**Source of Data**

Using the University of Florida Health (UFH) Integrated Data Repository as Honest Broker for data de-identification we have created a single-center perioperative longitudinal cohort that integrated electronic health record (EHR) data with administrative datasets as previously described. Using residency zip code, we linked the cohort with the United States Census data to calculate residing neighborhood characteristics and distance from hospital. We included all inpatient operative procedures performed between June 1, 2014 and September 20, 2020. The date of death was determined using hospital records and the search of the Social Security Death Index.

**Participants**

We included all patients with age greater or equal to 18 years admitted between June 1, 2014 and September 20, 2020 with the admission involving any type of inpatient operative procedure. Detailed exclusion criteria are shown in [eFigure 1](#). When a patient had multiple surgeries during one admission, only the first surgery was used in the analysis. The final retrospective cohort consisted of 41,812 patients undergoing 52,117 surgeries; the prospective cohort consisted of 19,132 patients undergoing 22,300 surgeries.

**Outcomes**

We have developed and implemented an array of AI algorithms for perioperative real-time data integration, harmonization and preprocessing, computable phenotyping and dynamic perioperative risk assessment for eight postoperative complications including prolonged (>48 hours) intensive care unit (ICU) stay and mechanical ventilation (MV), neurological complications including delirium, cardiovascular complications, acute kidney injury (AKI), venous thromboembolism (VTE), sepsis, and wound complications that include infectious and mechanical wound complications. We used the exact dates to calculate the duration of MV and ICU stay. We defined AKI using KDIGO consensus criteria while a set of previously described criteria was applied to annotate the remaining complications. The algorithm also calculates risk probabilities for death at 30 days and 90 days 1, 3, 6, 12 and 24 months after index surgery.

We report six MySurgeryRisk model versions, including three generalized additive models and three random forest models using 55, 101 and 135 input features ([eTable 11](#)). These models followed the same rules for data preprocessing, feature selection, and model development methods as previously described.

**Predictor Variables**

From 285 available preoperative demographic, socio-economic, administrative, clinical, pharmacy and laboratory variables we have derived the set of preoperative predictor features. For each patient we considered all potential preoperative predictors available in the harmonized dataset. Patient comorbidities were derived using up to 50 preoperative The International Classification of Diseases (ICD), Ninth Revision, Clinical Modification (ICD-9-CM) and the International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM) codes. We used validated methods to define binary preoperative comorbidity variables and composite Charlson comorbidity index. We extracted medications dispensed in the one year prior to surgery day using RxNorms data grouped into drug classes according to the United States Department of Veterans Affairs National Drug File-Reference Terminology; medications were derived from RxNorm codes grouped into drug classes as previously described. We modeled primary procedure type on Current Procedural Terminology (CPT) with a forest structure in which nodes represented groups of procedures, roots presented the most general groups of procedures, and leaf nodes represented specific procedures.
Supervised feature selection was performed using the variance inflation factors to evaluate collinearity and remove highly collinear predictors (VIF package in R \(^{10}\)). Due to the nature of clinical data many predictors are derived from a single attribute thus the likelihood of collinearity among variables is high.

### Data Transformer

*MySurgeryRisk* transforms data from any native EHR format to the processed dataset optimized for use in predictive models. New complex variables are created (as described above in “Predictor Variables”) and are used in data preprocessing, feature transformation and feature selection.

Data preprocessing included data cleaning, outlier removal and missing data imputation. \(^{15,16}\) For initial data cleaning we tagged the inconclusive test results as missing. Set of automatic rules was used for the removal of outliers that were considered unreasonable observations by medical experts. For continuous variables, observations that fell in the top and bottom 1% of the distribution were considered as outliers, and they were imputed with a random number generated from the range between 0.5th and 5th percentiles and between 95th and 99.5th percentiles, respectively. All missing observations were imputed using automated algorithm. For nominal variables with missing entries, a distinct “missing” category was created. For continuous variables, the mean value for a given variable was used for imputation.

