Abstract

Existing video denoising methods typically assume noisy videos are degraded from clean videos by adding Gaussian noise. However, deep models trained on such a degradation assumption will inevitably give rise to poor performance for real videos due to degradation mismatch. Although some studies attempt to train deep models on noisy and noise-free video pairs captured by cameras, such models can only work well for specific cameras and do not generalize well for other videos. In this paper, we propose to lift this limitation and focus on the problem of general real video denoising with the aim to generalize well on unseen real-world videos. We tackle this problem by firstly investigating the common behaviors of video noises and observing two important characteristics: 1) downscaling helps to reduce the noise level in spatial space and 2) the information from the adjacent frames help to remove the noise of current frame in temporal space. Motivated by these two observations, we propose a multi-scale recurrent architecture by making full use of the above two characteristics. Secondly, we propose a synthetic real noise degradation model by randomly shuffling different noise types to train the denoising model. With a synthesized and enriched degradation space, our degradation model can help to bridge the distribution gap between training data and real-world data. Extensive experiments demonstrate that our proposed method achieves the state-of-the-art performance and better generalization ability than existing methods on both synthetic Gaussian denoising and practical real video denoising.

1 Introduction

Video denoising, with the aim of reducing the noise from a video to recover a clean video, has drawn increasing attention in low-level computer vision community [42, 43, 45, 15, 10, 25, 31, 20, 6, 7, 5]. Compared with image denoising, video denoising remains large underexplored domain. With the advance of deep learning [37, 58, 53], deep neural networks (DNNs) [45, 43, 40] have become the dominant approach for video denoising. To push the envelope of video denoising, existing DNNs-based methods mainly focus on two directions with the some assumptions.

Firstly, a line of studies [42, 43] assume noisy videos are the addition of white Gaussian noises (AWGN) to clean videos. These methods perform well when tested on videos with the same degradation setting. However, their performance would deteriorates significantly when tested on videos corrupted by other types of noises (e.g., video compression noise and camera sensor noise) due to the noise distribution mismatch [54]. To handle these noises, it is impractical to train multiple models. Moreover, noises in real-world videos are even more complex. Nevertheless, it is fair and necessary to train with AWGN and evaluate the effectiveness of different denoising methods in this simplified setup as a start point.
Secondly, to relieve the degradation mismatch between synthetic training data and real videos, the other line of work [13] proposed to capture noisy-clean video pairs for training. However, the video capturing and alignment process is time-consuming and expensive, which limits the potential size of such datasets. Another important limitation is that the training data is often captured by one specific camera, the degradation distribution of which may differ far away from other cameras under other recording environments. Therefore, deep models [13] trained on such clean-noisy paired videos can suffer from poor generalization performance when tested on data collected from other cameras.

However, these two assumptions only consider limited types of degradations which rarely happen in real noisy videos. Such degradation mismatch between training videos and real test videos would inevitably give rise to poor generalization performance. To address this, we focus on a more general video denoising setup with the goal to train a deep model to generalize well to unseen real-world videos, different from existing studies illustrated in Figure 2. To tackle this problem, we first take a closer look on the inherent properties of noisy videos in the spatial and temporal space. The statistics of clean patches in noisy images have been explored in some studies [60]. However, there are little work devoted to the analysis of noisy videos. In Figure 1, we observe that downscaling can reduce part of noise for different levels. Motivated by this observation, we propose to integrate multi-scale learnable downscaling into the denoising network. On the other hand, noise in a video often has random patterns in temporal space. Some pixels in current frame may have much more noise, while pixels in the same position of adjacent frames can have less noise, as shown in Figure 1 (b). To restore clean videos, it is necessary to model temporal connections so as to utilize information from adjacent frames to remove noise in the current frame.

Motivated by these two properties, we design a new architecture for general real video denoising, which we refer to as ReViD. ReViD consists of multiple scales, each of which has learnable downscaling to remove spatial noise and recurrent modeling to separate temporal signal from a noisy video. To handle the degradation mismatch between training data and real-world test videos, we propose a new degradation model to generate diverse noisy video and bridge the distribution gap by using a randomized composition of a wide range of degradations.

