Electron Microscopic Detection of Single Membrane Proteins by a Specific Chemical Labeling

Shigekazu Tabata, Marijo Jevtic, Nobutaka Kurashige, ..., Itaru Hamachi, Ryuichi Shigemoto, Akio Ojida

HIGHLIGHTS
Developed peptide tag/probe pair enables specific chemical labeling of proteins
Chemical labeling visualizes GPCRs on cell surface with 1.4-nm gold particles
Chemical labeling has higher spatial resolution than immunogold labeling in EM
Chemical labeling shows a few times higher efficiency than immunogold labeling

SUMMARY
Electron microscopy (EM) is a technology that enables visualization of single proteins at a nanometer resolution. However, current protein analysis by EM mainly relies on immunolabeling with gold-particle-conjugated antibodies, which is compromised by large size of antibody, precluding precise detection of protein location in biological samples. Here, we develop a specific chemical labeling method for EM detection of proteins at single-molecular level. Rational design of α-helical peptide tag and probe structure provided a complementary reaction pair that enabled specific cysteine conjugation of the tag. The developed chemical labeling with gold-nanoparticle-conjugated probe showed significantly higher labeling efficiency and detectability of high-density clusters of tag-fused G protein-coupled receptors in freeze-fracture replicas compared with immunogold labeling. Furthermore, in ultrathin sections, the spatial resolution of the chemical labeling was significantly higher than that of antibody-mediated labeling. These results demonstrate substantial advantages of the chemical labeling approach for single protein visualization by EM.

INTRODUCTION
Electron microscopy (EM) is a powerful technique for detecting localization and distribution of a protein of interest (POI) in biological specimens at a nanometer resolution. The most common approach in EM detection of POI is immunogold labeling, in which POI is specifically labeled with a high-electron-density gold particle by using specific antibodies (Faulk and Taylor, 1971). However, immunogold labeling usually suffers from inherent problems, which are mainly associated with the large molecular size of antibody (ca. 150 kDa). First, the use of bulky primary and secondary antibodies locates gold particles 20–30 nm away from POI (Fijita et al., 2007), precluding precise detection of protein location in biological samples. Second, the bulkiness of antibody limits simultaneous labeling of different components of a protein complex. Since numerous proteins function by forming permanent or transient protein complexes in living cells (Srihari et al., 2015; Havugimana et al., 2012), this limitation dramatically diminishes the utility of EM in protein analysis. Third, the large molecular size of antibody hinders its penetration into biological specimens, making it challenging to quantitatively compare POI localization along tissue depth (Masugi-Tokita and Shigemoto, 2007). Fourth, the development of an antibody that is highly selective toward POI is often technically demanding. Chemical protein labeling methods using small molecular probe could potentially overcome these problems. However, despite their extensive use in fluorescence imaging, application to single-protein detection by EM is yet to be reported.

The method for covalent labeling of proteins with a synthetic chemical probe enables functional analyses of POI under biological conditions. Various protein labeling methods have been devised over the past 20 years and mainly used for fluorescence imaging of POI under live cell conditions (Xue et al., 2015; Dean and Palmer, 2014; Krall et al., 2016). Among them, specific cysteine conjugation using reactive peptide tag-probe pair has attracted considerable attention (Schneider and Hackenberger, 2017; Lotze et al., 2016). The pioneering work of Tsien and co-workers led to the development of a method employing a genetically encoded short peptide tag (CysCysXXCysCys) and a biarsenical probe (Griffin et al., 1998). Since then, several peptide tag-based approaches, including oligohistidine tag (His6–10) (Martos-Maldonado et al., 2018; Uchinomiya et al., 2013), π-clamp (Phe-Cys-Pro-Phe) (Zhang et al., 2016), and CX10R7 tag (VTNQECCSIPM) (Ramil et al., 2016), have been devised for specific protein labeling. As a different
approach, various enzyme-mediated labeling methods for tag-fused proteins (SNAP-tag, Halo-tag, and lipoic acid ligase) have also been developed (Walper et al., 2017). Compared with these enzymatic approaches, the chemical labeling methods using the tag-probe pair benefit from high tolerability of labeling conditions (including pH, solvent composition, chemical fixation), flexibility in probe design independent from substrate specificity of enzymes, and small molecular size of the tag and the probe, which allows location of the labeled probe at close position to POI. All these properties would increase utility of the chemical labeling method in high-resolution protein analysis by EM, which often needs to handle chemically fixed cell and tissue.

We have previously reported the selective covalent labeling of protein using a complementary recognition pair of a peptide tag and a reactive zinc complex (Figure 1A) (Nonaka et al., 2010). In this tag-probe pair, the interaction between the aspartate-rich peptide tag (D4-tag; CAAAAAADDDDGDDDD) and the tetranuclear zinc complex (Zn(II)-DpaTyr) induces their cysteine conjugation. However, the overly reactive α-chloroacetamide group of the zinc complex often induced non-specific labeling, hampering its wide use in fluorescence analysis of proteins. This problem prompted us to develop a new tag-probe pair, which has an improved labeling selectivity while retaining a high reactivity. In this manuscript, we report the development of a new peptide tag-probe pair for specific protein labeling and its application to EM detection of membrane proteins at single-molecular level. The high labeling selectivity of this chemical labeling overcame the problem of the non-specific labeling, enabling EM detection of the labeled G protein-coupled receptor (GPCR) in cell membrane freeze-fracture replicas and ultrathin sections. The efficiency and resolution obtained by the chemical labeling was significantly higher than those obtained by the immunogold labeling. The chemical labeling method also revealed high-density clusters of molecules closer than a few nanometers to each other, demonstrating its utility in single protein detection by EM.

**RESULTS AND DISCUSSIONS**

**Design of α-Helical Peptide Tag**

The selective chemical labeling of proteins would be achieved by utilizing a pair of highly reactive peptide tag and probe with a tuned weak reactivity. On the basis of this strategy, we initially developed a highly
We then modified the sequence of peptide-\(d\) to lower the \(pK_a\) value of the cysteine thiol. It is known that the family of glutaredoxin proteins share a common -Cys-Pro-Xaa-Cys- motif in the active site and that the cysteine thiol positioned at the N terminus has an extremely low \(pK_a\) value (ca. 3.8) (Jao et al., 2006; Floppe and Nilsson, 2007). On this basis, we designed peptide-\(e\) (Table 1) with an N-terminal -Cys-Pro-Tyr-Ala- sequence mimicking yeast glutaredoxin. The \(pK_a\) of the cysteine thiol of peptide-\(e\) in the absence of \(2\-4Zn(II)\) was determined to be 8.48, which was lower by approximately 0.4 pH unit than that of peptide-\(d\) \((pK_a = 8.89)\). Another strategy of lowering the \(pK_a\) value of cysteine thiol was the introduction of a positively charged amino acid, which can electrostatically stabilize an adjacent cysteine residue (Lutolf et al., 2001). We thus designed peptide-\(g\) and peptide-\(h\), which possess two Lys or Arg residues at the N termini, respectively. The \(pK_a\) values of these peptides \((pK_a = 8.04\) and 8.02\,) respectively were apparently lower than that of peptide-\(e\) \((pK_a = 8.48)\), indicative of electrostatic stabilization of the thiolate anion by the
positively charged amino acid residues. Most interestingly, the \( pK_a \) values of all peptides largely decreased by approximately 1 pH unit in the presence of \( 2-4\text{Zn(II)} \). The lowest \( pK_a \) value (\( pK_a = 7.13 \)) was observed in the binding complex of peptide-\( g \) with \( 2-4\text{Zn(II)} \). Conversely, the previously developed peptide-i (D4-tag) (Nonaka et al., 2010) showed the highest \( pK_a \) value (\( pK_a = 8.22 \)) among the peptides.

The first-order reaction rate constant (\( k, s^{-1} \)) of the peptides with mCBI under neutral aqueous solution (50 mM HEPES, 100 mM NaCl, pH 7.2, 37\(^\circ\)C) is summarized in Table 1. Notably, the reaction rate order correlated well with that of the \( pK_a \) value of the cysteine thiol. That is, a peptide with a low \( pK_a \) exhibited high reactivity, suggesting that the thiolate anion served as the main reactive species in the nucleophilic reaction with mCBI. Furthermore, \( 2-4\text{Zn(II)} \) accelerated the reaction of all \( \alpha \)-helical peptides (peptides-\( d \)–h) with mCBI, consistent with their low \( pK_a \) values in the binding complex. The most reactive peptide was peptide-\( g \): its reaction rate in the presence of \( 2-4\text{Zn(II)} \) (\( k = 7.60 \times 10^{-2} \text{ s}^{-1} \)) was over ten times higher than that of the initially designed peptide-\( d \) in the absence of \( 2-4\text{Zn(II)} \) (\( k = 0.66 \times 10^{-2} \text{ s}^{-1} \)). These observations demonstrated the validity of our strategy to gain a highly reactive peptide tag by lowering the \( pK_a \) value of the cysteine.

**Tuning of Probe Reactivity for Enhanced Labeling Selectivity**

To reduce the non-specific labeling activity of the \( \text{Zn(II)} \) complex, we next tuned its reactivity. Michael acceptor is an important class of reactive group for cysteine thiol and has been widely used for protein modification with synthetic probes and covalent drugs (Singh et al., 2010). Considering the broad tunability of its reactivity (Flanagan et al., 2014), we prepared the monomer-type zinc complexes \( 3-2\text{Zn(II)} \) to \( 5-2\text{Zn(II)} \) bearing a different Michael acceptor group (Figure S3) and evaluated their reactivity with peptide-\( g \) by using mCBI. The kinetic analysis revealed that the reactivity of \( 5-2\text{Zn(II)} \) (\( t_{1/2} = 3.98 \text{ h} \)) bearing a \( \gamma \)-dimethylamino crotonate (DMAC) (Wissner et al., 2003) as Michael acceptor group was substantially lower than that of \( \alpha \)-chloroacetamide \( 6-2\text{Zn(II)} \) (\( t_{1/2} = 0.20 \text{ h} \)). These data suggested the potential utility of DMAC as a reactive group of the labeling probe with a moderate reactivity. The other Michael acceptor-type probes \( 3-2\text{Zn(II)} \) and \( 4-2\text{Zn(II)} \), which bears a cinnamide and crotonamide, respectively, showed the low reactivity with peptide-\( g \) (\( t_{1/2} > 24 \text{ h} \)).