Feature transformation was applied to reduce dimensionality of the data and decrease the chance of overfitting. We optimized categorical and nominal variables with multiple levels (such as zip code or surgeon’s ID) using conditional probabilities for a patient to have a particular variable value conditioning on each outcome separately \(^{17}\). We substituted the values \(x_i\) of categorical variables with the ratios

\[
\log[P(X_i = x_i \mid C = 1) / P(X_i = x_i \mid C = 0)]
\]

where

\[
P(X_i = x \mid C = c) = \#\{j : C^j = c, x^j = x\}/\#\{j : C^j = c\}
\]

and then treated each categorical variable as an ordered variable. In case of classification trees such substitution gives the optimal splits, in terms of cross-entropy or Gini index. Based on our experiments, such modeling of categorical variables provides less overfitting than when using binary dummy variables (data not shown).

In order to obtain a reliable estimate of \(P(X_i = x \mid C = c)\), categorical risk factors with categories with fewer than 100 records were grouped together and labeled "other". This "other" group was further split into several subgroups where each subgroup contained categories with similar proportions of patients from different classes. This was achieved by performing k-means clustering\(^{15}\) on the set of categories in the "other" group. We set the number of clusters to 2 if there were at least 3 categories in the "other" group; otherwise we set it to 1 (no clustering). The computations were implemented in python software using the kmeans function from scipy package. The rational for this approach was to reduce the over-fitting of the data, since large clusters are less affected by random data splits, than small individual categories. Computational results showed that indeed this technique improved the stability of the model and reduced the effects of over-fitting.

Surgical procedure codes were optimized using forest of trees approach to group Current Procedural Terminology (CPT) codes \(^{17}\) followed by a conditional probability calculation approach described above. Each node represents a group of procedures, with roots representing most general groups of procedures and leaf nodes representing specific procedures.

### Optimization of Surgical Procedure Codes

The types of surgical procedures were determined using the primary CPT processing codes. The existing ~ 9000 codes are prefix-based on anatomical location of surgery and often lack detailed descriptions of surgical approach. Although they are important features for risk stratification, their high dimensionality renders them challenging for the use in predictive models. In addition, while for some procedure codes only a few patients were encountered in the cohort, the estimation of probabilities by counting the number of such patients in each class would be unreliable.

To overcome this issue we combined procedures with small number of patients into groups of procedures based on their similarity according to the CPT classification using forest of trees approach as previously described \(^{17}\) and then optimized the CPT codes using condition probability described above. We created a hierarchical tree of CPT, which is structured by levels. Level 0 (root) represents all CPT codes; level 1 contains Clinical Classifications Software...
(CCS) codes; level 2 contains ranges of CPT codes and level 3 contains specific CPT codes. For example, “ALL”, “CCS 1”, “61000-61050” and “61000” is an example of the path from root to the leaf node. We added a node of ‘Missing’ to level 1 of this tree. For each CPT code without matched CCS code, we generated a branch of ‘Missing’ node at level 1 with the CPT code itself as the nodes at level 2 as well as level 3. For each leaf node, we assigned a number of patients who had a type of surgical procedure described by this node’s code, and for each non-leaf node (such nodes represent general classes of procedures) we assigned a number of patients whose type of surgical procedure belongs to this class. Procedures were aggregated up to the top level of the CPT hierarchy such that each procedure/group of procedures contained at least 100 patients. The value of this parameter was selected based on a grid search through the values 50, 100, 150, 250 and 500. To assign continuous values to CPT codes, we located the leaf nodes containing CPT codes and find the continuous value using the log of conditional odds of positive outcome described above.

**Calculation of Risk Score**

A set of algorithms was trained to calculate patient-level risk probabilities for each of eight complications. The calculated risk probabilities were subsequently used as input data for the algorithm trained to calculate mortality risk scores. The final output produces *MySurgeryRisk*, a personalized risk panel for eight major complications and mortality risk at 30 and 90 days after surgery together with a list of the top three features contributing to each of the calculated risk scores.