The contributions of this paper can be summarized as follows:

- We design a simple but effective real video denoising network by exploiting the inherent properties of a noisy video. Our method achieves the state-of-the-art performance on additive white Gaussian denoising and real-world video denoising tasks.
- We make the first attempt for general real video denoising and propose a new noise degradation model. Our degradation model is able to generalize well on unseen and complex real-world videos. Moreover, we provide a theoretical analysis that training with our degradation model is equivalent to regularized loss with strong penalty. Our degradation model can generate diverse noisy video with large variance to better match the distribution of real-world videos.
- We conduct extensive experiments to demonstrate the effectiveness and superiority of our proposed method on both synthetic Gaussian denoising and practical real video denoising. We propose a new real video denoising test dataset consisting of different real-world noises. Our dataset can serve as a real video denoising benchmark for further studies.
2 Related Work

**Image denoising.** The goal of image denoising is to reduce noise from a noisy image [22, 16, 29, 3]. The well-known BM3D [14] uses the block-matching and the collaborative filtering in a 3D transform domain. Alternatively, NLB [24] proposes a non-local Bayesian image denoising algorithm. However, the performance of these methods depend highly on the specific forms of prior and hand-tuned parameters in the optimization. They also lack flexibility as multiple models need to be trained for different levels of noise. To address this, recent methods exploit the benefits of deep neural networks. Results from continually improving neural networks have been demonstrating significant denoising performance enhancement. This includes convolution neural networks (CNNs) (e.g., DnCNNs [56], RBDN [39] and FFDNet [57]) and Transformer [28] (e.g., SwinIR [27] and SCUNet [54]). In addition, many image denoising models [36, 4, 11, 23] train on real image pairs [51, 18] captured by one camera. However, these methods often have poor performance on other cameras. While image based denoising methods can in theory construct a baseline for real-world blind video denoising by treating each frame as a separate image, directly using them in our setup ignores the fruitful temporal connections between different frames in a video and leads to relatively poor performance.

**Video denoising.** Video denoising aims at removing noise to synthesize clean video sequences. Based on BM3D [14], VBM4D [30] presents a video filtering algorithm to exploit temporal and spatial redundancy of the video sequence. Some existing methods make use of the Recurrent Neural Network (RNN) to capture this sequential information. DRNNs [12] first applies deep RNN for video denoising on the grady-scale images. However, the method seems to have difficulty to be extended to RGB images probably due to the difficulties of training RNN [35]. Recently, BasicVSR++ [8] improves the second-order grid propagation and flow-guided deformable alignment in RNN and extends video super-resolution to the video denoising [10]. In addition, some denoising methods adopt an asymmetric loss function [48] to optimize the networks, or propose patch-based video denoising algorithm [1, 15] to exploit the correlations among patches. For example, VNLB [1] is a patch-based empirical Bayesian video denoising algorithm. VNLNet [15] combines a patch-based framework with DnCNN [56] architecture by proposing a non-local patch search module in video denoising and fusing features by CNN. PaCNet [46] combines a patch-based framework with CNN by augmenting video sequences with patch-craft frames and inputting them in a CNN. To further improve over patch-based methods, DVDnet [42] proposes spatial and temporal denoising blocks and trains them separately. To boost the efficiency, FastDVDnet [43] extends DVDnet [42] by using two denoising steps in the architecture which composed of a modified multi-scale U-Net [38], and it achieves fast runtimes. VRT [26] proposes a video restoration transformer with parallel frame prediction, and achieves the state-of-the-art performance in video denoising. However, this transformer-based method has a large model size and expensive computational cost. Moreover, the above methods cannot be directly used in our real-world video denoising setup as they only consider synthesized gaussian noise. Recently, ViDeNN [13] proposes a blind video denoising method trained either on AWGN noise or on collected real-world videos. However, this method may have limited generalization ability as the training only considers the specific noise type presented in the training dataset. This can lead to potential issue when tested on different real-world videos captured from different sensors under different conditions.
We show how common properties of video noises can benefit network design in video denoising. The model trained with collected dataset from one camera has poor performance on other cameras. Training with Gaussian distribution cannot generalize well to most areas of the real distributions. (c) Our noise degradation aims to synthesize large amounts of data to match the real distribution.