We next evaluated the reactivity of dimer-type zinc complexes \( 7-4\text{Zn(II)} \) to \( 9-4\text{Zn(II)} \) bearing a DMAC group (Table 2). Their reactivity was evaluated with peptide-\( g \) to peptide-i, which possessed the different number of alanine residue(s) for optimization of spatial orientation between the cysteine residue and the bound \( \text{Zn(II)} \) complex. Interestingly, the reactivity was greatly affected by the structure of the \( \text{Zn(II)} \) complex: the reaction rate of \( 9-4\text{Zn(II)} \), possessing a rigid L-proline linker, with peptide-\( g \) (\( t_{1/2} = 0.74 \text{ h} \)) was higher than that of \( 7-4\text{Zn(II)} \) (\( t_{1/2} = 3.3 \text{ h} \)). In contrast, \( 8-4\text{Zn(II)} \) possessing an ethylene glycol linker exhibited a

| Peptide | \( \text{Zn(II)} \) (-) | \( \text{Zn(II)} \) (+) |

much lower reactivity ($t_{1/2} = 13.9$ h). The reactivity was also influenced by the number of inserted alanine(s) in the peptide tag: peptide-k, which possessed two additional alanine residues, showed a higher reactivity ($t_{1/2} = 0.22$ h) for 9-4Zn(II) compared with peptide-g ($t_{1/2} = 0.74$ h). Consequently, 9-4Zn(II) and peptide-k were identified as the optimized tag-probe pair with the highest reactivity. We confirmed that the $pK_a$ values of peptides with inserted alanine(s) (peptide-j and -k) in a binding complex with 2-4Zn(II) were 7.08 and 7.14, respectively, which were comparable with that of peptide-g ($pK_a = 7.13$) (Figure S4). Overall, the reactivity of the optimized tag-probe pair (i.e., 9-4Zn(II) and peptide-k, $t_{1/2} = 0.22$ h) was approximately 30-fold higher than that of the previously developed D4-tag peptide-i with the structurally unoptimized 7-4Zn(II) ($t_{1/2} = 6.78$ h, Table 2).

Table 2. Summary of the Reaction Half-Time ($t_{1/2}$, h) of the Zinc Complexes with the Peptides

| Peptide         | $t_{1/2}$ (h) | 7-4Zn(II) | 8-4Zn(II) | 9-4Zn(II) |

*Not determined.

Fluorescence Labeling of HelixD2-Tag-Fused Protein

The optimized tag-probe pair was used for fluorescence labeling of tag-fused proteins. We first employed maltose-binding protein (MBP) tagged with the 21-amino acid peptide-k, named helixD2-tag (KKCPYSADAADAADA). The labeling reaction of helixD2-MBP was conducted with the fluorescent zinc complex 10-4Zn(II) bearing an Oregon green 488 under aqueous buffer conditions (50 mM HEPES, 100 mM NaCl, pH 7.2) (Figure 3A). In-gel fluorescent analysis revealed that the labeling reaction proceeded in a time-dependent manner (Figures 3B and 3C). The half reaction time ($t_{1/2}$) was determined to be 0.28 h by pseudo-first-order kinetic analysis, which was comparable with that of the reaction between peptide-k and 9-4Zn(II) ($t_{1/2} = 0.22$ h, Table 2). The second-order reaction rate constant of the labeling reaction of helixD2-MBP with 9-4Zn(II) was also determined to be $9.4 \times 10^2$ M$^{-1}$ s$^{-1}$ by the detailed kinetic analysis (Figure S5). A control labeling reaction was conducted using MBP tagged with the cysteine-containing histidine-rich peptide (CH6 tag: CHHHHHH). As shown in Figure 3B, no labeling adduct was detectable with CH6-MBP, consistent with the weak binding affinity of the zinc complex and hexahistidine peptide ($K_a < 10^3$ M$^{-1}$) (Uchinomiya et al., 2014).

We next applied the tag-probe pair to the covalent labeling of GPCR protein on the cell surface. In the experiment, bradykinin receptor type 2 (B2R) was tagged with a helixD2-tag (located at the extracellular
N-terminal region of B2R) and transiently expressed in HEK293 cells. When the cells were pre-treated with tris(2-carboxyethyl)phosphine (TCEP) to activate the cysteine residue of the tag, and then incubated with 4 mM Mo f10-4Zn(II) for 30 min at 37°C, the bright fluorescence signal was observed on the cell surface (Figure 3D). The obtained fluorescence image overlapped well with that of the fluorescent B2R antagonist peptide, indicative of selective covalent labeling of the tag-fused B2R by 10-4Zn(II). The fluorescence of 10-4Zn(II) was not observed on the cell surface when the labeling reaction was conducted in the presence of 1 mM inorganic pyrophosphate (PPi), a strong binder to the zinc complex (Figure S6). Similarly, the labeling of HEK293 cells expressing B2R tagged with CH6 did not show any fluorescence on the cell surface (Figure 3E). These data suggest that the selective binding between the helixD2-tag and 10-4Zn(II) is essential for the efficient covalent labeling of B2R.

To evaluate the non-specific labeling activity of the probes on the cell surface, HEK293 cells that did not express B2R were treated with 10-4Zn(II) or α-chloroacetamide probe 11-4Zn(II) (4 μM, 37°C), and the fluorescence of the cell surface was quantified by confocal microscopy with a high laser power after formaldehyde fixation (Figures 3F and 3G). The result revealed that the fluorescence of 10-4Zn(II) associated with non-specific reaction was apparently weaker than that of the highly reactive 11-4Zn(II). The labeling of HEK293 cells expressing B2R tagged with CH6 did not show any fluorescence on the cell surface (Figure 3E). These data suggest that the selective binding between the helixD2-tag and 10-4Zn(II) is essential for the efficient covalent labeling of B2R.
revealed that the band intensities of proteins non-specifically labeled by 10-4Zn(II) were significantly lower than those labelled by 11-4Zn(II).

**EM Detection of Tag-Fused Protein Using Biotin and Nanogold-Conjugated Probes in Freeze-Fracture Replica**

We applied chemical labeling to EM detection in combination with sodium dodecyl sulfate (SDS)-digested freeze-fracture replica labeling (SDS-FRL) technique (Fujimoto, 1995). This technique is widely used to detect the two-dimensional distribution of membrane proteins on protoplasmic (P-) and exoplasmic (E-) leaflet of lipid bilayer in freeze-fracture replicas (Meier and Beckmann, 2018). In the current study, we first used the biotin probe 12-4Zn(II) to detect helixD2-B2R-EGFP, which harbored an extracellular N-terminal helixD2-tag and an intracellular C-terminal enhanced green fluorescent protein (EGFP) (Figure 4A). The labeling specificity of 12-4Zn(II) toward helixD2-B2R-EGFP was confirmed by fluorescence imaging using Alexa Fluoro 633-conjugated streptavidin (SA) (Figure S8). For EM detection, helixD2-B2R-EGFP, expressed on the surface of live HEK293 cells, was labeled with 12-4Zn(II) followed by secondary labeling with SA-conjugated 1.4-nm gold particle. After fixation with paraformaldehyde, a complementary

Distribution histograms of nearest neighbor distance (NND) of gold particles observed on replicas labeled with 13-4Zn(II) (upper, n = 1748 particles) and anti-FLAG antibody (bottom, n = 998 particles). Fitted lines show Gaussian distribution fitting for the peaks. 

Comparison of the number of particles per B2R cluster labeled with 13-4Zn(II) and anti-FLAG antibody. “Max 12 nm” and “Max 42 nm” mean the maximum NND of gold particles used for the definition of clusters labeled with 13-4Zn(II) and anti-FLAG antibody (13-4Zn(II)) Max 12 nm, n = 10 cells, 13-4Zn(II) Max 42 nm, n = 10 cells; anti-FLAG Max 42 nm, n = 7 cells, mean ± SE, **p < 0.01, Mann-Whitney U test. 

Comparison of the B2R cluster area evaluated by chemical labeling with 13-4Zn(II) and immunolabeling with anti-FLAG antibody (13-4Zn(II)) Max 12 nm, n = 10 cells, 13-4Zn(II) Max 42 nm, n = 10 cells; anti-FLAG 42 nm, n = 7 cells, mean ± SE, n.s. p > 0.05, Mann-Whitney U test). 

A pair of P- and E-face freeze-fracture replica was prepared using the double replica method (Figure 4A). One replica of the pair underwent silver enhancement to increase the visibility of 1.4-nm gold particles labeled by the chemical labeling on the E-face. In another replica of the pair, EGFP was immunolabeled with 5-nm gold particles to detect helixD2-B2R-EGFP on the P-face. EM analysis revealed selective labeling of EGFP on the corresponding P-face (Figures 4B and 4D) and vice versa, selective labeling of EGFP on the extracellular domain of B2R (Figures 4C and 4E). These observations are consistent with the extracellular location of the helixD2-tag and the intracellular location of EGFP. 

Although the density of gold particles looked higher for EGFP than helixD2-tag, it is necessary to visualize each of them on the E-face to compare the labeling efficiency, because the allocation of helixD2-B2R-EGFP to the P-face and E-face can be different. In addition, binding of the biotin probe 12-4Zn(II) and SA-conjugated particle can be disrupted by SDS treatment at 60°C reducing the labeling efficiency. Thus, we next used 13-4Zn(II), which possesses a directly conjugated 1.4-nm nanogold particle to label helixD2-B2R-EGFP, and anti-FLAG antibody to label FLAG tag, which was inserted just next to the helixD2 tag in the extracellular domain of B2R (Figure 5A). Probe 13-4Zn(II) was obtained by conjugation reaction of the amine probe 14-4Zn(II) with mono-sulfo-N-hydroxy-succinimide nanogold particles in HEPES buffer (pH 8.0), which was followed by dialysis to remove excess of 14-4Zn(II). The labeling reaction of 13-4Zn(II) was conducted for an extended time (2 h, 37°C) to fully label helixD2-B2R-EGFP expressed on HEK293 cells. To facilitate searching for E-face labeled with 1.4-nm gold particles by 200kV scanning transmission electron microscope (dark field mode), GluA2 subunit of α-amino-3-hydroxy-5-methyl-4-isoxazole-propionic acid-type glutamate receptor was co-expressed with helixD2-B2R-EGFP in HEK cells and labeled with 10-nm gold particles by an antibody for an extracellular epitope of GluA2 combined with anti-rabbit 10-nm gold particle-conjugated secondary antibody (Figure S9). On GluA2-labeled E-face, we found numerous 1.4-nm gold particles, often making high-density clusters of particles (Figures 5B and 5C). The specificity of the labeling was confirmed using HEK cells transfected with GluA2 but not with helixD2-B2R-EGFP (Figure 5D). The density of background labeling (5.9 particles/μm²) was 1.7% of the specific labeling (353 particles/μm²) (Figure 5H). In the immunogold labeling, the specific labeling by anti-FLAG tag antibody was observed on the E-face with 5-nm particles (125 particles/μm², n = 7 cells, Figure 5H), also showing clusters of particles (arrowheads in Figure 5G). The average density of B2R labeled with 13-4Zn(II) was 2.8 times higher than that with anti-FLAG antibody (Figure 5H, p < 0.05).
demonstrated the high utility of the chemical labeling method for SDS-FRL using fixed biological samples.

et al., 2017; Matsuo and Hamachi, 2017) are difficult to apply to denatured proteins by fixation, these results
Since the majority of the existing enzyme-mediated and ligand-directed protein labeling methods (Walper
and 5H). This was indicative of the compatibility of the developed chemical labeling with aldehyde fixation.