**Patient-Level Risk Scores**, representing the probability of each complication during hospitalization after index surgery, were calculated. For each complication separately, we used risk probabilities calculated by the algorithm to define the optimal cutoff values that best categorize patients into low and high risk categories by maximizing the Youden index. The most important features contributing to the risk for an individual patient were derived based on how different she or he is from the patient with an “average” risk. Features that contribute the most to a high or low risk score for a particular complication in a specific patient were determined by creating an average patient for each complication. For categorical features, numerical values were assigned to each class and then features for average patient were set to an actually observed value, closest to the median value among all patients of each feature. Next, each feature of the average patient was replaced with the value of that feature from a certain patient and the change in the risk score was calculated. This procedure was repeated for all features one at a time and features with the highest positive and negative change were determined as the features contributing the most to a high and low risk score, respectively.

**Patient-Level Mortality Scores**, representing the probability of death at 30 and 90 days after index surgery, were calculated using a random forests classifier trained over the individual complication risk probabilities within a 5-fold cross validation design. We automatically tuned the parameters for each classifier through maximizing accuracy as the cross validation performance score over searching a parameter space.

**Model Performance**

We assessed each model’s discrimination using the AUROC and model accuracy by determining the fraction of correct classification for each model. Using the optimal thresholds for risk probabilities we built the classification table from which we calculated sensitivity, specificity, and positive and negative predictive values for each model. Relative risk was calculated as the ratio of the absolute risk of the complication for high and low risk groups for each complication. We used bootstrap sampling and nonparametric methods to obtain 95% confidence intervals for all performance measures.

**Generalized Additive Model**

We estimated the probability of outcome \((C = 1, \text{otherwise } C = 0)\) by using a generalized additive model:

\[
\logit P(C = 1|X = x) = \alpha + \sum_{i=1}^{m} f_i(x_i)
\]

where \(m\) is the number of risk factors, \(X = (X_1, ..., X_m)\) are the risk factors, \(x = (x_1, ..., x_m)\) are the values of these factors, \(f_i\) is a nonlinear risk function associated with the \(i\)th risk factor and \(\alpha\) is a free term. Nonlinear risk functions \(f_i\) were estimated for each feature with cubic splines via a local scoring algorithm. The degrees of freedom for
each spline were estimated by maximizing restricted likelihood function \( 23 \). Degrees of freedom characterize a curvature of a spline, with value 1 corresponding to a linear function. Risk predictors with estimated degrees of freedom close to 1 were not smoothed in the final model; instead the original values of risk predictors \( x_i \) were used. Therefore, the final model has the following form as in equation (2) where \( I \) is a set of risk predictors with estimated degrees of freedom close to 1 and \( w_i \) is the linear weight of the \( i \)th risk predictors.

\[
\text{logit } P(E = 1|X = x) = \alpha + \sum_{i \in I} w_i \cdot x_i + \sum_{i \in I} f_i(x_i)
\] (2)

**Random Forests Classifier**

Random forests (RF) is a machine learning method which generates and uses a collection of numerous classification and regression trees (CART) and aggregates their results \( 24 \). Each of the generated classifiers are trained on a bootstrap sample of the training data. Each generated tree in the random forests predicts the outcome and then the model generates the final outcome through aggregating the outcomes of all trees using majority voting of the trees. Random forests employ bootstrap aggregation \( 25 \) and random feature selection \( 26 \) to construct a set of decision trees, thus, applying controlled variation. \( 27 \) We used the R implementation of the random forests classifier. \( 28 \) We used the mean decrease in accuracy measure to determine feature importance. In this approach, a feature is determined to be more important if removing it from the random forests causes a greater decrease in accuracy.