3 Proposed Method

3.1 General Real Video Denoising

In digital video processing, a noisy video can be corrupted by some random process. Formally, given a clean video sequence $x$, a noisy video $x_\sigma$ can be obtained by additive noises, i.e., $x_\sigma = x + z_\sigma$, where $z_\sigma$ is a variable sampled from some distribution with density $p(\sigma)$. For traditional gaussian denoising, this distribution is a zero-mean Gaussian distribution with standard deviation $\sigma$, i.e., $\mathcal{N}(0, \sigma I)$, where $\sigma$ represents the noise level in a video. However, real-world video noises are mostly unknown and can differ between different videos due to differences in cameras, imaging setups, environments, etc.

To improve the denoising performance on videos with unknown noises, we generalize the assumption on noises and do not assume any pre-defined noise type. We call this new setup General Real Video Denoising. As shown in Figure 2, unlike previous blind video denoising methods [13] which implicitly assume that the training and test data share the same noises, our proposed setup is more generalizable and can be tested on videos with unknown noises. Formally, our goal is to learn a video denoiser $f_{\sigma}$ to reduce noise and synthesize clean video sequence by minimizing the following problem, i.e.,

$$f_\sigma = \arg \min_f \mathcal{L}_{\sigma}(f) := \mathbb{E}_{\sigma \in \pi(\sigma)} \left[ \mathbb{E}_{x \sim x(\sigma)} \left[ \| f(x_\sigma) - x \|^2 \right] \right],$$

(1)

where $\mathbb{E}[]$ is an expectation w.r.t. the data or the noise distribution. To understand how to train a denoiser for testing videos with unknown noises, we first provide a Lemma motivated by [17].

**Lemma 1** Assume that the training distribution $\pi$ and testing distribution $p$ are partly overlapped, let $f_p = \arg \min_f \mathcal{L}_{\pi}(f)$. The risk of $f_p$ is bounded by: $\mathcal{L}_{p}(f_p) \leq \mathcal{L}_{p}(f_\pi), \forall \pi$.

From this lemma, we can minimize Equation (1) such that the generalization error becomes small as long as $\pi$ and $p$ are partly overlapped. For traditional Gaussian denoising problem which considers multiple noise levels $\sigma$, this is achievable by training a denoiser using all noise levels, because the testing distribution $p$ will be on a specific noise level and $p$ is then a subset of the training distribution $\pi$, therefore overlapped. For our proposed general real video denoising problem, it is more complicated as the testing distribution $p$ is unknown. To minimize the generalization error, we need to build a new noise degradation for training such that the training distribution $\pi$ can be partly overlapped with the unknown test distribution $p$. An illustration of the difference between gaussian, blind, and our proposed general real denoising is provided in Figure 3.

Motivated by Lemma 1, we propose a new video denoising method that aims to tackle the general real video denoising problem. In this section, we first show how video noise properties can be exploited for network design to facilitate the optimization. We then propose a video degradation model to make the distributions of training data $\pi$ match better with real test videos $p$.

3.2 Multi-Scale Recurrent Network for Video Denoising

We show how common properties of video noises can benefit network design in video denoising. The proposed architecture is provided in Figure 4.