In typical SDS-FRL experiment, biological samples, such as sliced tissue, are initially fixed with aldehyde to
maintain protein location by physical stabilization (Masugi-Tokita and Shigemoto, 2007). Therefore, we
next applied the chemical labeling to the fixed cell samples. HEK293 cells expressing helixD2-B2R-EGFP
were first fixed with 2% paraformaldehyde and then labeled with

In summary, we have achieved EM detection of GPCR by chemical labeling using a reactive peptide tag-
probe pair. Rational design of the highly reactive α-helical peptide tag and the fine-tuning of probe reac-
tivity enabled the specific cysteine conjugation of the tag-fused B2R protein on cell surface. EM detection
using the tag-probe pair was successfully applied to determine the localization of B2R receptor on cell sur-
face with a high labeling specificity. Furthermore, the probe directly conjugated with a 1.4-nm gold particle

EM Detection of Tag-Fused Protein Using Nanogold-Conjugated Probes in Ultrathin Section
To further confirm higher resolution of the chemical labeling using 13-4Zn(II), we performed EM analysis of ultrathin sections of resin-embedded HEK293 cells. We compared the distances from the silver-intensi-
sified 1.4-nm gold particles to cell membrane between the samples labeled by 13-4Zn(II) and those
labeled by anti-FLAG antibody combined with 1.4-nm gold-particle-conjugated secondary antibody (Fig-
ures 6A and 6C). The background density of particles examined in non-transfected cells was 0.8% and
0.6% of the specific labeling by 13-4Zn(II) and anti-FLAG antibody, respectively. The silver-intensified
gold particles appeared to be mostly attached to the cell membrane in the chemical labeling (Figure 6B),
whereas those in the FLAG immunolabeling showed apparent gaps between the particles and the cell
membrane (Figure 6D). Considering that silver intensification may occur in a non-isotropic/concentric
manner around 1.4-nm gold particles, we used minimum time (3–6 min) for silver intensification and
examined the correlation of the size of silver-intensified particles and the distance between the center
of silver-intensified particles and the midpoint of lipid bilayer (Figure 6E). We found a significant positive
correlation for both chemical labeling ($r_s = 0.24, p < 0.01, n = 147$ particles) and immunolabeling ($r_s =
0.26, p < 0.01, n = 228$ particles). By extrapolating linear fits, estimated distances of non-intensified
1.4-nm particles were calculated to be 5.4 nm and 9.9 nm for chemical labeling and immunolabeling,
respectively. Since the half thickness of lipid bilayer was estimated to be 4 nm by EM analysis (Robertson,
1958), the distance of 1.4-nm gold particles from the cell surface was deduced to be 1.4 and 5.9 nm for
the chemical labeling and immunolabeling, respectively (Figure 6E). Although direct comparison of the
distances from these labels to the respective tags is not possible because the exact tag positions are
unknown, the variance of the measured distances is significantly smaller for 13-4Zn(II) than for anti-
FLAG antibody ($F_{277, 146} = 2.0, p < 0.001$), indicating higher resolution of the chemical labeling method
than the immunolabeling method (Figure 6F).

Conclusion
In summary, we have achieved EM detection of GPCR by chemical labeling using a reactive peptide tag-
probe pair. Rational design of the highly reactive α-helical peptide tag and the fine-tuning of probe reac-
tivity enabled the specific cysteine conjugation of the tag-fused B2R protein on cell surface. EM detection
using the tag-probe pair was successfully applied to determine the localization of B2R receptor on cell sur-
face with a high labeling specificity. Furthermore, the probe directly conjugated with a 1.4-nm gold particle
enabled the detection of the membrane proteins with a few times higher labeling efficiency and significantly higher spatial resolution than that of the antibody-mediated labeling, revealing high-density nano-clusters of proteins. EM detection methods for in-cell proteins using genetically encoded peroxidases have been developed in recent years (Shu et al., 2011; Martell et al., 2012; Hainfeld and Powell, 2000). Despite their usefulness, these methods are hardly applicable to single-protein detection since they have been devised for EM contrast imaging based on OsO4 staining in combination with oxidative diaminobenzidine (DAB) polymerization. To the best of our knowledge, the research presented herein is the first example of high-resolution single-protein detection by EM utilizing a chemical labeling. The use of our labeling method is currently limited to cell surface proteins. Nevertheless, this method can be widely used for EM analysis of membrane proteins on replicas in combination with SDS-FRL. We envision further application of the chemical labeling approach to reveal subunit composition of single-protein complexes on cell surface in combination with other tag-probe pairs (Uchinomiya et al., 2013).

Limitations of the Study
In our study, we demonstrate higher efficiency and resolution of the newly developed chemical labeling method compared with the common immunolabeling methods at the EM level using HEK cells expressing tagged B2R. Accurate evaluation of labeling resolution, however, requires understanding of the exact molecular structure of the tagged receptor. Since background and labeling conditions can be different between cell culture and various tissue environments, usefulness of the reported reactive peptide tag-probe pair needs further verification in more complex sample preparations.
METHODS
All methods can be found in the accompanying Transparent Methods supplemental file.

SUPPLEMENTAL INFORMATION

Scale bars, 200 nm.
Transparent Methods

Circular Dichroism (CD) Measurement. Aqueous solution of the zinc complex was added to a solution of the peptide (50 µM) in 10 mM borate buffer (pH 8.0). CD spectrum was measured at rt in a quartz cell (0.1 cm path length) using JASCO J-720W spectropolarimeter. The data of each sample was collected by 5 scans (scan range; 350 ~ 190 nm, scan speed; 50 nm•min⁻¹) and averaged to give CD spectrum.

Isothermal Titration Calorimetry (ITC) Measurement. ITC titration was performed with isothermal titration calorimeter (Malvern) at 298 K. Solution of peptide-c (6.0 mM) in buffer solution (50 mM HEPES, 100 mM NaCl, pH 7.2) was injected stepwise (5 µL x 48 times) to solution of 1-2Zn(II) (50 µM) in the same solvent system. The measured heat flow was recorded as function of time and converted into enthalpies (ΔH) by integration of the appropriate reaction peaks. Dilution effects were corrected by subtracting heat flow of blank experiment upon injection of the HEPES buffer under identical experimental conditions. The binding parameters (Kapp, ΔH, ΔS, n) were evaluated by applying one site model using the software Origin (Malvern).

Evaluation of Binding Constant. In a quartz cell, peptide-b (0.05 µM, final concentration) dissolved in 3 mL buffer (50 mM HEPES 100 mM NaCl, pH 7.2) was titrated with a freshly prepared aqueous solution of 2-4Zn(II) using a micro syringe at 25 °C. The fluorescence spectrum was measured (λex = 410 nm) using Perkin-Elmer LS55 spectrometer at each titration point. The change of the fluorescence intensity at 448 nm was analyzed by nonlinear least-square curve-fitting method to yield the apparent binding constant (Kapp, M⁻¹).

Kinetic Analysis of Nucleophilic Reaction of Peptide with mCBI. 10 µL of stock solution of mCBI (10 mM in DMSO) was added to a solution of peptide (4 µM) in 0.8 mL of buffer (50 mM HEPES 100 mM NaCl, pH 7.2, degassed under reduced pressure and charged with nitrogen before use) in the presence or absence of 2-4Zn(II) (14 µM). The fluorescence emission at 486 nm was continuously monitored by Perkin-Elmer LS55 spectrometer (λex = 396 nm) at 37 °C. The emission change was analyzed by nonlinear least-square curve-fitting method to yield the first-order reaction constant (k, sec⁻¹). For evaluation of pKₐ value of the cysteine residue, initial reaction rate of fluorescence change (V₀, ΔF, min⁻¹) were measured under the different pH
conditions in universal pH buffer (5 mM CHES-5 mM HEPES-5 mM MES, degassed under reduced pressure and charged with nitrogen before use) at 37 °C. The change of the initial rate over the pH range was analyzed by nonlinear curve-fitting method according to Henderson-Hasselbalch equation to yield $pK_a$ value.

**Kinetic Analysis of Cysteine Conjugation of Peptide with Zinc Complex.** Peptide (50 µM) and zinc complex (60 µM) was dissolved in 200 L of buffer solution (50 mM HEPES 100 mM NaCl, pH 7.2, degassed under reduced pressure and charged with nitrogen before use) and incubated at 37 °C in a plastic tube. Aliquot of the solution (20 µL) was sampled at appropriate times and mixed with 6 µL of inorganic pyrophosphate solution (10 mM in water) to quench the reaction followed by being kept at -20 °C. The thawed samples were mixed with 4 µL of mCBI (5 mM in DMSO) and incubated at 37 °C for 1 h in a dark. The solution (18µL) was diluted with a 582 µL of buffer solution (50 mM HEPES 100 mM NaCl, pH 7.2), and the fluorescence was measured ($\lambda_{ex} = 396$ nm) in a quartz cell using Perkin-Elmer LS55 spectrometer. The fluorescence change ($\lambda_{em} = 486$ nm) was analyzed by nonlinear least-square curve-fitting method according to second-order equation to yield half-reaction time ($t_{1/2}$, h).

**Fluorescence Detection of Covalent Labeling of Tag-fused MBP.** A solution of helixD2-tag-fused MBP (1 µM) or CH6 tag-fused MBP (1 µM) in 50 mM HEPES, 100 mM NaCl, 20 µM TCEP, pH 7.2 (degassed under reduced pressure and charged with nitrogen before use) was mixed with $10^{-4}$Zn(II) (10 µM, final concentration), and the mixture was incubated in a plastic tube at 37 °C. Aliquot of the solution (8 µL) was sampled at the appropriate times and mixed with 2 µL inorganic pyrophosphate solution (10 mM in water) followed by being kept at -20 °C. After thawing, the samples were mixed with 5x sampling buffer and heated at 95 °C for 2 min followed by being applied to SDS-PAGE. In-gel fluorescence and CBB analyses were performed with LAS-4000 lumino image analyzer (FUJIFILM) by EPI (460 nm excitation, Y515Di filter) and DIA-W mode, respectively.

**Cell Culture and B2R Expression in HEK293 Cells.** HEK293 cells were cultured in high glucose DMEM supplemented with 10% fetal bovine serum (FBS), penicillin (100 units/mL), streptomycin (100 µg/mL) and amphotericin B (250 ng/mL). Cells were maintained at 37 °C in humidified atmosphere of 5% CO$_2$ in air. Subculture was performed every 3-4 days from subconfluent (< 80%) cultures using trypsin-EDTA solution. Transfection of the expression
vector for B2R was carried out in a 35 mm glass-bottomed dish (Iwaki) using Lipofectamine LTX (Invitrogen) according to the general procedure. The cells were subjected to labeling experiment after 48 h of the transfection.

