i \beta_i = e_i^p$ for some $p_i \geq 1$ holds. On the other hand, if $w \in L_i (5 \leq i \leq 7)$ then neither $e_0$ nor $e_1$ is a prefix of $w$. Therefore, $x_i \neq \epsilon$ and, $h$ (resp. $g, h g$) is a prefix of $x_5$ (resp. $x_6, x_7$). Then, Claim 6 holds.

Claim 7: The states $\hat{q}_5, \hat{q}_6$ and $\hat{q}_7$ are all distinct, and none of them is $q_0'$.

Proof: The proof of the fact that $\hat{q}_5, \hat{q}_6$ and $\hat{q}_7$ are all distinct is similar to the proof of Claim 3.

We will prove that $\hat{q}_5$ is not equal to $q_0'$. Suppose that the two states are the same. Then, $x_5 b_0$ is in $L(G') = L(G)$. On the other hand, it follows from Claim 6 that $x_5 b_0$ has
only one occurrence of \( h \). This contradicts Property (P6). Similarly, we can prove that neither \( \tilde{q}_6 \) nor \( \tilde{q}_7 \) is equal to \( q'_{0,0} \).

We will conclude the proof of Theorem 8. It follows from Claim 7 that one of \( \tilde{q}_5, \tilde{q}_6, \) and \( \tilde{q}_7 \) is equal to \( q'_{0,1} \). Suppose that \( \tilde{q}_5 (5 \leq p \leq 7) \) is equal to \( q'_{0,1} \). Then, since \( \alpha_p = \epsilon \) follows from Claim 5, \( (\delta^*)^p(q_{0,0}^{\epsilon}, [x_p, \epsilon]) \) holds. This contradicts Lemma 3 and the assumption that \( G' \) is an s-terminal \( \{C^3\}-\text{cml} \) grammar. \( \square \)

3.5 Linear Languages and Regular Languages

We show that the class of \( \epsilon \)-free linear languages properly includes the class of terminal \( \{C^m\}\)-cml languages.

**Theorem 9:** For a given integer \( m \geq 2 \), every terminal \( \{C^m\}\)-cml language is linear.

**Proof:** For a terminal \( \{C^m\}\)-cml grammar \( G \), consider a nondeterministic finite automaton \( M_G = (Q, \Sigma, \delta, q_{0,0}, \{q_f\}) \) derived from \( G \). Based on \( M_G \), construct a linear grammar \( G_1 = (N, T, P, N_0, 0 ab) \), where

\[
N = \{N_{i,j} \mid q_{i,j} \in Q\},
\]

\[
P_1 = \{N_{i,j} \rightarrow uN_{k,l}v \mid \delta(q_{i,j}, [u]) \equiv q_{k,l}\} \cup \{N_{i,j} \rightarrow u \mid \delta(q_{i,j}, [u]) \equiv q_f\}.
\]

From Theorems 4 and 5, it is obvious that \( L(G) = L(G_1) \). \( \square \)

We will show that the class of languages generated by terminal \( \{C^m\}\)-cml (resp. s-terminal \( \{C^m\}\)-cml) grammars and the class of \( \epsilon \)-free regular languages are incomparable.

**Theorem 10:** For a given integer \( m \geq 2 \), \( t\)-CML\(_{\{C^m\}} \) (resp. st-CML\(_{\{C^m\}} \)) and REG are incomparable.

**Proof:** Since ML and REG are incomparable ([3]) and ML is included in st-CML\(_{\{C^m\}} \), it suffices to show that there exists a regular language that is not a terminal \( \{C^m\}\)-cml language.

Consider a regular language

\[
L_r = \{a_0|^{k_0}(a_1|^{k_1} \ldots (a_{2m}|^{k_{2m}}) | k_0, k_1, \ldots, k_{2m} \geq 0\}.
\]

Assume that there is a terminal \( \{C^m\}\)-cml grammar \( G = (\{S, C, T, P, S\} \text{ such that } T = \{a_0, a_1, \ldots, a_{2m}\} \text{ and } L_r = L(G) \). Let \( M_G = (\{Q, \Sigma, \delta, q_{0,0}, \{q_f\}\}) \) be the nondeterministic finite automaton derived from \( G \).