**Denoising in the spatial space.** As shown in Figure 1 (a), simple downscaling (e.g., bicubic) can suppress specific noises (e.g., Gaussian noise). However, simple downscaling is hard to handle more
Figure 4: The architecture of the proposed multi-scale recurrent network. Our network is motivated by video noise properties. For non-blind video denoising, we take the noisy video and noise level map as an input. For general real video denoising, we feed the noisy video augmented by our degradation models to train the network. At each scale, the network first removes spatial noise with learnable ResNet downscaling blocks and then removes temporal noise using a recurrent structure.

complex noises (e.g., combination of different kinds of noises) in real-world videos and can also induce the serious blur artifacts. Therefore, we introduce a learnable convolution to downscale features to reduce different kinds of noise. Specifically, given an $n$-frame noisy video $x_n$, we first deploy a convolutional layer to extract low-level features $\{g_1, \ldots, g_n\}$. Here, $x_0$ is an input image which combines the noisy video and the level map of the additive white Gaussian noise (AWGN) for traditional denoising problem. For real video denoising, $x_0$ is augmented by our proposed noise degradation model which is discussed in the next section. Then, we use a spatial encoder $E_{\text{spatial}}$ to extract deep features and reduce the noise in space, i.e.,

$$g_i^s = E_{\text{spatial}} (g_i^{s-1}),$$  \hspace{1cm} (2)

where $g_i^s = \hat{g}_i$, and the spatial encoder $E_{\text{spatial}}$ can be modelled by multi-layered residual blocks.

Denoising in the temporal space. Motivated by the temporal property and [8], we follow the second-order Markov chain to propagate the features. Given a denoised spatial feature $g_i^s$, we use the optical-flow-guided deformable alignment as our temporal encoder $E_{\text{temporal}}$ to compute the features

$$\hat{f}_{i,j} = E_{\text{temporal}} \left( g_i^s, f_{i-1,j}, f_{i-2,j}, o_{i \to i-1}, o_{i \to i-2} \right),$$  \hspace{1cm} (3)

where $f_{i,j}$ is the feature at the $i$-th timestep in the $j$-th propagation branch at the $s$-th scale, and $o_{i \to i-2}$ is the optical flow from the $i_2$-th frame to the $i_1$-th frame at the $s$-th scale. In practice, we implement $E_{\text{temporal}}$ by using the architecture of the flow-guided deformable alignment of [8] to predict offset and mask in DCN [59]. More details are provided in the Supplementary. After reducing the temporal noise, we use another spatial encoder $E_{\text{spatial}}$ to further remove the noise in space, i.e.,

$$f_{i,j} = f_{i,j}^s + E_{\text{spatial}} \left( f_{i,j}^{s-1} \right),$$  \hspace{1cm} (4)

where $[\cdot: \cdot]$ is a concatenation along the channel dimension and $f_{i,0}^s = g_i^s$. Let $f_{i}^s$ be the feature in the last branch at the $s$-th scale, the spatial decoder $D_{\text{spatial}}$ aggregates features with the skip connection,

$$h_i^s = f_i^s + D_{\text{spatial}} (h_i^{s+1}),$$  \hspace{1cm} (5)

where $h_i^S = f_i^S$ at the last scale $S$ and spatial decoder can be implemented by multi-layered residual blocks [19] with PixelShuffle [41] in the experiment. Last, we use convolutional layers to produce residual noise. In the training, we first train a denoiser using L1 loss, and then we further train the model by minimizing a weighted combination of L1 loss, perceptual loss and GAN loss.

3.3 Real Noise Degradations

Unlike Gaussian noises in traditional setups, real-world videos often contains unknown noises and blur and they differ from video to video. They are more complex and also harder to collect. A denoiser trained on one noise distribution can have poor generalization on real-world video noise because of the distribution mismatch between the training and test. Following the guidance from Lemma 1, we propose a general video denoising method with a new noise degradation for real-world videos. Different from traditional methods which directly reducing noise, the general video denoising is more practical because it is able to learn a residual and jointly remove noises and blur.

