Abstract

We give a short overview of the theory of the muon anomalous magnetic moment with emphasis on the hadronic light-by-light and the pion loop contribution. We explain the difference between the hidden local symmetry and full VMD pion loop and discuss leading logarithms in the anomalous sector of 2-flavour chiral perturbation theory.

∗ Invited talk presented by JB at MESON2012 - 12th International Workshop on Meson Production, Properties and Interaction, Krakow, Poland, 31 May – 5 June 2012
Abstract. We give a short overview of the theory of the muon anomalous magnetic moment with emphasis on the hadronic light-by-light and the pion loop contribution. We explain the difference between the hidden local symmetry and full VMD pion loop and discuss leading logarithms in the anomalous sector of 2-flavour chiral perturbation theory.

1 The muon anomalous magnetic moment

In this section we give a short overview of the present status of the theory behind the muon anomalous magnetic moment and a few new results on the pion loop contribution to the light-by-light part.

Experiment and theory use the anomaly $a_{\mu} \equiv (g_{\mu} - 2)/2$. BNL E821 [1] dominates the world average [2] given in Tab. 1. The standard model prediction is a bit off. The prediction and its main parts are listed in Table 1. For definiteness we quote numbers and errors of [2], but there is agreement on all numbers except on the hadronic light-by-light (HLBL) part. The difference is given in the last line of Tab. 1 with errors added quadratically. The experiment will move to Fermilab with an expected improvement of a factor of four. Theory thus needs to improve. The discrepancy has created a lot of excitement since many BSM models can predict a value in this range but often a lot more or a lot less. The value of $a_{\mu}$ provides a major constraint on many BSM models. Reviews of all aspects are [3,4].

1.1 QED, Electroweak and Hadronic Vacuum Polarization

The QED contribution is well known. The first term is due to Schwinger. The first three terms are known analytically. The fourth is a full numerical calculation and the fifth is an estimate. With $\bar{\alpha} = \alpha/\pi$,

$$a_{\mu}^{\text{QED}} = 0.5 \bar{\alpha} + 0.765857410(27) \bar{\alpha}^2 + 24.05050964(43) \bar{\alpha}^2 + 130.8055(80) \bar{\alpha}^2 + 663(20) \bar{\alpha}^2 + \cdots$$

Kinoshita and collaborators played a major role in evaluating all contributions numerically. The QED value in Tab. 1 uses $\alpha$ from the electron magnetic moment. The third order contribution is dominated by the unexpectedly large leptonic light-by-light (LLBL) contribution [5]. The Schwinger diagram is shown in Fig. 1a and the LLBL diagram in Fig. 1b with its part of the 24.05 QED third order in $\bar{\alpha}$.

A typical one-loop electroweak diagram is Fig. 2a. Two-loop corrections are large due to large, partly hadronic, logarithms in diagrams like Fig. 2b, (triangle) anomaly in (muon) anomaly [8,9].

$$10^{10} a_{\mu}^{\text{EW}} = 19.48[1\text{-loop}] - 4.07(0.10)(0.18)[2\text{-loop}] = 15.4(0.1)(0.2)(\text{triangle})(\text{Higgs mass}).$$

The remaining relevant contributions in the standard model are all hadronic. The largest is the hadronic vacuum polarization (HVP). The bare quark-loop has large gluonic corrections and needs to
Table 1. Overview of results.

Fig. 4. A diagram with two insertions of the HVP.

be done to all orders in $\alpha_S$ as depicted in Fig. 3. This contribution can be related to experiment via

$$a_\mu^{\text{1.ohad}} = \frac{1}{3} \left( \frac{\alpha}{\pi} \right)^2 \int_{2\pi}^\infty ds \frac{K(s)}{s} R^{(0)}(s), \quad R^{(0)}(s) \equiv \frac{\sigma(e^+e^- \to \text{hadrons})}{\sigma(e^+e^- \to \mu^+\mu^-)}|_{\text{bare}}.$$

(3)

The precise definition of bare led to some confusion between theory and experiment and there were experimental discrepancies. A representative value is given in Tab. 1. see [2,3,4] for references and discussion. At higher orders in $\alpha$ two types of hadronic contributions are relevant. Those with two insertions of the HVP, as in Fig. 4 see [2,3,4], can be evaluated from $R^{(0)}(s)$ and the HLBL contribution is discussed in Sect. 1.2. Values are again given in Tab. 1.