For each \( l \) (\( 0 \leq l \leq 2m \)), \( (a_l|^{k_l} \mid k_0 \geq 0) \) is a subset of \( L_r \). It follows from Theorem 5 and \( L_r = L(G) \) that there exist a state \( \tilde{q}_l \in Q \) and integers \( i_l, j_l \geq 0 \) such that \( \delta^*(\tilde{q}_l, [a_l|^{k_l}) \equiv \tilde{q}_l \), and at least one of \( i_l \) and \( j_l \) is greater than 0. Similarly, if \( u, v \in T^* \) such that \( \delta^*(\tilde{q}_l, [u|^{k_l}) \equiv \tilde{q}_l \), then \( a_l|^{k_l}u \) and \( a_l|^{k_l}v \) are substrings of some \( w \in L_r \). Hence, if \( i_l > 0 \) (resp. \( j_l > 0 \)) then \( u \) (resp. \( v \)) is a sequence of \( a_l \). Therefore, if \( \tilde{q}_l = \tilde{q}_l \), then both \( i_l \) and \( j_l \), then both \( i_l = 0 \) and \( j_l = 0 \). This implies that there exist no mutually distinct integers \( l_1, l_2, l_3 \) such that \( 0 \leq l_1, l_2, l_3 \leq 2m \) and \( \tilde{q}_l = \tilde{q}_l = \tilde{q}_l \). That is, \( M_G \) must have at least \( [2m^2 + 1]/2 \) states except for the final state, whereas \( Q \) consists of \( m^2 \) states except for the final state. This is a contradiction. Therefore, \( L_r \) is not a terminal \( \{C^m\}\)-cml language.

Since REG is included in LIN, the following proper inclusion follows from Theorems 9 and 10.

**Theorem 11:** For a given integer \( m \geq 2 \), \( \text{CML}_{\{C^m\}} \subset \text{LIN} \). Note that Theorem 11 can be derived also from Theorems 7 and 9.

4. \( \{C^*\}\)-cml Languages

We consider the union of \( \text{CML}_{\{C^*\}} \) over all \( m \geq 1 \) in this section.

**Definition 7:** A language \( L \) is a \( \{C^*\}\)-cml language (resp. terminal \( \{C^*\}\)-cml language) if there is some integer \( m \geq 1 \) such that \( L \) is a \( \{C^m\}\)-cml language (resp. terminal \( \{C^m\}\)-cml language). Let \( \text{CML}_{\{C^*\}} \) (resp. \( \text{t-CML}_{\{C^*\}} \)) be the class of \( \{C^*\}\)-cml languages (resp. terminal \( \{C^*\}\)-cml languages).

From Definition 7 and Theorems 3 and 9, the following are obvious.

\[
\cup_{m \geq 1} \text{t-CML}_{\{C^m\}} = \text{t-CML}_{\{C^*\}} = \text{CML}_{\{C^*\}} \subset \text{LIN}.
\]

**Lemma 5:** An \( \epsilon \)-free linear language is a terminal \( \{C^*\}\)-cml language.

**Proof:** Consider an \( \epsilon \)-free linear language \( L = L(G) \), where \( G = (N, T, P, N_0) \) and \( N = \{N_0, \ldots, N_{m-1}\} \). Without loss of generality, we may assume that any production in \( P \) is of one of the forms \( N_p \rightarrow \tau q_r, N_p \rightarrow q_r \tau, N_p \rightarrow \tau \), where \( \tau \in T^+ \) and \( N_p, q_r \in N \).

We construct a terminal \( \{C^*\}\)-cml grammar \( G' = ((S, C), T, P', S) \) as follows: \( P' = P_r \cup P_f \cup P_c \), where

\[
P_r = \{S \rightarrow C^n \tau C^n S C^n \mid N_p \rightarrow \tau q_r, N_p \rightarrow q_r \tau, N_p \rightarrow \tau, \quad y = (n - q - p) \text{ mod } n\}
\]

\[
P_f = \{S \rightarrow C^n S C^n \tau C^n \tau \mid N_p \rightarrow q_r \tau, \quad x = (n - q - p) \text{ mod } n\}
\]

\[
P_c = \{C^n \rightarrow \epsilon\}
\]

We will show that for any \( z \in T^+ \) and any \( N_p \in N \), there is a derivation \( \phi : N_p \rightarrow_G z \) if and only if there is a derivation \( \gamma : C^n S C^n \rightarrow_G z \). Note that for the case \( p = 0 \), this implies that a string \( z \) is in \( L(G) \) if and only if \( z \) is in \( L(G') \).