To better model real-world distribution, we propose to use randomized combination of a wide range of degradation types. Specifically, we randomly change the order of different degradations in the training. The distribution of training data augmented with the proposed randomized degradations can...
Apart from noise, most real-world videos inherently suffer from bluriness. Thus, we additionally consider two common blur degradations, including Gaussian blur and resizing blur. For Gaussian blur, we synthesize a video as \( g_\kappa(x) = x * \kappa \), where \(*\) is the convolution operator and \( \kappa \) is the Gaussian kernel. For resizing blur, we first downscale a video for \( s \times \) and then upscale to the original size, \( \text{i.e.}, g_s(x) = \text{up}_s(\text{down}_\frac{1}{2}(x)) \), where \( \text{down}_\frac{1}{2} \) and \( \text{up}_s \) are downscaling and upscaling function.

\[ x_\sigma = g(x) = (g_{i_1} \circ g_{i_2} \circ \cdots \circ g_{i_N})(x), \quad \text{where} \quad \{i_1, \ldots, i_N\} = \phi(\{1, \ldots, N\}), \quad (6) \]

where \( \phi \) is a shuffle function, \( \circ \) is a function composition, and \( g_{i_n} \) is a degradation model of the \( i_n \)-th type. Motivated by [2], we prove the following theorem to understand our degradation.

**Theorem 1 (Effect of noise degradations)** Let \( z_\sigma = g(x) - x \), and assume that the mean and variance of the noise distribution are 0 and \( \eta^2(z_\sigma) \), then the loss (1), i.e.,

\[
\mathbb{E}_x \left[ \mathbb{E}(z) \left[ \|f(x_\sigma) - x\|^2 \right] \right] = \mathbb{E}_x \left[ \|f(x) - x\|^2 \right] + \eta^2(z_\sigma) \mathbb{E}_x \left[ \left( \| \frac{\partial f(x)}{\partial x} \| + \frac{1}{2} (f(x) - x)^T \frac{\partial^2 f(x)}{\partial x^2} 1 \right) \right]. \quad (7)
\]

Figure 5: An illustration of the proposed noise degradation pipeline. For a high quality video, a randomly shuffled degradation sequence is performed to produce a noisy video.

From this theorem, the loss (1) trained with our noise degradations is equivalent to a normal loss with a regularization term. The parameter \( \eta^2(z_\sigma) \) is related to the amplitude or variance of the noise \( z_\sigma \) and controls how the regularization term influences the loss. Moreover, our degradation model makes \( \eta^2(z_\sigma) \) to be large (see Figure 11) to improve the generalization performance of our model.

**Noise.** Noises in real-world videos come from different sources. To simulate such noises, we propose noise degradations, including Gaussian noise, Poisson noise, Speckle noise, Processed camera sensor noise, JPEG compression noise and video compression noise.

- **Gaussian noise.** When there are no prior information of noise, one can add Gaussian noise into a video sequence. Such Gaussian noise can be additive white Gaussian noise (AWGN) and gray-scale AWGN. Given a clean video \( x \), the noisy video can be synthesized by additive noise \( z \), i.e., \( g_1(x) = x + z \), where the noise \( z \) can be sampled from \( \text{AWGN } N(0, \sigma I) \) and gray-scale AWGN \( N(0, \sigma I) \). Here, \( \sigma \) is a covariance, \( I \) is an identity matrix and \( I \) is a \( 3 \times 3 \) all-ones matrix.

- **Poisson noise.** In electronics, Poisson noise is a type of shot noise which occurs in photon counting in optical devices. Such noise arises from the discrete nature of electric charge, and it can be modeled by a Poisson process. Given a clean video \( x \), we synthesize a noisy video by \( g_2(x) = x + z \), where \( z \sim \mathcal{P}(10^9 \cdot x)/10^9 \).

- **Speckle noise.** Speckle noise exists in the synthetic aperture radar (SAR), medical ultrasound and optical coherence tomography images. We simulate such noise by multiplying the clean image \( x \) and Gaussian noise \( z \), i.e., \( x * z \). Then, we synthesize noisy video by \( g_3(x) = x + x * z \).

- **Processed camera sensor noise.** In modern digital cameras, the processed camera sensor noise originates from the image signal processing (ISP). Inspired by [54], the reverse ISP pipeline first get the raw image from an RGB image, then the forward pipeline constructs noisy raw image by adding noise to the raw image, which denoted by \( g_4(x) = \text{forward} (\text{reverse} (x)) \).