**The Real-Time Intelligent Perioperative Platform**

**Web Application Design**

The previously reported MySurgeryRisk output platform was a secure web interface. \( 8 \) The web application is based on Tomcat and Java Jersey EE frameworks. The front-end interfaces are written with PHP, HTML, and relative languages; the back-end follows RESTful APIs. The MySurgeryRisk web portal uses a Shibboleth identification service for authorization and is confined to the University of Florida Health secure network, which is accessible offsite through a virtual private network. The web portal provides surgeons with their patients’ demographic information, planned surgery, risk factors, and predicted probabilities for postoperative complications and mortality (eFigures 2-6). Surgeons can record their own predictions for complications and mortality before and after viewing model predictions.

**Mobile Device Application Design**

The MySurgeryRisk mobile application performs all the same functions as the website, with the convenience of being accessible on mobile devices. In addition, the mobile application identifies similar patients from the retrospective database, and provides surgeons with risk profiles for those patients. Similar patients are identified using primary surgeon performing the operation, primary procedure code, patient demographics, and patient Charleston Comorbidity Index. The application has two modes: 1) data collection mode, in which surgeons make their own risk assessments before and after viewing model risk assessments, and 2) view only mode, in which surgeons view model predictions without submitting their own risk assessments.

The application is built using the dart programming language and Flutter framework. It run on iOS, android, and macOS with plans to expand to run on Windows operating systems and the Web. The application has been designed and built with speed and security in mind. All data is received and transmitted with secure socket layer (SSL) encryption. The mobile application uses a Shibboleth identification service for authorization and is confined to the University of Florida Health secure network, accessible offsite through a virtual private network. Users can also choose to configure a pin code or biometric security (fingerprint or face scan) for efficient login access. The mobile application loads data approximately ten times faster than the web portal. Application screenshots are provided in eFigure 2 and eFigures 8-11. The output displays a list of operating room cases, information regarding each individual patient, each patient’s risk for eight postoperative complications plus 30-day and 90-day mortality, the top three features conferring risk for those complications, and complication trends for individual surgeons compared with their colleagues over time.

**Analytic Workflow of MySurgeryRisk**
MySurgeryRisk is an automated EHR algorithm that will be implemented in real-time using the intelligent perioperative platform developed by our group. This platform resides in a secure environment and in real time integrates and transforms EHR data, runs predictive algorithms, produces outputs for physicians, inputs their feedback and prospectively collects data for the future retraining of the prediction models.

The MySurgeryRisk platform consists of three main components, including Permanent Data Store, FHIR Adapter, and Intelligent Engine, as previously described. The Permanent Data Store directly stores the data from hospital data warehouse and other sources through FHIR adapter then applying standard data model OMOP to formulate the uniformed clinical database for analysis. The FHIR adapter works as the hub of data exchanging which provides Restful API and format transforming services. It not only serves as the messaging protocol for other components of the platform but also expose the data services for applications with the widely accepted interpretable specification. The Intelligent Engine receives the transformed data through FHIR adapter and performs computational algorithms to compute patient-level risk scores for complications and mortality. It provides containerized development environments for researchers to develop their models and pipelines and easy final deployment in a real-time productional setting. The MySurgeryRisk platform architecture is illustrated in eFigure 2. We use the NoSQL database Cassandra to store large volumes of intermediate and output data for streaming services. Finally, for the Application platform, we developed a web portal and mobile device application to provide real-time displays of risk scores, as described in detail below. To comply with the Health Insurance Portability and Accountability Act, authorized surgeons can only access the web portal and mobile application within the UF Health virtual private network, which requires multiple layers of authorization to maintain system security. All predictions are saved in the Cassandra database for future comparative studies.
eFigure 1. Flow Diagram of MySurgeryRisk Model Development and Validation Cohorts

IDEALIST DATA
06/01/2014 - 09/20/2020
108,767 unique patients
212,483 unique encounters
with surgical information

Exclude encounters that don't meet initial search criteria:
1. Patient age is below 18 on admission: 15
2. Not UH patient: 1,891
3. Not Hospital Encounter: 1