1.2 Hadronic Light-by-Light

The HLBL contribution is depicted in Fig. 5. The muon and photon lines are the well known part. The blob needs to be filled with hadrons and QCD. The trouble is that low- and high-energy are very mixed and a double counting of different hadron/quark contributions needs to be avoided. A workshop at INT, Seattle [10] provides a good overview of the situation. A start on separating the different parts is by studying at which orders in the large number of colours, $N_c$, and chiral, $p$, expansion, contributions start [11]. The pion loop is $1$, $p^3$, pion-exchange is $N_c$, $p^6$ and all others start at $N_c$, $p^8$. This separation was used to do a full calculation by two independent groups, [6] and [12]. The latter
used purely hadronic exchanges and added a quark-loop with a VMD suppression as well as the pion loop in hidden local symmetry (HLS) model. They studied the dependence on the vector meson mass to determine the important energy regions. The former used the extended Nambu-Jona-Lasinio model of ENJL as a basis while repairing its worst shortcomings. The advantage is that this model has quarks and automatically generates pseudo-scalars, vectors and axial-vectors with a reasonable description. The contribution of type $X$ at a given scale $P_1$, $P_2$, $Q$ are directly proportional to the volume under the surface when $a_{\mu}^{XLL}$ and $a_{\mu}^{XLLO}$ are plotted versus the energies on a logarithmic scale.

The main contribution is pseudo-scalar exchange, $\pi^0$ (and $\eta, \eta'$), depicted in Fig. 6. Here one has to model the form-factor $F(q^2, k_1^2, k_2^2)$ including the dependence on how off-shell the pion is. Treating it is pointlike gives a logarithmic divergence which can be evaluated using chiral perturbation theory (ChPT). The $\pi^0$-exchange was found to be essentially saturated at a scale of 1 GeV and $10^{10}a_{\mu}^{XLO} = 5.9$. Including $\eta, \eta'$ exchange leads to the value listed under pseudo-scalar and BPP in Tab. 2. All models except 20 give basically a common value for $10^{10}a_{\mu}^{XLO}$ with 6.27 for the

---

**Fig. 5.** The hadronic light-by-light (HLBL) contribution to $a_{\mu}$.

**Fig. 6.** The pseudo-scalar exchange diagram. The blobs denote the form-factor $F(q^2, k_1^2, k_2^2)$.

**Fig. 7.** The tree level diagrams that contract to the axial vector current in the limit $P_1^2 = P_2^2 \gg Q^2$. 

The HLBL contribution in all detail is given by, momenta and indices as in Fig. 5.

$$a_{\mu}^{HLBL} = \frac{e^6}{48m_{\mu}^2} \text{tr} \int d^4p_1 d^4p_2 \frac{\gamma_5(p_1 + m_{\mu})\gamma_\mu(p_2 + m_{\mu})\gamma_\nu}{(2\pi)^3} \frac{\delta\Pi^{\mu\nu}\delta\Pi^{\nu\mu}}{\delta p_{1\lambda}} (p_1 + m_{\mu})(\gamma_\lambda)(p_2 + m_{\mu})$$

The main object is the four point function of four electromagnetic currents $V_{\mu}(x) \equiv \sum Q_i [\bar{q}_i(x)\gamma_\mu q_i(x)]$.

$$\Pi^{\mu\nu}(p_1, p_2, p_3) \equiv i^3 \int d^4x \int d^4y \int d^4z e^{i(p_1 - x + p_2 - y + p_3 - z)} \langle 0\mid T\left(\bar{V}_{\mu}^{\nu}(0)\bar{V}_{\nu}^{\mu}(x)v_{\nu}(y)v_{\mu}(z)\right)\rangle$$

and we used $\Pi^{\mu\nu\lambda\nu\lambda}(p_1, p_2, p_3) = -p_{3\lambda}\delta\Pi^{\mu\nu\lambda\nu\lambda}(p_1, p_2, p_3)\delta\Pi^{\nu\mu\lambda\nu\lambda}$ which allows to calculate directly at $p_3 = 0$ and makes the integrals more convergent.

The general $\Pi^{\mu\nu\lambda\nu\lambda}$ is 138 different Lorentz structures of which 32 contribute to $a_{\mu}$ [6]. Using the gauge invariance relations $q_\mu\Pi^{\mu\nu\lambda\nu\lambda} = p_{1\lambda}\Pi^{\nu\mu\nu\lambda\lambda\lambda} = p_{2\lambda}\Pi^{\nu\mu\nu\lambda\lambda\lambda\lambda\lambda} = 0$ the 132 can be reduced to 43 structures that after $p_3 \rightarrow 0$ depend on $p_1^2$, $p_2^2$, $q^2$. There are 8 integrals in (4) and most evaluations have rotated the integrations to Euclidean space. Artefacts in models are smeared out there and the separation of long and short distances becomes easier. Three of the integrals are trivial and a new development is that of the remaining five two can be done using the Gegenbauer polynomial techniques [4,15,17]. So in the end integrals over $P_1^2 = -p_1^2$, $P_2^2 = -p_2^2$, $Q^2 = -q^2$ remain.