**Fluorescence Imaging of Tag-fused B2R.** In a glass bottom dish, HEK293 cells (~ 1 x 10^6) transiently expressing helixD2-tag fused B2R or CH6 tag-fused B2R were incubated in non-serum Dulbecco’s modified Eagle medium (DMEM) containing 2-deoxy-D-glucose (10mM) and sodium azide (6 mM) for 30 min at 37 °C in CO2 incubator. After removal of DMEM, cells were treated with TCEP (1 mM) for 10 min at rt in 1 mL HEPES-buffered saline (HBS, containing 107 mM NaCl, 6 mM KCl, 1.2 mM MgSO4, 2 mM CaCl2, 11.5 mM glucose, 10 mM 2-deoxy-D-glucose, 6 mM sodium azide 20 mM HEPES, adjusted to pH 7.4 with NaOH). TCEP solution was removed and then cells were treated with 10-4Zn(II) (4 µM, final concentration) for 30 min in HBS containing 2-deoxy-D-glucose (10 mM) and sodium azide (6 mM) at 37 °C. Cells were washed three times with HBS containing 2 mM pyrophosphate (PPI) (1 mL) to remove unreacted 10-4Zn(II). HBS containing Cy5-appended B2R antagonist peptide (0.4 µM) was added and cells were analyzed by confocal laser scanning microscope (Zeiss, LSM700) using appropriate laser and emission filter settings for Oregon Green 488 (λ_ex =488 nm, λ_em = 490-555 nm) and Cy5 (λ_ex = 639 nm, λ_em > 640 nm).

**Evaluation of Non-specific Labeling Property of Probe.** In a glass bottom dish, HEK293 cells (~ 1 x 10^6) were incubated in non-serum DMEM containing 2-deoxy-D-glucose (10mM) and sodium azide (6 mM) for 30 min at 37 °C in a CO2 incubator. After removal of DMEM, cells were treated with TCEP (1 mM) for 10 min at rt in 1 mL HEPES-buffered saline. TCEP solution was removed and then cells were treated with 10-4Zn(II) or 11-4Zn(II) (4 µM, final concentration) for 10 or 30 min in HBS containing 2-deoxy-D-glucose (10 mM) and sodium azide (6 mM) at 37 °C. After washing three times with HBS containing 2 mM PPI (1 mL), the cells were fixed by treatment with PBS (100 µL) containing 4% paraformaldehyde, 0.2% glutaraldehyde, and 2 mM PPI for 10 min with gentle shaking (80 rpm) at rt. The fixed cells were washed three times with HBS containing 0.1% Triton-X and 2 mM pyrophosphate (PPI) (1 mL) by gentle shaking (80 rpm) for 10 min at rt. The cells were immersed in HBS (100 µL) and the fluorescence on the cell surfaces were detected by confocal laser scanning microscope (Leica, TCS SP8) equipped with HyD detector with a high laser power (1%) for Oregon Green 488 (λ_ex
=488 nm). The fluorescence image was analyzed by ImageJ software (National Institutes of Health) to obtain the fluorescence intensity per area on the cell surface.

**EM Detection of B2R in Freeze-fracture Replicas.** HEK293T cells (ca. \(2 \times 10^7\) cells) transiently expressing helixD2-B2R-EGFP, GluA2 (for negative control) or co-expressing helixD2-B2R-EGFP and GluA2 were washed with HEPES-buffered saline (HBS), and treated with 2 mM TCEP in HBS (1 mL) for 10 min at 37 °C. After removal of TCEP solution, the cells were treated with 3 \(\mu\)M \(\text{^{12-4}Zn(II)}\) in HBS for 30 min at 37 °C, or with 3 \(\mu\)M \(\text{^{13-4}Zn(II)}\) in HBS for 2 h at 37 °C. After washing with HBS containing 2 mM PPI, the cells labeled with \(\text{^{12-4}Zn(II)}\) were incubated with 1.4-nm gold particle-conjugated streptavidin (Nanoprobes) for 1 h at 37 °C. For estimation of chemical labeling density in unfixed cells, cells were fixed after chemical labeling (after washing out the \(\text{^{13-4}Zn(II)}\) with PPI) and for estimation of chemical labeling density in fixed cells, fixation was performed before chemical labeling (before HBS washing). Fixation was done with 2% paraformaldehyde in phosphate-buffered saline (PBS) for 15 min at RT. The cells were harvested by scraping, collected by centrifugation (100g, 5 min), and the cell pellet was sandwiched between gold carriers for high-pressure freezing (HPM010, Bal-Tec). The frozen pellet was then fractured into two parts at \(-120 °C\) and replicated by depositions of 30 nm carbon layer using freeze-fracture replica machine (BAF 060, Bal-Tec). After thawing, the replicas were washed with 2.5% SDS, 20% sucrose, and 15 mM Tris-HCl (pH 8.3) under the following conditions: 48 h at 60 °C for labeling with \(\text{^{13-4}Zn(II)}\); 3 d at 60 °C for labeling of pre-fixed cells with \(\text{^{12-4}Zn(II)}\); and 18 h at 60 °C for labeling with \(\text{^{12-4}Zn(II)}\).

For EM detection of 1.4-nm gold particle-conjugated streptavidin, the replicas were treated with reagents from a silver intensification kit (HQ Silver, Nanoprobes). For immunolabeling, the replicas were treated with mouse anti-GFP (CLONTECH), rabbit anti-FLAG (Sigma-Aldrich) or rabbit anti-GluA2 antibodies (Figure S9) for 48 h at 15 °C, followed by staining with anti-mouse secondary antibody conjugated with 5-nm gold particles or anti-rabbit secondary antibody conjugated with 10-nm gold particles (British Biocell International). The silver-intensified replicas were analyzed by EM using Tecnai 10/12 transmission electron microscope (FEI); those without silver intensification were analyzed by JEM-2800 scanning transmission electron microscope (JEOL) in dark field mode. For quantitative analysis of particle distribution, we used GPDQ software (Wickman et al., 2018) to calculate the density and NND of particles, particle number per cluster, and cluster area. For the definition of clusters of particles, we used 3 particles as a minimum number and mean + 2SD (Miki et al., 2017; Wickman et al., 2018) of
fitted peaks of NND (Figure 5I) as a maximum distance allowed (6 + 3×2 = 12 nm for chemical labeling, 22 + 10×2 = 42 nm for immunolabeling).

**EM Detection of B2R in Embedded Ultrathin Sections.** HEK293 cells (ca. 2 × 10⁷ cells) transiently expressing helixD2-B2R-EGFP cultured on a coverslip were treated with 2 mM TCEP in HBS for 10 min at 37 °C. After removal of the solution, the cells were treated with 3 μM 13-4Zn(II) for 2 h at 37 °C, and washed with 2 mM Ppi in HBS. The cells were then fixed in PBS containing 4% paraformaldehyde and 0.05% glutaraldehyde for 10 min at rt. After 3-6 min silver intensification, the cells were treated with 0.2% OsO₄ in PBS for 20 min, counterstained with 0.25% uranyl acetate overnight at 4 °C, dehydrated in ascending series of EtOH and propylene oxide, and embedded in Durcupan (Sigma-Aldrich). Ultrathin sections (70-μm thick) prepared using ultramicrotome (Leica Ultracut UCT, Leica) were counterstained with lead citrate and uranyl acetate, and analyzed by Tecnai 10 transmission electron microscope (FEI). For immunolabeling of the FLAG tag, HEK293 cells were fixed by 4% paraformaldehyde and 0.05% glutaraldehyde in PBS for 10 min at rt. After blocking with 10% normal goat serum and 2% bovine serum albumin in Tris-buffered saline (TBS), the cells were treated with anti-FLAG antibody (Sigma-Aldrich) followed by anti-mouse secondary antibody conjugated with 1.4-nm gold particles (Nanoprobes). After 3-6 min silver intensification, the cells were treated, sectioned and observed in the same way as described above. To measure the distance between gold particles and cell membrane, we first tilted the ultrathin sections to obtain perpendicular views of lipid bilayer (Figure 6B and 6D). We discarded the particles if it was not possible to obtain perpendicular views. Then, the distance between the center of silver-intensified gold particles and the midpoint of plasma membrane was determined by ImageJ v1.51 software (National Institutes of Health).
Construction of expression-vectors of the tag-fused maltose binding protein (MBP)

DNA encoding helixD2-tag (KKCPYSAADAAAADAAADAAAD) was introduced into the pMAL-c2X vector (New England BioLabs) encoding D4-tag fused MBP (Nonaka et al., 2010) by inverse polymerase chain reaction (PCR). After digestion of the template plasmid by the treatment with Dpn I, 5'-termini of the PCR product were phosphorylated by T4 polynucleotide kinase and then cyclized by DNA ligase to give the vector encoding helixD2-tag fused MBP. The DNA sequence of the vectors was confirmed by 3130xI Genetic Analyzer (Applied Biosystems).

Expression and purification of tag-fused MBP

pMAL-c2X vector encoding helixD2-tag fused MBP was transformed into T7 Expression lysY/I competent E. coli (New England BioLabs). Single colony was cultured at 37 °C in 2YT media (200 mL) containing ampicillin (100 mg/L) at 37 °C until optical density (OD) at 600 nm increased to 0.6 and further grown at 37 °C for 6 h with IPTG induction (1 mM final conc.). Cells were spun down for 10 min at 13,500 rpm and re-suspended in equilibrium buffer (20 mM Tris–HCl, 200 mM NaCl, 1mM EDTA, 1mM DTT, pH 8.0) and then lysed by sonication (150 shots x 2) on ice. Insoluble materials were removed by centrifugation (13,500 rpm, 10 min) and supernatant was applied to a MBP Trap affinity column (GE Healthcare). Column was washed with equilibrium buffer (x2) and then MBP was eluted by elusion buffer (20 mM Tris–HCl, 200 mM NaCl, 10 mM maltose, pH 8.0). Purity of MBP in fractions was checked by SDS-PAGE. Concentration of purified MBP was determined by the UV absorbance at 280 nm using the calculated extinction coefficient (ε280nm = 69,330 M⁻¹cm⁻¹). MBP solution was kept at 4 °C in the presence of 1 mM TCEP.

Construction of vectors of tag-fused B2R receptor

DNA encoding helixD2-tag (KKCPYSAADAAAADAAADAAAD) or CH6 tag inserted into pClneo plasmid encoding α7-D4-B2R vector (Nonaka et al., 2010) by inverse polymerase chain reaction (PCR). After digestion of template plasmid by the treatment with Dpn I, 5'-termini of the PCR product were phosphorylated by T4 polynucleotide kinase and then cyclized by DNA ligase to give the vector encoding α7-helixD4-B2R or α7-CH6-B2R. DNA sequences were confirmed by 3130xI Genetic Analyzer (Applied Biosystems).
Solid-Phase Peptide Synthesis

Peptides except for peptide-e were synthesized by solid-phase peptide synthesis using standard Fmoc-based coupling chemistry. Coupling reactions (0.2 mmol scale) were performed using 4 equiv of amino acid, 4 equiv of HOBr and 4 equiv of HBTU on Rink Amide MBHA Resin LL (0.2 mmol, 0.38 mmol/g, Merck Millipore). N-terminal was acetylated by treatment with 20 equiv of Ac₂O in NMP. Peptide cleavage and deprotection were carried out by treatment of resin with TFA / H₂O / triisopropylsilane (95 : 2.5 : 2.5) for 3 h at rt. The crude peptide was collected by precipitation in tert-butyl methyl ether and purified by reverse-phase HPLC (column; YMC-pack ODS-A, 20 x 250 mm) using CH₃CN (0.1% TFA) / H₂O (0.1% TFA) solvent system with a linear gradient mode. Typical HPLC conditions are as follows; 5 / 95 (0 min) → 5 / 95 (10 min) → 40 / 60 (50 min), flow rate 9.9 mL/min, UV detection at 220 nm. Purified peptide was lyophilized and stored in a refrigerator (-30 °C).