Exclude encounters that are not inpatient encounter:
1. Outpatient and recurrent outpatient: 2,218
2. Ambulatory surgery patient: 63,079

Exclude for missing information:
1. Missing admission or discharge date: 0

Exclude incomplete and minor surgeries:
1. Surgery scheduled site not in main OR site: 167
2. Organ donation surgery: 673
3. Anesthesia given outside OR: 7,146
4. Gastrointestinal related small procedure: 0
5. Minor procedures done for the purpose of control pain: 70
6. Surgery stop date/time missing: 0
7. Not first surgery: 1,573

Development Cohort
06/01/2014 - 11/27/2018
52,117 encounters
41,812 patients

Validation Cohort
11/28/2018 - 09/20/2020
22,300 encounters
19,132 patients

Exclude encounters that don’t meet initial search criteria:
1. Patient age is below 18 on admission: 4
2. Not UH patient: 308
3. Not Hospital Encounter: 0

Exclude encounters that are not inpatient encounter:
1. Outpatient and recurrent outpatient: 1,352
2. Ambulatory surgery patient: 26,925

Exclude for missing information:
1. Missing admission or discharge date: 24

Exclude incomplete and minor surgeries:
1. Surgery scheduled site not in main OR site: 60
2. Organ donation surgery: 42
3. Anesthesia given outside OR: 1,740
4. Gastrointestinal related small procedure: 9
5. Minor procedures done for the purpose of control pain: 51
6. Surgery stop date/time missing: 0
7. Not first surgery: 924
The Integrated Data Repository (IDR) supplies raw data, which is supplied to the intelligent engine using the Kafka messaging protocol. All Analytics Engine components are deployed as Docker containers to isolate each component so that the system does not need to be reconfigured with each deployment in a new data environment. The NoSQL database Cassandra is used to store large volumes of intermediate and output data for streaming services, deploying the web portal and mobile device applications via a web server.

|------------------------------------------------------------------------|---------------------------------------|
| Variance of Glucose in blood, mg/dL                                    | 55 (type)                             |
| Count of Glucose in blood test                                         | 55 (type)                             |
| Min of Serum CO2, mmol/L                                               | 55 (type)                             |
| Max of Serum CO2, mmol/L                                               | 55 (type)                             |
| Average of Serum CO2, mmol/L                                           | 55 (type)                             |
| Variance of Serum CO2, mmol/L                                          | 55 (type)                             |
| Count of Serum CO2 test                                                | 55 (type)                             |
| Min of Urea nitrogen in blood, mg/dL                                   | 55 (type)                             |
| Max of Urea nitrogen in blood, mg/dL                                   | 55 (type)                             |
| Average of Urea nitrogen in blood, mg/dL                               | 55 (type)                             |
| Variance of Urea nitrogen in blood, mg/dL                              | 55 (type)                             |
| Count of Urea nitrogen in blood test                                  | 55 (type)                             |
| Min of Urea Nitrogen-Creatinine ratio                                  | 55 (type)                             |
| Max of Urea Nitrogen-Creatinine ratio                                  | 55 (type)                             |
| Average of Urea Nitrogen-Creatinine ratio                              | 55 (type)                             |
| Variance of Urea Nitrogen-Creatinine ratio                            | 55 (type)                             |
| Count of Urea Nitrogen-Creatinine ratio                                | 55 (type)                             |
| Min of Serum Sodium, mmol/L                                            | 55 (type)                             |
| Max of Serum Sodium, mmol/L                                            | 55 (type)                             |
| Variance of Serum Sodium, mmol/L                                      | 55 (type)                             |
| Average of Serum Sodium, mmol/L                                       | 55 (type)                             |
| Count of Serum Sodium test                                             | 55 (type)                             |
| Average of Potassium in serum, mmol/L                                  | 55 (type)                             |
| Count of Potassium in serum test                                      | 55 (type)                             |
| Max of Red cell distribution width in Blood, %                         | 55 (type)                             |
| Min of Red cell distribution width in Blood, %                         | 55 (type)                             |
| Feature                                               | 55 | 101 | 135 | 55 (type) | 101 (type) | 135 (type) |
|-------------------------------------------------------|----|-----|-----|-----------|------------|------------|
| Average of Red cell distribution width in Blood, %    | X  | X   |     |           |            |            |
| Variance of Red cell distribution width in Blood, %   |    | X   |     |           |            |            |
| Min of platelet in blood, thou/uL                     |    | X   |     |           |            |            |
| Max of platelet in blood, thou/uL                      | X  | X   |     |           |            |            |
| Average of platelet in blood, thou/uL                  | X  | X   |     |           |            |            |
| Variance of platelet in blood, thou/uL                | X  | X   |     |           |            |            |
| Min of Serum creatinine, mg/dL                         |    | X   |     |           |            |            |
| Max of Serum creatinine, mg/dL                         |    | X   |     |           |            |            |
| Average of Serum creatinine, mg/dL                     |    | X   |     |           |            |            |
| Variance of Serum creatinine, mg/dL                    | X  |     |     |           |            |            |
| Count of Serum creatinine test                         |    | X   |     |           |            |            |
| Max of chloride in Serum, mmol/L                       |    | X   |     |           |            |            |
| Average of chloride in Serum, mmol/L                   |    | X   |     |           |            |            |
| Variance of chloride in Serum, mmol/L                  | X  |     |     |           |            |            |
| Count of chloride in Serum test                        | X  |     |     |           |            |            |

