Abstract. We introduce a reaction–diffusion system with modified nonlinear functional responses. We first discuss the large-time behavior of positive solutions for the system. And then, for the corresponding steady-state system, we are concerned with the priori estimate, the existence of the nonconstant positive solutions as well as the bifurcations emitting from the positive constant equilibrium solution. Finally, we present some numerical examples to test the theoretical and computational analysis results. Meanwhile, we depict the trajectory graphs and spatiotemporal patterns to simulate the dynamics for the system. The numerical computations and simulated graphs imply that the available food resource for consumer is very likely not single.

Keywords: reaction–diffusion system, large-time behavior, positive solution, bifurcation, numerical and graphical analysis.

1 Introduction

Many ecological phenomena among different populations can be characterized or simulated by various mathematical models. By analyzing different kinds of mathematical models people may give scientific predictions and explanations on the dynamics of these models, and further, put forward reasonable projects corresponding to some ecological problems. In many kinds of ecological-mathematical models, the predator–prey model is a very important branch. Since the classical Lotka–Volterra ecological model [13] was introduced into investigations, the predator–prey-type models received extensively attentions. In recent decades, different kinds of predator–prey models have been established, and many great progress and valuable achievements have been made; see [4,6,9,20,22,23] for examples.

In predator–prey models, the functional responses are very important terms in describing the relations between predator and prey, they determine many dynamical properties

of the systems in some extent. Specifically, the functional response describes the change
of predation rate of predator capturing prey, that is, how the predator consuming prey
is dependent on the response terms. In large number of predator–prey models, the func-
tional responses are of prey-dependent type, such as the classical Lotka–Volterra-type
functional response, the Holling-type II (sometimes referred to as the Michaelis–Menten
functional response), III and IV functional responses, the Ivlev and inverse Ivlev func-
tional responses, etc. Taking these functions as the functional responses, a great many of
predator–prey models have been studied thoroughly, and quite a lot of important research
achievements have been given; see [1, 10, 18, 21, 24], etc.

The introduction of prey-dependent-type functional response is based on the assump-
tion that the predation rate of predator is only effected by prey, and the predators are
mutual noninterference within themselves. In fact, generally speaking, the phenomenon
in sharing or competing their foods always occurs during the process of predation. When
the population density of predator is high, the predation rate will decrease. Moreover,
as the well-known environmental paradox being proposed by Hairston, et al. [8] and
Rosenzweig [19], the type of functional responses gave rise to many strong controversies
among ecologists. Just in this situation, based on the Holling-type II functional response,
by a great deal of experimental and numerical analysis, Beddington [3] and DeAngelis et
al. [5] introduced a new type functional response, the predator–prey dependent functional
response $f(x) = bx/(a + x + cy)$, which is called the Beddington–DeAngelis-type
functional response, where $x$ and $y$ represent the predator and prey, respectively, and
$a$, $b$, $c$ are parameters. This type of functional response is very like with the Holling-
type II functional response, the only difference is that the Beddington–DeAngelis-type
functional response involves both prey and predator. Compared with the prey-dependent-
type functional responses, the predator–prey-dependent functional response not only re-
flects the mutual interference with predators, but also remains the merits of the ratio-
dependent functional responses. Moreover, it avoids some controversies induced by low
population density and better describes the predation effect of the predator versus prey. It
is just because of these reasons, different kinds of models with predator–prey-dependent
functional response have become a center topic in population dynamics.