- **JPEG compression noise.** It is widely used to reduce the storage for digital images with the fast encoding and decoding [55]. We denote the synthesized frames with JPEG compression noise by \( g_5(x) = \text{Dec} (\text{Enc} (x)) \). Such JPEG compression methods often cause \( 8 \times 8 \) blocking artifacts.

- **Video compression noise.** Videos sometimes have compression artifact and presents on videos encoded in different format. We use the Pythonic operator av in FFmpeg, i.e., \( g_6(x) = \text{av} (x) \). Apart from noise, most real-world videos inherently suffer from bluriness. Thus, we additionally consider two common blur degradations, including Gaussian blur and resizing blur. For Gaussian blur, we synthesize a video as \( g_\kappa(x) = x * \kappa \), where \(*\) is the convolution operator and \( \kappa \) is the Gaussian kernel. For resizing blur, we first downscale a video for \( s \times \) and then upscale to the original size, i.e., \( g_s(x) = \text{up}_s(\text{down}_\frac{1}{2}(x)) \), where \( \text{down}_\frac{1}{2} \) and \( \text{up}_s \) are downscaling and upscaling function.

Figure 6: Visual comparison of different methods on DAVIS [21] under the noise level of 50.

Figure 7: Runtime, PSNR, and model size.

4 Experiments

4.1 Synthetic Gaussian Denoising

**Datasets.** We use DAVIS [21] and Set8 [42] in synthetic Gaussian denoising. Following the setting of [26], we synthesize the noisy video sequences by adding AWGN with noise level \( \sigma \in [0, 50] \) on the DAVIS [21] training set. We then train the model by using the synthesized data and test it on the DAVIS testing set and Set8 [42] with different Gaussian noise levels \{10, 20, 30, 40, 50\}.

**Quantitative comparison.** Tables 1-3 show quantitative comparison of PSNR [8] between different methods on the test datasets DAVIS [21] and Set8 [42]. Our method has best performance on both DAVIS and Set8 with a large margin. Specifically, our model outperforms BasicVSR++ [10] by an average PSNR of **1.21db** and **1.24db** on DAVIS and Set8, respectively. Moreover, we also train a blind model for clipped AWGN to obtain the best performance. In Figure 7, our model achieves the best performance gains with similar model size and runtime. In particular, for the largest noise level of 50, our model outperforms VRT [26] with a smaller model size and faster inference time. Our model yields a PSNR improvement of **0.54db** and **0.55db** on DAVIS and Set8, respectively.
Table 4: Quantitative Comparison of different methods on VideoLQ and NoisyCity4 for the practical video denoising task. For fair comparison, we train BasicVSR++ and RealBasicVSR on the same proposed noise degradation pipeline, which is denoted by suffix ‘∗’.

| Methods                 | VideoLQ       | NoisyCity4    |
|-------------------------|---------------|---------------|
|                         | NIQE ↓ | BRISQUE ↓ | PIQE ↓ | NIQE ↓ | BRISQUE ↓ | PIQE ↓ |
| SCUNet [54]             | 4.7797 | 39.6360 | 68.7677 | 5.1971 | 51.5672 | 85.2371 |
| Restormer [52]          | 4.3755 | 39.9023 | 69.6296 | 5.1884 | 52.7126 | 86.2248 |
| ViDeNN [13]             | 4.2722 | 33.8539 | 60.7876 | 4.7613 | 42.5865 | 78.9111 |
| BasicVSR++ [8]          | 4.0233 | 34.9458 | 51.4780 | 5.4899 | 52.1469 | 81.1234 |
| BasicVSR++∗ [8]         | 4.2879 | 29.1541 | 49.1658 | 4.4235 | 33.4198 | 47.5131 |
| RealBasicVSR∗ [9]       | 4.2167 | 29.2103 | 48.0369 | 4.0578 | 26.3504 | 51.5825 |
| ReViD-real              | 4.0205 | 29.0212 | 45.0768 | 3.8540 | 24.2025 | 48.2962 |

Figure 8: Visual comparison of different video denoising methods on NoisyCity4.