To visually see the contribution of various quantities different scales we introduce

$$a_{\mu}^{XLL} = \int dl_{P_1} dl_{P_2} a_{\mu}^{XLL} = \int dl_{P_1} dl_{P_2} dl_{Q} a_{\mu}^{XLL}, \quad \text{with} \quad l_P = \ln(P/GeV).$$

The contributions of type $X$ at a given scale $P_1, P_2, Q$ are directly proportional to the volume under the surface when $a_{\mu}^{XLL}$ and $a_{\mu}^{XLLO}$ are plotted versus the energies on a logarithmic scale.
nonlocal quark model \cite{21}, 5.75 for a Dyson-Schwinger equations based approach \cite{22}, (5.8 – 6.3) for a hadronic modeling with two vectors and some short-distance constraints \cite{15}, 6.54 for a form-factor inspired by AdS/QCD \cite{23}, (6.5 – 7.1) for the chiral quark model \cite{24}, 7.2 ± 1.2 with an extra constraint on the form-factor \cite{25} and 7.5 from a direct AdS/QCD calculation including pion excitations \cite{26}.

A new development was the short-distance constraint on the region $P_1 \approx P_2 \ll Q$ by \cite{20}. Here one uses the operator product expansion of two vector currents to relate $I_{\rho \nu}^{\mu \nu}$ to a matrix-element of an axial current. \cite{20} implemented this constraint by setting one of the form-factors in Fig. 6 to 1, i.e. pointlike. They obtained a value of $10^{10} a^{\mu \nu}_{\rho \nu} = 7.7$ which with including $\eta, \eta'$ leads to the number in Tab. 2 quoted under pseudo-scalar and PdRV. The OPE expansion comes from the diagrams of Fig. 7 so one expects that approaches involving the (short-distance) quark-loop do include this. \cite{7,21}. The distribution over energy scales for the two cases is shown in Figs. 5 and 7 of \cite{16}.

Axial-vector exchange is treated in the same way. \cite{20} found an enhancement over \cite{6} from both their short-distance constraint and the mixing of the two axial-vector nonets giving the di...

Fig. 8. The momentum distribution of the pure quark-loop contribution for various ratios of $P_2/P_1$.

Fig. 9. The momentum distribution of the bare and the pure VMD pion-loop contribution for $P_2 = P_1$.

The last contribution is the one leading in ChPT, the charged pion, and a small kaon, loop. The bare pion loop gives a large contribution of $10^{10} a_{\rho \nu}^{\mu \nu}$ = −4.1 but this is expected to be too large. Several chirally invariant models were used, the HLS approach \cite{12} which gave −0.45 and the VMD inspired approach \cite{6} which gave −1.9, an exact VMD approach gives −1.6 \cite{6,12,17}. One can derive from the OPE of two vector currents also a short-distance relation for the $\gamma^* \gamma' \pi \pi$ process which the HLS and the bare vertex do not satisfy while the VMD inspired approaches do \cite{17}. The distribution over momenta of the contributions is shown in Fig. 9 for the bare and the pure VMD case and in Fig. 10 for the HLS and pure VMD. Notice how the large momentum contributions are cut-off in both the VMD and HLS case and the source for the large difference between VMD and HLS is the negative contribution at larger momenta for the HLS indicating that the VMD result is probably more correct.

\cite{25} calculated the pion-loop four-point function $I_{\rho \nu}^{\mu \nu}$ at very low momenta in ChPT. They found that for $P_1, P_2, P_3, Q \ll m_\pi$ there are indications that the effect due to $L_8$ and $L_{10}$ which in the HLS and VMD models is only partially taken into account could be important. We show the pure VMD result with the pion loop result including the effect of $L_8$ and $L_{10}$ for scales up to 500 MeV in Fig. 11. We did not take the limit $P_1, P_2, P_3, Q \ll m_\pi$. One sees indeed an enhancement of 10% due $L_8, L_{10}$. The full contribution to $a_{\mu}$ at that order in ChPT is divergent.

We conclude like \cite{6,12,17} that $Q^{\text{HLS}} \approx (10 \pm 3) \cdot 10^{-10}$ where the exact central value and error are somewhat subjective.
same order and for the vector and scalar form-factors as well as meson-meson scattering to four-loops in [32]. [31,32] also discussed the large order all divergences must cancel. Using dimensional regularization with loops requires 303. The size of each diagram grows even faster. The leading logarithms for the mass for the massive vector form-factor were pushed to six loops in [33]. [33]s main purpose was including the anomaly proven using beta-functions [30] and diagrams [31]. The main underlying observation is that at leading logarithms can still be calculated from a one-loop calculation. The all order generalization was 2 Renormalization group for EFT showing extremely good convergence. The form-factor The leading logarithms, the terms logarithms are known to be only a small part. The nonfactorizable part two facts. The dependence of any observable on the subtraction scale by a running coupling. This can be proven directly from the renormalization group, but relies on the fact that in a renormalizable theory counter-terms are of the same form at every order. It implies that the leading logarithms are calculable by a one-loop calculation. The counter-terms for an e ultraviolet divergences in QFT are local. In renormalizable QFT leading logarithms can be described is there for on-shell photons; \( F(\kappa^2) \) is the form-factor for one o \( \pi \gamma \gamma \). The momentum distribution of the pure VMD and HLS pion-loop contribution for \( P_2 = P_1 \).  