**[Only-if part]:** We use induction on the length \( k \) of \( \phi \).

Base step, \( k = 1 \): Assume that there is a derivation \( \delta : N_p \rightarrow_G z \), where \( N_p \in N \) and \( z \in T^+ \). For a production \( N_p \rightarrow z \) in \( P, \) from the construction of \( P_r, \) there is a production \( r : S \rightarrow C^m \tau C^n \tau C^m \tau \) in \( P' \). Therefore, there is a derivation \( C^n S C^n \rightarrow_G \gamma : C^m \tau C^n \tau C^m \tau C^n \rightarrow_G z \).

Induction step: Consider a derivation \( \phi : N_p \rightarrow_G \alpha \rightarrow_G z \), where the length of \( \phi \) is \( k + 1 \), \( N_p \in N \), \( z \in T^+ \), and
There are two cases for \( r \): (1) \( r \) is \( N_p \to \tau N_q \), and (2) \( r \) is \( N_q \to \tau p \). We prove only the first case, since the proof of the second case is similar to the proof of the first case.

Then, the derivation \( \phi \) becomes \( \phi : N_p \Rightarrow_G' \tau N_q \Rightarrow_G' \tau' \). For the production \( r \), from the construction of \( P'_r \), a production \( r' : S \to C^\tau \), where \( y = (n+q-p) \) mod \( n \). For a derivation \( N_q \Rightarrow_G' \tau' \), from the induction hypothesis, there is a derivation \( C^\tau \Rightarrow_{G'} \tau' \). Therefore, there is a derivation \( C^\tau \Rightarrow_{G'} \tau' \), where \( \tau' \) is a sequence of the c-production.

**If part:** We use induction on the number \( k \) of ml-productions that occur in \( y \).

Base step, \( k = 1 \): Assume that there is a derivation \( \gamma : C^\tau \Rightarrow_{G'} \tau, \) where \( 0 \leq p < n, \tau \in T^+ \), and only one ml-production occurs in \( \gamma \). Then, the ml-production is \( r : S \to C^\tau \). Since \( r \) is in \( P'_r \), it follows from the construction of \( P \) that \( N_q \Rightarrow_{G'} \tau \). Therefore, there is a derivation \( N_q \Rightarrow_{G'} \tau \).

Induction step: Consider a derivation \( \gamma : C^\tau \Rightarrow_{G'} \tau, \) where \( r \) is an ml-production, ml-productions occur \( k \) times in \( \gamma \), and \( \tau \in T^+ \). There are two cases for \( r \): (1) \( r \in P'_r \); (2) \( r \in P'_r \). We prove only the first case, since the proof of the second case is similar to the proof of the first case.

Let \( r \in P'_r \). Then, it follows from the definition of \( P'_r \) that \( r \) is \( S \to C^\tau \), where \( y = (n+q-p) \) mod \( n \), and \( N_q \to \tau p \) in \( P \). Hence, the derivation \( \gamma : C^\tau \Rightarrow_{G'} \tau, \) where \( \gamma \) is a sequence of \( k \) times in \( \gamma \), and \( \tau \in T^+ \). From the induction hypothesis, there is a derivation \( N_q \Rightarrow_{G'} \tau \). Therefore, there is a derivation \( N_q \Rightarrow_{G'} \tau \).

From Lemma 5, we have the following theorem.

**Theorem 12:** \( \text{CML}_{\{C\}} = \text{t-CML}_{\{C\}} = \text{LIN} \).

### 5. Concluding Remarks

We examined the generative power of \( \{C^m\} \)-cml grammars. Figure 2 illustrates major results proved in this paper. We also showed the following:

1. if \( n \) is a multiple of \( m \) and \( n,m \geq 2 \) then \( \text{t-CML}_{\{C^m\}} \) properly includes \( \text{t-CML}_{\{C^m\}} \).
2. if \( n,m \geq 2 \) then \( \text{t-CML}_{\{C^m\}} \) is not included in \( \text{t-CML}_{\{C^m\}} \).

The question of whether \( \text{t-CML}_{\{C^m\}} \) and \( \text{t-CML}_{\{C^m\}} \) are incomparable for \( n,m \geq 2 \) is open except for the case where \( n \) is a multiple of \( m \).

In this paper, we only considered the generative power of cancel minimal linear grammars with a unique nonterminal symbol except S. As noted in Sect. 2, Geffert [1] shows other types of cml grammars, for example,

### Acknowledgments

The authors would like to express deeply their gratitude to T. Yokomori for useful discussions and valuable suggestions. The authors are also indebted to anonymous reviewers for their valuable comments that improved the contents of this paper. This work was supported in part by Grants-in-Aid for scientific research from the Ministry of Education, Culture, Sports, Science and Technology of Japan (No. 23740081).