Qualitative comparison. In Figure 6, we provide the visual comparisons of different video denoising methods under the high noise level of 50. Our proposed denoiser restores better structures and preserves clean edge than previous state-of-the-art video denoising methods, even though the noise level is high. In particular, our model is able to restore the letters ‘Gebr’ in the first example and piano texture in the second example of Figure 6. In contrast, VBM4D [30], DVDnet [42] and FastDVDnet [43] fail to remove severe noise from a video frame. BasicVSR++ [8] and VRT [26] only restore part of the textures.

4.2 General Real Video Denoising

For real video denoising, we use REDS [34] as the training set. According to the setting of [49], we use 266 regrouped training clips in REDS [34], where each with 100 consecutive frames. Specifically, we synthesize noisy video sequences on the REDS training set by using our proposed noise degradation model. To evaluate the generalizability of real-world video denoising methods, one can use VideoLQ [9] which is downloaded from Flickr and YouTube and contains 50 video sequences, where each with up to 100 frames. However, the VideoLQ dataset was mainly proposed for real-world video super-resolution and it has low level of noise itself. To address this, we additionally propose a new benchmark dataset for real-world video denoising, called NoisyCity4 dataset. This dataset is collected from YouTube and contains four city street videos from decades ago. The videos in the proposed dataset contain real-world noises from different sources such as film grains, film scratches, flickers etc. Examples of the NoisyCity4 videos are shown in Figure 9 and further provided in the supplementary material. Each video in NoisyCity4 contains a sequence of 100 frames with different noises.

Figure 9: Examples of the NoisyCity4 dataset.
Quantitative comparison. Table 4 provides the quantitative comparison of different methods on VideoLQ [9] and NoisyCity4. Here, we use three non-reference metrics NIQE [33], BRISQUE [32] and PIQE [47] as evaluation metrics because they are commonly used to measure the quality of images and ground-truth videos are not available. Our model achieves better performance than all other methods under all metrics. In contrast, it is difficult for ViDeNN to reduce noise in real video since the videos are captured by different cameras. With the help of our noise degradation model, the denoisers are able to reduce the real-world noise.

Qualitative comparison. As shown in Figure 8, our model achieves the best visual quality among different methods. By taking the spatial and temporal properties into account and using the proposed noise degradation model, our denoiser improves visual quality and leads to cleaner details and edges than other methods. For instance, our model is able to recover the windows in the building. In contrast, it is hard for image based denoisers [52, 54] and ViDeNN [13] to remove the noise well in a real-world video. There results demonstrate our degradation model is able to improve the generalization ability.

### 4.3 Further Experiments

**Effect of our degradation model.** To study the effect of our degradation model, we show the distributions of the synthesized noise by our degradation model with and without the proposed random shuffle in Figure 10. The random shuffle strategy can improve the diversity of the synthesized distributions. In addition, this strategy can increase the noise variance in Figure 11. This shows that the proposed method can generate more diverse distributions in the training.

**Ablation study.** We investigate the effectiveness of the spatial and temporal modules in Table 5. Specifically, we conduct experiments by removing these modules. The model without these modules has performance drop, which demonstrates the importance of them. In addition, we investigate the performance by increasing the times of downscaling to 3. The model has comparable PSNR but with larger model size. Thus, we downscale the videos twice in the experiment.

### 5 Conclusion

In this paper, we propose a practical and important setup in video denoising called general video denoising. Motivated by properties of video noises, we first propose a real video denoising network, called ReViD to achieve the state-of-the-art performance on synthetic Gaussian denoising and general real video denoising. Moreover, we make the first attempt to design a new noise degradation model for the real-world video denoising task which considers different kinds of noise with random shuffle. In addition, we propose a new real video denoising dataset with different levels of noise. Extensive experiments demonstrate the effectiveness and superiority of denoising and practicability of our method. Besides, our model has good generalization performance on unseen real videos.