Fig. 10. The momentum distribution of the pure VMD and HLS pion-loop contribution for \( P_2 = P_1 \).

Fig. 11. The momentum distribution of the pure VMD pion-loop and the bare pion loop with \( L_{00}, L_{10} \) effect included, contribution for \( P_2 = P_1 \).

\[ F(M) = F^0 + F^1_1 L + F^1_2 + \sum_{n=2,\alpha} \sum_{m=0} \frac{F^m_n L^m}{\mu^n}, \quad L = \ln(\mu/M). \] (7)

The leading logarithms, the terms \( F^m_n L^m \), are easier to calculate than the full result. This follows from two facts. The dependence of any observable on the subtraction scale \( \mu \) vanishes, \( \mu dF/d\mu = 0 \) and ultraviolet divergences in QFT are local. In renormalizable QFT leading logarithms can be described by a running coupling. This can be proven directly from the renormalization group, but relies on the fact that in a renormalizable theory counter-terms are of the same form at every order. It implies that the leading logarithms are calculable by a one-loop calculation. The counter-terms for an effective low-energy theory, e.g. ChPT, differ at every order. However, Weinberg [29] pointed out that the two-loop leading logarithms can still be calculated from a one-loop calculation. The all order generalization was proven using beta-functions [30] and diagrams [31]. The main underlying observation is that at \( n \)-loop order all divergences must cancel. Using dimensional regularization with \( d = 4 - \epsilon \) the coefficients of

\[ \{1/\mu^\epsilon, \log \mu/\mu^\epsilon, \log^2 \mu/\mu^{2\epsilon}, \ldots, \log^{n-1}/\mu^\epsilon\}; \{1/\mu^{n-1}, \log \mu/\mu^{n-2}, \log^{n-1}/\mu^{2\epsilon}\}; \ldots \] (8)
must cancel. The first set of conditions allows to prove that all leading logs can be determined from one-loop diagrams, the second set that the subleading logs can be had from two-loop diagrams, etc.

The observation [31] that the needed Lagrangians at each order do not need to be minimal, allows them to be computer generated. The number of diagrams increases fast with order, e.g. mass at six loops requires 303. The size of each diagram grows even faster. The leading logarithms for the mass in the massive \( O(N) \) model were calculated to five loops in [31] for the decay constant and vev to the limit for these quantities. The mass, decay constant and vector form-factor were pushed to six loops in [33]. [33]s main purpose was including the anomaly for the massive \( O(3) \) model, i.e. two-flavour ChPT. The amplitude for \( \pi^0 \to \gamma'(k_1)\gamma(k_2) \) is

\[ A_{\gamma'\gamma\gamma} = \epsilon_{\mu
u\rho} k_1^\mu(k_1) \epsilon_2^\alpha(k_2) k_1^\nu F_{\gamma'\gamma\gamma}(k_1^2, k_2^2), \quad F_{\gamma'\gamma\gamma}(k_1^2, k_2^2) = \frac{\epsilon^2}{4\pi^2 F_\pi} \tilde{F} F_\gamma(k_1^2) F_\gamma(k_2^2) F_{\gamma'\gamma}(k_1^2, k_2^2). \] (9)

\( \tilde{F} \) is there for on-shell photons; \( F_\gamma(k^2) \) is the form-factor for one off-shell photon and \( F_{\gamma'\gamma}(k_1^2, k_2^2) \) is the nonfactorizable part when both photons are off-shell. The leading logarithms to six loops [33] are numerically

\[ \tilde{F} = 1 + 0 - 0.000372 + 0.000088 + 0.000036 + 0.000009 + 0.0000002 + \cdots \] (10)

showing extremely good convergence. The form-factor \( F_\gamma(k^2) \) also converges well but here the leading logarithms are known to be only a small part. The nonfactorizable part \( F_{\gamma'\gamma} \) only starts at three-loop...
order (could have started at two) and in the chiral limit only starts at four-loops. The leading logarithms thus predict this part to be fairly small.

Similarly, the leading logarithms for the $\gamma 3\pi$ vertex are small and give a good convergence with

$$F_{0}^{\text{LL}} = (9.8 - 0.3 + 0.04 + 0.02 + 0.006 + 0.001 + \cdots) \text{GeV}^{-3}.$$  \hspace{1cm} (11)