'X' marks use of the feature.
Abbreviations: ACE, Angiotensin-converting enzyme; CKD, chronic kidney disease.
**eTable 2. Development and Validation Cohort Characteristics of Features Used for MySurgeryRisk Model Development**

| Features                                        | Development Cohort | Validation Cohort |
|------------------------------------------------|--------------------|-------------------|
| **Number of patients, n**                      | 41,812             | 19,132            |
| **Demographic information**                    |                    |                   |
| Age, years, mean (SD)<sup>a</sup>              | 56 (18)            | 58 (17)           |
| Sex, n (%)                                      |                    |                   |
| Male                                           | 20,830 (49.8)      | 9,672 (50.6)      |
| Female                                         | 20,982 (50.2)      | 9,460 (49.4)      |
| Race, n (%)<sup>b</sup>                        |                    |                   |
| African American                               | 6,225 (14.9)       | 2,765 (14.5)      |
| White                                          | 32,286 (77.2)      | 14,777 (77.2)     |
| Other<sup>c</sup>                              | 2,667 (6.4)        | 1,235 (6.5)       |
| Missing                                        | 634 (1.5)          | 355 (1.9)         |
| Ethnicity, n (%)<sup>b</sup>                   |                    |                   |
| Non-Hispanic                                   | 39,067 (93.4)      | 17,663 (92.3)     |

Abbreviations: SD, standard deviation; IQR, interquartile range; OB, obstetrician; ACE, Angiotensin-converting enzyme.

*Data is reported based on values calculated at the latest hospital admission.

*Race and ethnicity are self-reported.

*Other race includes American Indian/Alaskan Native, Asian, Native Hawaiian/other Pacific Islander, and multiracial.

*Other surgery type includes plastic surgery, burn surgery, pediatric surgery, transplantation, ophthalmology, medicine gastroenterology, and interventional cardiology.
**eTable 3.** Generalized Additive Model Performance Measurements for Complications With 95% CIs Calculated by 1000 Bootstrap Samples on the Validation Cohort