MALDI-TOF-MS analysis (CHCA)
peptide-a: calcd for C₅₇H₈₀N₁₆O₂₅ (MW; 1392.6), found 1416.3 [M+Na]^+.
peptide-b¹: calcd for C₅₃H₅₇N₁₅O₂₄ (MW; 1357.6), found 1358.7 [M+H]^+.  
peptide-d: calcd for C₆₈H₉₀N₂₀O₂₀S (MW; 1694.7), found 1694.3 [M]^+.
peptide-e: calcd for C₆₉H₁₀₂N₂₀O₂₅S (MW; 1706.7), found 1706.8 [M]^+.
peptide-f: calcd for C₇₀H₁₀₄N₂₀O₂₉S (MW; 1720.7), found 1719.8 [M-H]:
peptide-g: calcd for C₇₁H₁₂₀N₂₂O₃₀S (MW; 1864.8), found 1864.2 [M-H]:
peptide-h: calcd for C₇₇H₁₂₈N₂₆O₃₀S (MW; 1920.8), found 1920.2 [M-H]:
peptide-i: calcd for C₆₈H₈₅N₁₅O₃₆S (MW; 1785.6), found 1783.1 [M-H]:
peptide-j: calcd for C₈₀H₁₂₃N₂₃O₃₁S (MW; 1935.9), found 1937.0 [M]:
peptide-k: calcd for C₈₃H₁₃₈N₂₄O₃₂S (MW; 2006.9), found 2005.5. [M-H]:
¹) peptide-b1 is a peptide that lacks 7-hydroxycumarin from peptide-b.

Conjugation of peptide-b1 with 7-hydroxycumarine

A solution of the peptide-b1 (3 mg, 2.21 µmol), 7-hydroxycumarine succinimidyl ester (3.3 mg, 11.1 µmol) and DIEA (438 µL, 1.16 mmol) in dry DMF (2 mL) was stirred overnight at rt. H₂O (1.5 mL) was added, the solution was stirred for 1 h at rt. Purification was conducted by HPLC (column; YMC-Actus Triart C18, 20 x 250 mm) using CH₃CN (0.1% TFA) / H₂O (0.1%
TFA) solvent system with a linear gradient mode. The collected fractions were lyophilized to give peptide-b.

HPLC conditions: column; YMC-Actus Triart C18, 250 x 20 mm, mobile phase; CH$_3$CN (containing 0.1% TFA) / H$_2$O (containing 0.1% TFA) = 5 / 95(0-10 min) → 60 / 40 (linear gradient over 50 min), MALDI-TOF-MS: calcd for C$_{64}$H$_{91}$N$_{17}$O$_{28}$ 1545.6, found 1544.5 [M-H].
General Materials and Methods for Organic Synthesis

Unless otherwise noted, chemical reagents were purchased from commercial suppliers (Tokyo Chemical Industry (TCI), Wako Pure Chemical Industries, Watanabe Chemical Industries, and Sigma-Aldrich) and used without further purification. $^1$H-NMR spectra were recorded using Varian UNITY-400 (400 MHz) spectrometer, and chemical shifts (δ, ppm) were referenced to residual solvent peak. ESI and MALDI-TOF mass spectra were measured using Bruker micrOTOF II and Bruker autoflex III spectrometer, respectively. HPLC purification was conducted with Hitachi L-7100. Compound 6, 15 and 18 were synthesized according to the previous report (Nonaka et al., 2010).

Synthesis of 16

To a solution of Boc-βAla-OH (185 mg, 0.98 mmol) in dry DMF (5 mL) was added WSC·HCl (188 mg, 0.98 mmol), HOBr·H₂O (150 mg, 0.98 mmol), DIEA (391 μL, 2.4 mmol) and 15 (433 mg, 0.70 mmol). The solution was stirred overnight at rt. After dilution with AcOEt, the mixture was washed with saturated NaHCO₃ and brine followed by drying over Na₂SO₄. After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO₂ (CH₂Cl₂ : MeOH : NH₃ = 400 : 10 : 1 → 300 : 10 : 1) to give 16 (410 mg, 73%) as a colorless amorphous powder.

$^1$H-NMR(400 MHz, CDCl₃): δ 10.99 (1H, br), 8.50 (4H, s), 7.56 (4H, t, J = 7.4 Hz), 7.42 (4H, d, J = 7.6 Hz), 7.09 (4H, t, J = 5.8 Hz), 6.94 (2H, s), 6.71 (1H, d, J = 8.0 Hz), 5.26 (1H, br), 4.74
(1H, m), 3.83 (8H, s), 3.75 (4H, s), 3.65 (3H, s), 3.25 (2H, d, J = 5.6 Hz), 3.01 (2H, t, J = 8.8 Hz), 2.21 (2H, m), 1.37 (9H, s). ESI-TOF-MS m/z [M + Na]⁺ calcd for C₄₄H₅₂N₈O₆Na 811.39; Found 811.39.

Synthesis of 17

To an ice-cooled solution of 16 (410 mg, 510 µmol) in CH₂Cl₂ (2.5 mL) was added dropwise TFA (2.5 mL) and the solution was stirred for 1 h at rt. The solvent was removed in vacuo and the residue was dissolved in H₂O. The mixture was neutralized with aq. NH₃ on ice-cooling and then extracted with CH₂Cl₂. The organic layer was washed with brine followed by drying over Na₂SO₄. The solution was concentrated by evaporation to give 17 (330 mg, 92%) as a colorless amorphous powder.

¹H-NMR (400 MHz, CDCl₃) : δ 10.90 (1H, br), 8.47 (4H, s), 8.25 (1H, br), 7.51 (4H, t, J = 7.4 Hz), 7.30 (4H, d, J = 7.6 Hz), 7.07 (4H, t, J = 6.0 Hz), 6.93 (2H, s), 4.66 (1H, br), 3.86 (4H, m), 3.65 (11H, m), 2.93 (4H, m), 2.59 (1H, br), 2.33 (1H, m). ESI-TOF-MS m/z [M + Na]⁺ calcd for C₃₉H₄₅N₈O₄Na 689.36; Found 689.36.

Synthesis of 2

To a solution of 18 (430 mg, 0.61 mmol) in dry DMF (5 mL) was added WSCI•HCl (115 mg, 0.61 mmol), HOBt•H₂O (93 mg, 0.61 mmol), DIEA (246 µL, 1.41 mmol) and 17 (330 mg, 0.47 mmol). The solution was stirred overnight at rt. After dilution with AcOEt, the mixture was washed with saturated NaHCO₃ and brine followed by drying over Na₂SO₄. After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO₂ (CHCl₃ : MeOH : NH₃ = 300 : 10 : 1→200 : 10 : 1) to give 2 (450 mg, 70%) as a colorless amorphous powder.

¹H-NMR(400 MHz, CDCl₃): δ 10.95 (2H, br), 8.47 (8H, s), 7.56 (8H, m), 7.40 (8H, t, J = 6.4 Hz), 7.14 (1H, br), 7.04 (10H, m), 6.95 (2H, s), 5.36 (1H, br), 4.65 (1H, m), 4.23 (1H, br), 3.73 (25H, m), 3.57 (3H, s), 3.46 (1H, s), 3.16 (1H, br), 2.91 (4H, m), 2.11 (2H, m), 1.24 (9H, s). ESI-TOF-MS 1396.66 [M + H⁺]. ¹³C NMR (125 MHz, CDCl₃) δ 173.1, 172.1, 172.0, 159.1, 155.9, 155.7, 155.1, 155.0, 149.0, 136.9, 130.4, 130.3, 126.5, 126.0, 124.0, 123.3, 123.3, 122.2 x 2, 79.7, 59.7, 56.4, 54.9, 54.8, 54.1, 52.3, 37.9, 36.5, 35.9, 35.8, 28.3. ESI-TOF-MS m/z [M + Na]⁺ calcd for C₇₀H₆₇N₁₃O₈Na 1396.68; Found 1396.66.
Synthesis of 3

To an ice-cooled solution of cinnamic acid (12 mg, 81 μmol) in dry DMF (1.5 mL) was added triethylamine (11 μL, 81 μmol), Py-BOP (36 mg, 81 μmol) and 15 (50 mg, 81 μmol). The solution was stirred for 3 h at rt. After dilution with AcOEt, the mixture was washed with saturated NaHCO₃ and brine followed by drying over Na₂SO₄. After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO₂(CHCl₃ : MeOH : NH₃ = 400 : 10 : 1) to give 3 (52 mg, 86%) as a colorless amorphous powder.

1H-NMR(400 MHz, DMSO-d₆): δ 10.94 (1H, s), 8.49-8.45 (5H, m), 7.68 (4H, t, J = 7.2 Hz), 7.44-7.32 (9H, m), 7.20 (4H, t, J = 6.0 Hz), 7.05 (2H, s), 6.65 (1H, d, J = 16 Hz), 4.6 (1H, q, J = 13.6 Hz, 6.4 Hz), 3.73 (8H, s), 3.64 (4H, s), 3.52 (3H, s), 2.98-2.85 (1H, m). ESI-TOF-MS m/z [M + H]⁺ calcd for C₄₅H₄₆N₇O₇ 748.36; Found 748.38.

Synthesis of 4

To an ice-cooled solution of crotonic acid (4.1 mg, 48 μmol) in dry DMF (1.5 mL) was added a mixture of triethylamine (6.7 μL, 48 μmol), Py-BOP (22 mg, 48 μmol) and 15 (30 mg, 48 μmol). The solution was stirred for 28 h at rt. After dilution with AcOEt, the mixture was washed with saturated NaHCO₃ and brine followed by drying over Na₂SO₄. After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO₂(CHCl₃ : MeOH : NH₃ = 250 : 10 : 1) to give a pale yellow oil (24 mg). This oil was further purified by column chromatography on SiO₂(CHCl₃ : MeOH : NH₃ = 350 : 10 : 1) to give 4 (7 mg, 21%) as a pale yellow oil.