Except the Beddington–DeAngelis-type functional response, another attentive preda-
tor–prey-dependent functional response $hx/y$ is called the Leslie–Gower-type functional
response, where $h$ is a constant. It was introduced by Leslie [11] and discussed jointly by
Leslie and Gower [12]. This functional response measures the self-consumption of preda-
tor when the foods are scarce, where the growth of predator population is of logistic form.
Since in actual ecological systems, the carrying capacity set by environmental resources is
proportional to prey abundance and the predators always try to survive by catching other
preys when their conventional food is short seriously, in such situations, the growth rate
of the predator would be affected. For this reason, Aziz-Alaoui [2] modified the logistic
form and proposed the Leslie–Gower-type functional response $hx/(a + y)$, where $a$ is
a positive constant and measures the environmental protection for predator. With such
a functional response, Aziz-Alaoui et al. studied some predator–prey models in spatially
homogeneous or inhomogeneous cases; see [7,15–17,25]. Based on and motivated by all
the above-mentioned, in this paper, we introduce the following nondimensional reaction–

http://www.journals.vu.lt/nonlinear-analysis
diffusion system

\[
\begin{align*}
\frac{\partial u}{\partial t} &= d_1 \Delta u + u \left( a - u - \frac{\alpha v}{c + u + mv} \right), \quad x \in \Omega, \quad t > 0, \\
\frac{\partial v}{\partial t} &= d_2 \Delta v + v \left( b - v - \frac{\beta v}{r + u} \right), \quad x \in \Omega, \quad t > 0, \\
\frac{\partial u}{\partial \nu} &= \frac{\partial v}{\partial \nu} = 0, \quad x \in \partial \Omega, \quad t > 0, \\
u(x, 0) &= u_0(x) \geq 0, \quad \neq 0, \quad x \in \Omega, \\
v(x, 0) &= v_0(x) \geq 0, \quad \neq 0, \quad x \in \Omega,
\end{align*}
\] (1)

with two modified predator–prey-dependent nonlinear functional responses \(\alpha v/(c + u + mv), \beta v/(r + u)\). Here \(\Omega\) is a bounded domain in \(\mathbb{R}^n\) with smooth boundary \(\partial \Omega\), \(u\) and \(v\) are the densities of prey and predator populations. \(d_1\), \(d_2\) and \(a\), \(b\) are the diffusion rates and the growth rates of \(u\) and \(v\), respectively; \(\alpha\) is the predation rate of predator, and \(c\) is the self-saturation density of prey; \(m\) represents the semi-saturation term of the system; \(\beta\) measures the conversion rate of \(v\) predating \(u\), and \(r\) reflects the protection of the surroundings on predators; \(\nu\) is the outward unit normal vector on \(\partial \Omega\). All parameters are positive constants. \(u_0(x), v_0(x)\) are both smooth functions in \(\Omega\).

For system (1), we consider the large-time behavior of positive solutions. In addition, corresponding to (1), we mainly analyze the steady-state system

\[
\begin{align*}
d_1 \Delta u + u \left( a - u - \frac{\alpha v}{c + u + mv} \right) &= 0, \quad x \in \Omega, \\
d_2 \Delta v + v \left( b - v - \frac{\beta v}{r + u} \right) &= 0, \quad x \in \Omega, \\
\frac{\partial u}{\partial \nu} &= \frac{\partial v}{\partial \nu} = 0, \quad x \in \partial \Omega.
\end{align*}
\] (2)

An outline of this paper is as follows: In Section 2, we consider the large-time behavior of positive solutions to system (1) mainly by the comparison principle of parabolic equations. In Section 3, we give a priori estimate for the positive solutions of (2) by the maximum principle. Then, in Section 4, we investigate the coexistence of predator and prey to system (2) by the energy integral techniques and topological degree computation. In Section 5, by taking the diffusion rate of predator as a parameter, we study the bifurcating phenomenon, which emits from the unique positive constant equilibrium also by using the topological degree techniques. Since pattern is a very interesting nonlinear phenomena and pattern dynamics is a primary branch of nonlinear science, finally, we give some numerical examples and depict the corresponding trajectory graphs or spatiotemporal patterns to simulate the related theoretical results in Section 6. It is worth mentioning that the numerical simulated graphs imply that the available food resource for predator may not single if the system parameters are controlled properly.
2 Large-time behavior

In this section, we consider the large-time behaviors of positive solutions to system (1) including the global attractor and the persistence.