| Complication                              | Input features (n) | Sensitivity | Specificity | PPV     | NPV     | Accuracy | AUROC  | AUPRC  | Thresh old |
|-------------------------------------------|--------------------|-------------|-------------|---------|---------|----------|--------|--------|------------|
| Cardiovascular complication               | 55                 | 0.7 (0.69, 0.71) | 0.75 (0.73, 0.76) | 0.33 (0.32, 0.34) | 0.93 (0.93, 0.94) | 0.71 (0.7, 0.71) | 0.8 (0.79, 0.8) | 0.45 (0.43, 0.46) | 0.13       |
|                                           | 101                | 0.67 (0.66, 0.68) | 0.75 (0.74, 0.76) | 0.31 (0.3, 0.32) | 0.93 (0.93, 0.94) | 0.68 (0.68, 0.69) | 0.78 (0.77, 0.79) | 0.44 (0.42, 0.46) | 0.11       |
|                                           | 135                | 0.71 (0.71, 0.72) | 0.75 (0.74, 0.77) | 0.34 (0.33, 0.35) | 0.94 (0.93, 0.94) | 0.72 (0.71, 0.72) | 0.81 (0.8, 0.82) | 0.48 (0.47, 0.5)  | 0.12       |
| Prolonged ICU stay                       | 55                 | 0.74 (0.73, 0.74) | 0.81 (0.8, 0.82) | 0.55 (0.54, 0.56) | 0.91 (0.9, 0.91) | 0.76 (0.75, 0.76) | 0.86 (0.86, 0.87) | 0.74 (0.72, 0.75) | 0.2        |
|                                           | 101                | 0.75 (0.75, 0.76) | 0.77 (0.76, 0.78) | 0.55 (0.54, 0.56) | 0.89 (0.89, 0.9)  | 0.76 (0.75, 0.76) | 0.85 (0.84, 0.86) | 0.71 (0.7, 0.73)  | 0.17       |
|                                           | 135                | 0.79 (0.79, 0.8) | 0.78 (0.77, 0.79) | 0.6 (0.59, 0.61) | 0.9 (0.89, 0.9)   | 0.79 (0.78, 0.79) | 0.88 (0.87, 0.88) | 0.77 (0.76, 0.78) | 0.19       |
| Neurological complication and delirium    | 55                 | 0.79 (0.78, 0.79) | 0.77 (0.75, 0.78) | 0.39 (0.38, 0.4)  | 0.95 (0.95, 0.95) | 0.78 (0.78, 0.79) | 0.85 (0.85, 0.86) | 0.57 (0.55, 0.59) | 0.12       |
|                                           | 101                | 0.72 (0.71, 0.72) | 0.78 (0.77, 0.8)  | 0.33 (0.32, 0.34) | 0.95 (0.95, 0.95) | 0.73 (0.72, 0.73) | 0.83 (0.82, 0.84) | 0.5 (0.48, 0.52)  | 0.1        |
|                                           | 135                | 0.77 (0.77, 0.78) | 0.79 (0.78, 0.8)  | 0.38 (0.37, 0.39) | 0.96 (0.95, 0.96) | 0.77 (0.77, 0.78) | 0.86 (0.86, 0.87) | 0.58 (0.57, 0.6)  | 0.1        |

Model version key: V1=previous GAM versions of MySurgeryRisk, V2=latest Random Forest versions of MySurgeryRisk, 55=55 input features, 101=101 input features, 135=135 input features.

Abbreviations: GAM, generalized additive model; RF, random forest; NRI, net reclassification improvement; ICU, intensive care unit; CI, confidence interval; AUROC, area under the receiver operating characteristic curve; NRI, Net Reclassification index.

NRI is reported as summation of NRIe (fraction of event reclassification) and NRIne (fraction of no event reclassification). Reclassifications are reported in percentage.

P values for AUROC comparison was performed using DeLong paired method.

For NRI, event reclassification, and no-event reclassification, t-test was performed to produce p-values.

95% Confidence intervals were produced using Bootstrap method for 1000 samples.

Model version key: V1=previous GAM versions of MySurgeryRisk, V2=latest Random Forest versions of MySurgeryRisk, .55=55 input features, .101=101 input features, .135=135 input features.

Abbreviations: GAM, generalized additive model; RF, random forest; ICU, intensive care unit.

Risk values are presented with 95% confidence intervals.