1H-NMR(400 MHz, CDCl₃): δ 10.94 (1H, br), 8.52 (4H, d, J = 4.8 Hz), 7.60 (4H, t, J = 7.6 Hz), 7.44 (4H, d, J = 8.0 Hz), 7.11 (4H, t, J = 6.4 Hz), 6.97 (2H, s), 6.80-6.74 (1H, m), 6.41 (1H, d, J = 7.6 Hz), 4.86 (1H, q, J = 13.6 Hz, 7.6 Hz), 3.85 (8H, s), 3.76 (4H, s), 3.65 (3H, s), 3.05 (2H, d, J = 5.2 Hz), 1.68 (3H, d, J = 6.8 Hz). ESI-TOF-MS m/z [M + H]⁺ calcd for C₄₀H₄₄N₇O₄ 686.34; Found 686.36.
Synthesis of 5

To an ice-cooled solution of 4-(dimethylamino)-2-butenoic acid hydrochloride (13 mg, 80 \( \mu \text{mol} \)) in dry DMF (1.5 mL) was added DIEA (44 \( \mu \text{L}, 240 \mu \text{mol} \)), Py-BOP (36 mg, 80 \( \mu \text{mol} \)) and 15 (50 mg, 80 \( \mu \text{mol} \)). The solution was stirred for 44 h at rt. After dilution with AcOEt, the mixture was washed with saturated NaHCO\(_3\) and brine followed by drying over Na\(_2\)SO\(_4\). After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO\(_2\) (CHCl\(_3\) : MeOH : NH\(_3\) = 300 : 10 : 1 → 150 : 10 : 1) to give 5 (56 mg, 95%) as a pale yellow oil.

\(^1\)H-NMR (400 MHz, CDCl\(_3\)) : \( \delta \) 8.52 (4H, d, \( J = 4.8 \) Hz), 7.58 (4H, t, \( J = 8.0 \) Hz), 7.44 (4H, d, \( J = 8.0 \) Hz), 7.10 (4H, t, \( J = 6.0 \) Hz), 6.97 (2H, s), 6.80-6.74 (1H, m), 6.57 (1H, d, \( J = 7.6 \) Hz), 4.86 (1H, q, \( J = 13.2 \) Hz, 5.6 Hz), 3.84 (8H, s), 3.76 (4H, s), 3.65 (3H, s), 3.05 (2H, d, \( J = 6.0 \) Hz), 2.89 (2H, m), 2.14 (6H, s). ESI-TOF-MS m/z [M + H]\(^+\) calcd for C\(_{42}\)H\(_{49}\)N\(_8\)O\(_4\) 729.39; Found 729.40.

Synthesis of 19

To an ice-cooled solution of 2 (300 mg, 0.24 mmol) in dry CH\(_2\)Cl\(_2\) (2.0 mL) was added dropwise TFA (2.5 mL) and the solution was stirred for 1 h at rt. After removal of the solvent in vacuo, the residue was dissolved in H\(_2\)O. The mixture was neutralized with aqueous NH\(_3\) on ice-cooling and then extracted with CH\(_2\)Cl\(_2\). The organic layer was washed with brine followed by drying over Na\(_2\)SO\(_4\). The solution was concentrated by evaporation to give 19 (250 mg, 90%) as a colorless amorphous powder.

\(^1\)H-NMR (400 MHz, CDCl\(_3\)) : \( \delta \) 10.96 (2H, br), 8.50 (8H, t, \( J = 2.4 \) Hz), 7.76 (1H, m), 7.59 (8H, t, \( J = 7.6 \) Hz), 7.45 (8H, t, \( J = 8.0 \) Hz), 7.10 (8H, t, \( J = 6.0 \) Hz), 7.03 (2H, s), 6.97 (2H, s), 4.77 (1H, dd, \( J = 6.8 \) Hz), 3.84 (16H, s), 3.80-3.73 (9H, m), 3.62 (3H, s), 3.44-3.35 (4H, m), 3.11-2.98
(4H, m), 2.56-2.50 (1H, m), 2.25-2.24 (2H, m). ESI-TOF-MS m/z [M + H]^+ calcd for C$_{74}$H$_{80}$N$_{15}$O$_6$ 1274.64; Found 1274.66.

Synthesis of 7

To an ice-cooled solution of 4-(dimethylamino)-2-butenoic acid hydrochloride (3.8 mg, 25 µmol) in dry DMF (1.0 mL) was added DIEA (12 µL, 63 µmol), Py-BOP (12 mg, 24 µmol) and 19 (20 mg, 16 µmol). The solution was stirred for 38 h at rt. After dilution with AcOEt, the solution was washed with saturated NaHCO$_3$ and brine followed by drying over Na$_2$SO$_4$. After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO$_2$ (CHCl$_3$ : MeOH : NH$_3$ = 400 : 4 : 1→180 : 30 : 1) to give 7 (12 mg, 53%) as a colorless oil.

$^1$H-NMR (400 MHz, DMSO-d$_6$): δ 10.93 (1H, s), 10.81 (1H, s), 8.45 (8H, d, $J$ = 4.8 Hz), 8.30 (1H, d, $J$ = 9.2 Hz), 8.12 (1H, d, $J$ = 8.4 Hz), 7.98 (1H, m), 7.68 (8H, t, $J$ = 7.2 Hz), 7.42 (8H, d, $J$ = 7.6 Hz), 7.20 (8H, dd, $J$ = 1.4 Hz, 6.2 Hz), 7.03 (2H, s), 6.99 (2H, s), 6.36-6.33 (1H, m), 5.96 (1H, d, $J$ = 15.6 Hz), 4.50-4.40 (2H, m), 3.71 (16H, d, $J$ = 8.4 Hz), 3.61 (8H, d, $J$ = 11.2 Hz), 3.42 (3H, s), 3.15-3.14 (4H, m), 2.88-2.62 (8H, m), 2.24-2.14 (4H, m), 1.93 (6H, s). ESI-TOF-MS m/z [M + H]^+ calcd for C$_{80}$H$_{19}$N$_{16}$O$_7$ 1385.71; Found 1385.72.
Synthesis of \textbf{21}

To an ice-cooled solution of \textbf{20} (13 mg, 47 µmol) in dry DMF (1.5 mL) was added DIEA (23 µL, 126 µmol), Py-BOP (25 mg, 47 µmol) and \textbf{19} (40 mg, 31 µmol) and the solution was stirred for 13 h at rt. After dilution with AcOEt, the solution was washed with saturated NaHCO$_3$ and brine followed by drying over Na$_2$SO$_4$. After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO$_2$ (CHCl$_3$ : MeOH : NH$_3$ = 400 : 4 : 1 → 160 : 20 : 1) to give \textbf{21} (44 mg, 33%) as a colorless oil. This material contained a small amount of impurities but was used for the next reaction without further purification.

$^1$H-NMR (400 MHz, DMSO-$d_6$): $\delta$ 10.93 (1H, s), 10.87 (1H, s), 8.45 (8H, d, $J = 3.6$ Hz), 8.31 (1H, d, $J = 7.6$ Hz), 8.06 (1H, t), 7.68 (8H, t, $J = 7.6$ Hz), 7.50 (1H, d, $J = 8.0$ Hz), 7.42 (8H, d, $J = 7.6$ Hz), 7.20 (8H, dd, $J = 1.6$ Hz, 6.0 Hz), 6.98 (4H, d, $J = 2.4$ Hz), 6.73 (1H, t), 4.51-4.39 (2H, m), 3.73 (16H, s), 3.63 (8H, d, $J = 2.8$ Hz), 3.42 (3H, s), 3.15 (4H, m), 2.89-2.66 (6H, m), 2.31-2.07 (4H, m), 1.32 (9H, s). ESI-TOF-MS $m/z$ [M + H]$^+$ calcd for C$_{85}$H$_{96}$N$_{16}$O$_{15}$ 1520.77; Found 1520.78.
Synthesis of 22

To an ice-cooled solution of the crude 21 (43 mg) in CH₂Cl₂ (1 mL) was added dropwise TFA (1 mL) and the solution was stirred for 1 h at rt. After removal of the solvent in vacuo, the residue was dissolved in H₂O. The mixture was neutralized with aq. NH₃ on ice-cooling and extracted with CH₂Cl₂ (x2). The organic layer was washed with brine followed by drying over Na₂SO₄. The solution was concentrated by evaporation to give 22 (41 mg, quant) as a colorless oil. This material contained a small amount of impurities but was used for the next reaction without further purification.

¹H-NMR (400 MHz, CDCl₃) : δ 11.03 (2H, br), 8.49 (8H, t, J = 5.6 Hz), 7.58 (8H, dd, J = 8.0 Hz, 11.6 Hz), 7.42 (8H, t, J = 7.2 Hz), 7.37 (1H, t, J = 7.2 Hz), 7.12-7.08 (8H, m), 7.02 (2H, s), 6.98 (2H, s), 4.64-4.57 (2H, m), 3.83 (16H, s), 3.77-3.71 (8H, m), 3.56 (3H, s), 3.55-3.46 (6H, m), 3.10-2.82 (8H, m), 2.20-2.04 (4H, m). ESI-TOF-MS m/z [M + H]⁺ calcd for C₈₀H₉₁N₁₆O₁₄ 1419.71; Found 1419.73.

Synthesis of 8

To an ice-cooled solution of 4-(dimethylamino)-2-butenoic acid hydrochloride (3.4 mg, 21 µmol) in dry DMF (1 mL) was added DIEA (10 µL, 56 µmol), Py-BOP (11 mg, 21 µmol) and the crude 22 (20 mg). The solution was stirred for 14.5 h at rt. After dilution with AcOEt, the solution was washed with saturated NaHCO₃ and brine followed by drying over Na₂SO₄. After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO₂ (CHCl₃ : MeOH : NH₃ = 400 : 4 : 1→200 : 4 : 1→180 : 30 : 1) to give 8 (7 mg, 33%) as a colorless oil.

¹H-NMR (400 MHz, DMSO-d₆) : δ 10.93 (1H, s), 10.88 (1H, s), 8.46 (8H, d, J = 3.6 Hz), 8.46 (8H, d, J = 3.6 Hz), 8.36 (1H, m), 8.20 (1H, m), 8.02 (1H, m), 7.68 (8H, t, J = 7.2 Hz), 7.52 (1H, d), 7.41 (8H, d, J = 8.0 Hz), 7.20 (8H, d, J = 7.6 Hz), 6.98 (4H, s), 6.52 (1H, m), 6.06 (1H, m), 4.56-4.38 (4H, m), 3.72-3.63 (26H, m), 3.42 (3H, s), 3.15 (4H, m), 2.90 (6H, m), 2.30-2.11 (4H, m), 2.06 (6H, s). ESI-TOF-MS m/z [M + H]⁺ calcd for C₈₆H₁₀₀N₁₇O₁₀ 1530.78; Found 1530.78.
Synthesis of 23

To an ice-cooled solution of 19 (20 mg, 13.6 µmol) in dry DMF (1 mL) was added WSCI•HCl (3.6 mg, 19 µmol), HOBt•H₂O (2.9 mg, 19 µmol), DIEA (12 µL, 75 µmol) and Boc-L-Pro (4 mg, 19 µmol). The solution was stirred for 13 h at rt. After dilution with AcOEt, the solution was washed with saturated NaHCO₃ and brine followed by drying over Na₂SO₄. After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO₂ (CHCl₃ : MeOH : NH₃ = 400 : 4 : 1 → 160 : 20 : 1) to give 23 (22 mg, 95%) as a colorless amorphous powder.