### Appendix: Proof Outline of Theorem 8: General Case

We show that for \( m \geq 2 \), there exists a terminal \( \{C^m\} \)-cml grammar \( G \) such that no strict terminal \( \{C^m\} \)-cml grammar \( G' \) generates \( L(G) \).

The outline of the proof is similar to the proof of
the case $m = 2$. Consider a terminal $\{C^n\}$-cml grammar $G = ([S, C], T, P, S)$ such that

$$T = \{ a_{ij} \mid 0 \leq i, j < m \} \cup \{ b_{ij} \mid 0 \leq i, j < m \} \cup \{ d_{ij} \mid 0 \leq i, j < m \} \cup \{ e_i \mid 0 \leq i < m \} \cup \{ g_1, g_2, \ldots, g_{m-1}, h \},$$

and

$$P = \{ S \rightarrow C^{m-i}a_iC^kS^lC_{i,j}C^{m-k} \mid 0 \leq i, k < m \} \cup \{ S \rightarrow C^{m-i}b_iC^kS^l \mid 0 \leq i < m \} \cup \{ S \rightarrow C^{m-i+1}C_0C^iS^l \mid 1 \leq i < m \} \cup \{ S \rightarrow hSC, C^m \rightarrow \varepsilon \}.$$ 

We can construct from $G$ the nondeterministic finite automaton $M_G = (Q, \Sigma, \delta, q_0, \{ q_f \})$. The transition mapping $\delta$ is defined as, for $0 \leq i, j < m$ and $1 \leq k < m$,

$$\delta(q_{i,j}, [a_{i,j} \mid d_{i,j}]) = \{ q_{i,j} \}, \quad \delta(q_{i,j}, [b_{i,j}]) = \{ q_f \}, \quad \delta(q_{i,j}, [e_i]) = \{ q_{i,j} \}, \quad \delta(q_{k-1,j}, [g_k \mid \varepsilon]) = \{ q_{k,j} \}, \quad \delta(q_0, [h \mid \varepsilon]) = \{ q_{0,j+1} \},$$

where we assume $q_{0,m}$ is equal to $q_{0,0}$.

In the following, for $i = 0$, we assume that $h^0 = g_1 \cdots g_i = \varepsilon$. Then, it is easy to show that, for $0 \leq i, j < m$, the following sets are subsets of $L(G)$:

$$L_{i,j} = \{ h^i g_1 \cdots g_i d_{i,j} h_{i,j} d_{i,j}^n \mid n \geq 0 \}$$

$$L_{m+i,m+j} = \{ h^i g_1 \cdots g_i e_i h_{i,j} \mid n \geq 0 \}$$

The language $L(G)$ has the properties:

1. if $w \in L(G)$, then $w$ has only one occurrence of $b_{i,j}$ ($0 \leq i, j < m$), and none of them occur in $w$ at the same time.
2. for $0 \leq i, j < m$, $h^i g_1 \cdots g_i d_{i,j} h_{i,j} d_{i,j}^n \in L(G)$ if and only if $n = 0$.
3. if $b_{i,j}$ occurs in $w \in L(G)$ then the number of $h$ occurrences in $w$ is congruent to $j$ modulo $m$, and $g_k$ ($1 \leq k \leq i$) occurs in $w$ only once.

Assume that there exists an s-terminal $\{C^n\}$-cml grammar $G' = ([S, C], T', P', S)$ such that $L(G) = L(G')$. Let $M_G = (Q', \Sigma', \delta', q_{0,0}, \{ q'_f \})$ be the nondeterministic finite automaton derived from $G'$.

We can show several claims similar to the claims showed in the proof of the case $m = 2$. Therefore, we can derive a contradiction. □

Kaoru Fujioka was born in Tokyo, Japan. Her maiden name is Kaoru Onodera. She received B.S., M.S. and Ph.D. degrees from Waseda University, Tokyo, Japan, in 2000, 2002, and 2007, respectively. From 2006 to 2009, she was an instructor in Department of Science and Engineering, Tokyo Denki University. She is currently an Assistant Professor in the Office for Strategic Research Planning, Kyushu University, Fukuoka, Japan. Her current research interests include formal language theory, DNA computing, and computational learning theory.

Hirofumi Katsuno received B.S. and M.S. degrees in mathematics, and Ph.D. degree in mathematical science from the University of Tokyo. From 1976 to 2000, he was with NTT (Nippon Telegraph and Telephone Corporation). He is currently a professor in Department of Science and Engineering, Tokyo Denki University. His current research interests are artificial intelligence, database and computing theory.