¹H-NMR (400 MHz, CDCl₃): δ 10.98 (2H, br), 8.49 (8H, d, J = 4.0 Hz), 7.58 (8H, dd, J = 8.0 Hz, 11.6 Hz), 7.45 (8H, t, J = 6.8 Hz), 7.12-7.08 (8H, m), 6.99 (4H, s), 6.77 (2H, m), 4.68-4.53 (2H, m), 4.11 (1H, m), 3.83-3.75 (24H, m), 3.57 (3H, s), 3.20-2.96 (10H, m), 2.22 (4H, m), 1.62 (9H, br). ESI-TOF-MS m/z [M + H]+ calcd for C₈₄H₉₅N₁₆O₁₄ 1472.75; Found 1472.75.

Synthesis of 24

To an ice-cooled solution of 23 (20 mg, 13.6 µmol) in CH₂Cl₂ (1 mL) was added dropwise TFA (1 mL) and the solution was stirred for 1 h at rt. After removal of the solvent in vacuo, the residue was dissolved in H₂O. The mixture was neutralized with aq. NH₃ on ice-cooling and extracted...

S24
with CH₂Cl₂. The organic layer was washed with brine followed by drying over Na₂SO₄. The solution was concentrated by evaporation to give 24 (24 mg, quant) as a colorless oil.

\(^1\)H-NMR (400 MHz, CDCl₃) : δ 10.95 (2H, br), 8.49 (8H, t, J = 3.2 Hz), 8.02 (1H, m), 7.58 (8H, dd, J = 7.2 Hz, 10.4 Hz), 7.45 (8H, t, J = 8.8 Hz), 7.37 (1H, t, J = 8.0 Hz), 7.10-7.02 (8H, m), 7.00 (5H, s), 4.63 (2H, dd, J = 5.2 Hz), 4.41 (2H, m), 4.11 (1H, m), 3.87-3.75 (24H, m), 3.60 (3H, s), 3.22-2.10 (14H, m). ESI-TOF-MS m/z [M + H]^+ calc'd for C₇₉H₆₇N₁₆O₁₁ 1371.69; Found 1371.70.

Synthesis of 9

To an ice-cooled solution of 4-(dimethylamino)-2-butenolic acid hydrochloride (3.4 mg, 21 µmol) in dry DMF (1 mL) was added a mixture of DIEA (10 µL, 56 µmol), Py-BOP (11 mg, 21 µmol) and 24 (22 mg, 14 µmol). The solution was stirred for 18 h at rt. After dilution with AcOEt, the solution was washed with saturated NaHCO₃ and brine followed by drying over Na₂SO₄. After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO₂ (CHCl₃: MeOH: NH₃ = 400 : 4 : 1→160 : 20 : 1) to give 9 (11 mg, 47%) as a colorless amorphous powder.

\(^1\)H-NMR (400 MHz, DMSO-d₆) : δ 10.94 (2H, d), 8.46 (8H, d), 8.30 (1H, d, J = 10 Hz), 7.79 (1H, m), 7.68 (8H, t, J = 7.6 Hz), 7.44 (8H, t, J = 8.0 Hz), 7.21 (8H, t, J = 5.6 Hz), 6.99 (4H, s), 6.58 (1H, m), 6.32 (1H, m), 4.41 (2H, m), 3.72 (16H, s), 3.64 (8H, s), 3.42 (3H, s), 3.18-2.78 (12H, m), 2.12 (6H, br), 1.87 (2H, m). ESI-TOF-MS m/z [M + H]^+ calc'd for C₈₅H₉₆N₁₇O₁₄ 1482.76; Found 1482.76.
Synthesis of 25

To an ice-cooled solution of 18 (1.0 g, 1.42 mmol) in dry DMF (6 mL) was added WSCI•HCl (355 mg, 1.85 mmol), HOBt•H₂O (283 mg, 1.85 mmol), DIEA (0.9 mL, 5.68 mmol) and H- β-Ala-OMe•HCl (258 mg, 1.85 mmol). The solution was stirred for 6 h at rt. After dilution with AcOEt, the solution was washed with saturated NaHCO₃ and brine followed by drying over Na₂SO₄. After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO₂ (CHCl₃ : MeOH : NH₃ = 300 : 10 : 1 → 200 : 10 : 1) to give 25 (953 mg, 85%) as a colorless amorphous powder.

1H-NMR (400 MHz, CDCl₃): δ 10.98 (1H, br), 8.54 (4H, d, J = 4.8 Hz), 7.60 (4H, t, J = 6.8 Hz), 7.45 (4H, d, J = 8.0 Hz), 7.12 (4H, t, J = 8.0 Hz), 7.04 (2H, s), 5.32 (1H, m), 4.30 (1H, m), 3.90-3.70 (12H, m), 3.46 (3H, s), 3.31-3.23 (2H, m), 3.02-2.97 (1H, m), 2.87-2.81 (1H, m), 2.34-2.17 (2H, m), 1.36 (9H, s). ESI-TOF-MS m/z [M + H]+ calcd for C₄₄H₅₃N₇O₆ 789.41; Found 789.41.

Synthesis of 26

To an ice-cooled solution of 25 (916 mg, 1.16 mmol) in MeOH-H₂O (18 : 5 (v/v), 23 mL) was added 5 N NaOH (696 L, 3.48 mmol) and the solution was stirred for 7 h at 0 °C. After dilution with water, the solution was washed with diethyl ether (x2). The pH was adjusted to 5 and extracted with CHCl₃ (x2). The organic phase was dried over Na₂SO₄ and concentrated in vacuo. The residue was washed with hexane-i-PrOH (1 : 1) to give 26 (804 mg, 89%) as a colorless amorphous powder.

1H-NMR (400 MHz, CDCl₃): δ 8.54 (4H, m), 7.70-7.52 (8H, m), 7.13 (4H, m), 7.01 (2H, s), 6.70 (1H, m), 5.55 (1H, m), 4.37 (1H, m), 4.00 (12H, m), 3.46 (1H, m), 3.26 (1H, m), 3.09-3.07 (1H, m).
m), 2.76-2.70 (1H, m), 2.22 (2H, m). ESI-TOF-MS m/z [M + H]+ calcd for C_{43}H_{51}N_{8}O_{7} 775.39; Found 775.38.

Synthesis of 27

To an ice-cooled solution of 18 (200 mg, 0.28 mmol) in dry DMF (3.0 mL) was added WSCI•HCl (83 mg, 0.43 mmol), HOBt•H_{2}O (64 mg, 0.43 mmol), DIEA (148 µL, 0.85 mmol) and 11-azido-3,6,9-trioxaundecan-1-amine (56 µL, 0.28 mmol). The solution was stirred overnight at rt. After dilution with AcOEt, the solution was washed with saturated NaHCO_{3} and brine followed by drying over Na_{2}SO_{4}. After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO_{2} (CHCl_{3} : MeOH : NH_{3} = 400 : 10 : 1 → 300 : 10 : 1) to give 27 (211 mg, 82%) as a colorless oil.

^1H-NMR (400 MHz, CDCl_{3}): δ 10.97 (1H, br), 8.53 (4H, d, J = 3.6 Hz), 7.60 (4H, t, J = 7.6 Hz), 7.45 (4H, d, J = 8.0 Hz), 7.12 (4H, t, J = 7.6 Hz), 7.05 (2H, s), 6.90 (1H, br), 4.33 (1H, m), 3.85 (8H, s), 3.75 (4H, dd, J = 19.2 Hz, 14 Hz), 3.66-3.24 (19H, m), 3.00-2.86 (2H, m), 1.35 (9H, s). ESI-TOF-MS m/z [M + H]+ calcd for C_{48}H_{62}N_{11}O_{7} 904.48; Found 904.50.

Synthesis of 28

To an ice-cooled solution of 27 (210 mg, 232 µmol) in CH_{2}Cl_{2} (1.5 mL) was added dropwise TFA (1.5 mL) and the solution was stirred for 1 h at rt. After removal of the solvent in vacuo, the residue was dissolved in H_{2}O. The mixture was neutralized with aq. NH_{3} on ice-cooling, diluted with saturated NaHCO_{3}, and then extracted with CH_{2}Cl_{2} (x2). The organic layer was dried over Na_{2}SO_{4}. The solution was concentrated by evaporation to give 28 (176 mg, 96%) as a pale yellow oil.

^1H-NMR (400 MHz, CDCl_{3}): δ 10.99 (1H, br), 8.51 (4H, d, J = 4.8 Hz), 7.63-7.59 (4H, m), 7.47 (4H, d, J = 8.0 Hz), 7.11 (4H, t, J = 6.4 Hz), 7.05 (2H, s), 3.86 (8H, s), 3.80 (4H, s), 3.69-3.34 (16H, m), 3.18-3.14 (2H, m), 2.58-2.51 (1H, m). ESI-TOF-MS m/z [M + H]+ calcd for C_{43}H_{54}N_{13}O_{5} 804.43; Found 804.44.
Synthesis of 29

To a solution of 28 (99 mg, 132 µmol) in dry DMF (2 mL) was added WSCI•HCl (36 mg, 185 µmol), HOBt•H₂O (28 mg, 185 µmol), DIEA (86 µL, 492 µmol) and 26 (115 mg, 148 µmol). The solution was stirred overnight at rt. After dilution with AcOEt, the solution was washed with saturated NaHCO₃ and brine followed by drying over Na₂SO₄. After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO₂ (CHCl₃ : MeOH : NH₃ = 200 : 10 : 1) to give 29 (140 mg, 73%) as a colorless amorphous powder.

¹H-NMR (400 MHz, CDCl₃) : δ 10.99 (2H, br), 8.54-8.51 (8H, m), 7.61-7.58 (8H, m), 7.52-7.43 (8H, m), 7.14-7.02 (12H, m), 5.44 (1H, m), 4.62-4.60 (1H, m), 4.29 (1H, m), 3.84-3.18 (42H, m).
2.95-2.85 (6H, m), 2.27-2.17 (2H, m), 1.27 (9H, s). ESI-TOF-MS 1561.78 [M + H]+. ESI-TOF-MS m/z [M + H]+ calcd for C₈₆H₁₀₂N₁₉O₁₀ 1561.88; Found 1561.78.

Synthesis of 30

To an ice-cooled solution of 29 (139 mg, 89 µmol) in CH₂Cl₂ (2 mL) was added dropwise TFA (2 mL) and the solution was stirred for 2 h at rt. After removal of the solvent in vacuo, the residue was dissolved in H₂O. The mixture was neutralized with aq. NH₃ on ice-cooling, diluted with saturated NaHCO₃, and then extracted with CH₂Cl₂. The organic layer was dried over Na₂SO₄. The solution was concentrated by evaporation to give 30 (130 mg, quant) as a pale red amorphous powder.

¹H-NMR (400 MHz, CDCl₃): δ 10.99 (2H, br), 8.50 (8H, dd, J = 7.6 Hz, 4.0 Hz), 7.62-7.57 (8H, m), 7.48-7.43 (8H, t, J = 8.8 Hz), 7.14-7.02 (12H, m), 4.66 (1H, m), 3.84-3.06 (46H, m), 2.96-2.86 (2H, m), 2.31 (2H, m). ESI-TOF-MS m/z [M + H]+ calcd for C₈₁H₉₄N₁₉O₈ 1460.75; Found 1460.76.

Synthesis of 31

To an ice-cooled solution of 30 (40 mg, 27 µmol) in dry DMF (1.5 mL) was added WSCI•HCl (6.4 mg, 33 µmol), HOBt•H₂O (5 mg, 25 µmol), DIEA (22 µL, 132 µmol) and Boc-L-Pro (7 mg, 33 µmol). The solution was stirred for 4.5 h at rt. After dilution with AcOEt, the solution was washed with saturated NaHCO₃ and brine followed by drying over Na₂SO₄. After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO₂ (CHCl₃ : MeOH : NH₃ = 400 : 4 : 1 → 160 : 20 : 1) to give 31 (34 mg, 75%) as a pale yellow oil.

¹H-NMR (400 MHz, CDCl₃): δ 10.95-10.94 (2H, m), 8.52 (8H, t, J = 4.0 Hz), 7.58 (8H, t, J = 7.6 Hz), 7.44 (8H, t, J = 6.8 Hz), 7.32 (1H, m), 7.13-7.11 (8H, t, J = 5.2 Hz), 7.02-7.00 (3H, m), 6.72 (1H, m), 4.60-4.52 (2H, m), 4.11 (1H, m), 3.83 (16H, s), 3.71-3.18 (28H, m), 2.90-2.89 (3H, m), 2.25 (1H, m), 1.93 (2H, m), 1.71 (13H, m). ESI-TOF-MS m/z [M + H]+ calcd for C₉₁H₁₀₉N₂₀O₁₁ 1658.86; Found 1658.89.

Synthesis of 32

To an ice-cooled solution of 31 (32 mg, 19 µmol) in dry CH₂Cl₂ (1.0 mL) was added dropwise TFA (1.0 mL) and the solution was stirred for 1 h at rt. After removal of the solvent in vacuo, the residue was dissolved in H₂O. The mixture was neutralized with aq. NH₃ on ice-cooling, diluted with saturated NaHCO₃, and then extracted with CH₂Cl₂ (x2). The organic layer was washed with
brine and dried over Na₂SO₄. The solution was concentrated by evaporation to give 32 (32 mg, quant) as a colorless oil.

1H-NMR (400 MHz, CDCl₃) : δ 10.95 (2H, brs), 8.51 (8H, t, J = 5.2 Hz), 8.04 (1H, m), 7.58 (8H, t, J = 8.0 Hz), 7.43 (8H, t, J = 8.4 Hz), 7.14-7.10 (8H, m), 7.04 (4H, s), 4.57-4.47 (2H, m), 3.83 (16H, s), 3.80-2.52 (31H, m), 2.27-1.66(7H, m). ESI-TOF-MS m/z [M + H]⁺ calcd for C₈₆H₁₀₁N₂₀Oₙ 1558.81; Found 1558.84.

Synthesis of 33

To an ice-cooled solution of 4-(dimethylamino)-2-butenoic acid hydrochloride (7.0 mg, 43 μmol) in dry DMF (1 mL) was added DIEA (19 µL, 116 μmol), Py-BOP (22 mg, 43 μmol) and 32 (30 mg, 19 μmol). The solution was stirred overnight at rt. After dilution with water, the solution was washed with saturated NaHCO₃ and brine followed by drying over Na₂SO₄. After removal of the solvent by evaporation, the residue was purified by column chromatography on SiO₂ (CHCl₃ : MeOH : NH₃ = 400 : 4 : 1→160 : 20 : 1) to give 33 (19 mg, 60%) as a colorless oil.

1H-NMR (400 MHz, CDCl₃) : δ 10.95 (2H, br), 8.50 (8H, dd, J = 11.2 Hz, 4.4 Hz), 7.58 (8H, t, J = 7.6 Hz), 7.43 (8H, t, J = 8.4 Hz), 7.34-7.32 (2H, m), 7.13-7.09 (8H, m), 7.01 (4H, d, J = 5.2 Hz), 6.80-6.74 (1H, m), 4.60-4.58 (1H, m), 4.38 (2H, m), 3.83 (16H, s), 3.79-3.01 (28H, m), 2.88-2.84 (2H, m), 2.39-2.35 (1H, m), 2.21 (8H, br), 1.75 (4H, m). ESI-TOF-MS m/z [M + H]⁺ calcd for C₉₂H₁₁₀N₂₁O₁₀ 1669.88; Found 1669.91.

Synthesis of 14

A solution of 33 (18 mg, 11μmol) and Pd/C-ethylenediamine complex (10 mg) in MeOH-CH₂Cl₂ (1 : 1, 5 mL) was vigorously stirred for 5 h under H₂ atmosphere at rt. After filtration, the solvent was removed by evaporation to give the crude 14 (20 mg) as a pale yellow oil. This material used for the next reaction without further purification.

ESI-TOF-MS m/z [M + H]⁺ calcd for C₉₂H₁₁₂N₁₀O₁₀ 1642.88; Found 1642.91.

Synthesis of 10

A mixture of crude 14 (10 mg), DIEA (18 µL, 108 μmol), Oregon Green 488-SE (2.5 mg, 5 μmol) in dry DMF (2 mL) was stirred for 3 h at rt. The reaction was monitored by reverse-phase HPLC. Purification by reverse-phase HPLC and subsequent lyophilization gave 10 (2.4 mg, 11%
in two steps) as a yellow powder. The purity of 10 was determined to be > 95% by HPLC analysis (UV, \( \lambda = 220 \text{ nm} \)).

HPLC conditions: column; YMC-pack ODS-A, 250 x 20 mm, mobile phase; CH$_3$CN (containing 0.1% TFA) / H$_2$O (containing 0.1% TFA) = 5 / 95 (10 min) → 50 / 50 (linear gradient over 50 min), flow rate; 9.9 mL/min, detection; UV (\( \lambda = 220 \text{ nm} \)).

ESI-TOF-MS m/z \([M + H]^+\) calcd for C$_{113}$H$_{120}$F$_2$N$_{19}$O$_{16}$ 2037.92; Found 2037.91.

Synthesis of 34

To a solution of 30 (20 mg, 14 \( \mu \text{mol} \)) in dry DMF (1.0 mL) was added DIEA (7 \( \mu \text{L}, 41 \mu \text{mol} \)) and chloroacetic acid N-hydroxysuccinimidy l ester (4.0 mg, 19 \( \mu \text{mol} \)) and the solution was stirred for 2 h at rt. After dilution with AcOEt, the solution was washed with saturated NaHCO$_3$ and brine followed by drying over Na$_2$SO$_4$. The solvent was removed by evaporation to give crude 34 (21 mg) as a pale yellow oil. This material used for the next reaction without further purification.

ESI-TOF-MS m/z \([M + H]^+\) calcd for C$_{83}$H$_{95}$ClN$_{19}$O$_9$ 1536.72; Found 1536.72.
Synthesis of 35

A solution of the crude 34 (21 mg) and Pd/C-ethylenediamine complex (10 mg) in MeOH-CH₂Cl₂ (1 : 1, 5 mL) was vigorously stirred for 5 h under H₂ atmosphere at rt. After filtration, the solvent was removed by evaporation to give crude 35 (17 mg) as a pale yellow oil. This material used for the next reaction without further purification.

ESI-TOF-MS m/z [M + H]⁺ calcd for C₈₃H₇₇ClN₁₇O₉ 1510.73; Found 1510.74.

Synthesis of 11

A mixture of the crude 35 (17 mg), DIEA (18 µL, 108 µmol), Oregon Green 488-SE (2.5 mg, 5 µmol) in dry DMF (1.5 mL) was stirred for 3 h at rt. The reaction was monitored by reverse-phase HPLC. Purification by reverse-phase HPLC and lyophilization gave 11 (3.3 mg, 13% in three steps) as a yellow powder. The purity of 11 was determined to be > 95% by HPLC analysis (UV, λ = 220 nm).

HPLC conditions: column; YMC-pack ODS-A, 250 x 20 mm, mobile phase; CH₃CN (containing 0.1% TFA) / H₂O (containing 0.1% TFA) = 0 / 100 → 50 / 50 (linear gradient over 50 min), flow rate; 9.9 mL/min, detection; UV (λ = 220 nm).

ESI-TOF-MS m/z [M + H]⁺ calcd for C₁₀₄H₁₀₅ClF₂N₁₇O₁₉ 1905.77; Found 1905.76.

Synthesis of 12

A mixture of crude 14 (7.1 mg), DIEA (10 µL, 58 µmol), biotin-SE (9.0 mg, 26 µmol) in dry DMF (1 mL) was stirred for 13 h at rt. The reaction was monitored by reverse-phase HPLC. Purification by reverse-phase HPLC and lyophilization gave 12 (2.0 mg, 15% in two steps) as a colorless powder. The purity of 12 was determined to be > 95% by HPLC analysis (UV, λ = 220 nm).
HPLC conditions: column; YMC-pack ODS-A, 250 x 10 mm, mobile phase; CH$_3$CN (containing 0.1% TFA) / H$_2$O (containing 0.1% TFA) = 5 / 95 (10 min) → 45 / 55 (linear gradient over 40 min), flow rate; 3.0 mL/min, detection; UV ($\lambda = 220$ nm).

ESI-TOF-MS $m/z$ [M + H]$^+$ calcd for C$_{102}$H$_{126}$N$_{21}$O$_{12}$S 623.32; Found 624.33.

**Synthesis of 13-4Zn(II)**

Mono-Sulfo-NHS-Nanogold (purchased from Nanoprobes) (6 nmol) was dissolved in MilliQ water (200 μL) and mixed with the solution (200 μL) of the zinc complex 14-4Zn(II) (~ 120 mmol) in 50 mM HEPES (pH 8.0), in which concentration of 14-4Zn(II) was determined by UV absorbance at 280 nm using the measured extinction coefficient ($\varepsilon_{280 \text{nm}} = 5170 \text{ cm}^{-1}\text{M}^{-1}$). The mixture was incubated at rt for 3 h with gentle shaking. The mixture was transferred into a dialysis membrane (MWCO: 14,000) and dialyzed (1 h x 3) against 300 mL of 50 mM HEPES (pH 7.2) containing 50 μM ZnCl$_2$ at rt to remove the excess of 14-4Zn(II). The conjugation of 14-4Zn(II) with the nanogold was confirmed by UV absorbance measurement at 280 nm and 420 nm, in which the absorbance ratio ($A_{280 \text{nm}} / A_{420 \text{nm}} = 2.77$) of the nanogold and the extinction coefficient of 14-4Zn(II) were used to estimate the labeling yield.