Lemma 1. Let \( k > 0 \) be a constant. If the function \( f(x, t) \) satisfies

\[
\begin{align*}
\frac{\partial f}{\partial t} &= d \Delta f + f(k - f), \quad x \in \Omega, \quad t > 0, \\
\frac{\partial f}{\partial \nu} &= 0, \quad x \in \partial \Omega, \quad t > 0, \\
f(x, 0) &= f_0(x) \geq 0, \quad \neq 0, \quad x \in \Omega,
\end{align*}
\]

with \( \Omega \) being the same as that of in (1) and \( f_0 \) being a smooth function in \( \Omega \), then \( \lim_{t \to \infty} f(x, t) = k \) holds uniformly in \( \Omega \).

Proof. For any \( \chi_0 > 0 \), it is well known that the problem

\[
\frac{d\chi}{dt} = \chi(k - \chi), \quad \chi(0) = \chi_0
\]

has a unique solution \( \chi = \chi(t; \chi_0) \) satisfying \( \lim_{t \to \infty} \chi(t; \chi_0) = k \). Here we use the mark \( \chi(t; \chi_0) \) to represent that the solution \( \chi \) is related to \( \chi_0 \).

Let \( \tilde{M} = \max_{\Omega} f_0(x) \). Then \( \tilde{M} > 0 \) and \( f(M, t) \) is an upper-solution of (3). Obviously, 0 is a lower-solution of (3). These lead to (3) permitting a unique nonnegative solution \( f(x, t) \), and \( f(x, t) \) satisfies \( 0 \leq f(x, t) \leq f(M, t) \). Then the maximum principle induces that \( f(x, t) > 0, \quad x \in \Omega, \quad t > 0 \). Take some \( \tau > 0 \). Then \( f(x, \tau) > 0 \) for \( x \in \Omega \). Denote \( z(x, t) = f(x, t + \tau) \). Then \( z(x, t) \) satisfies

\[
\begin{align*}
\frac{\partial z}{\partial t} &= d \Delta z + z(k - z), \quad x \in \Omega, \quad t > 0, \\
\frac{\partial z}{\partial \nu} &= 0, \quad x \in \partial \Omega, \quad t > 0, \\
z(x, 0) &= f(x, \tau), \quad x \in \Omega.
\end{align*}
\]

By the comparison principle of parabolic equations, for any \( t \geq 0 \), we have

\[
f(k, t) \leq z(x, t) = f(x, t + \tau) \leq f(\overline{k}, t)
\]

with \( \underline{k} = \min_{\Omega} f(x, \tau), \overline{k} = \max_{\Omega} f(x, \tau) \). Since \( \lim_{t \to \infty} f(k, t) = \lim_{t \to \infty} f(\overline{k}, t) = k \), then \( \lim_{t \to \infty} f(x, t + \tau) = k \). Therefore, \( \lim_{t \to \infty} f(x, t) = k \) holds uniformly in \( \overline{\Omega} \).

\[ \square \]

Theorem 1. If \( (u(x, t), v(x, t)) \) is a positive solution of (1), then

\[
\lim_{t \to \infty} \sup_{\Omega} \max_{\overline{\Omega}} u(x, t) \leq a, \quad \lim_{t \to \infty} \sup_{\Omega} \max_{\overline{\Omega}} v(x, t) \leq b.
\]

Hence, for any \( \epsilon > 0 \), the rectangle \([0, a + \epsilon] \times [0, b + \epsilon]\) is a global attractor of (1).

http://www.journals.vu.lt/nonlinear-analysis
Proof. Clearly, \( u(x,t) \) satisfies

\[
\frac{\partial u}{\partial t} \leq d_1 \Delta u + u(a - u), \quad x \in \Omega, \quad t > 0,
\]

\[
\frac{\partial u}{\partial \nu} = 0, \quad x \in \partial \Omega, \quad t > 0,
\]

\[
u(x,0) = u_0(x) \geq 0, \quad \neq 0, \quad x \in \Omega.
\]

By the comparison principle of parabolic equations and Lemma 1 we know that for any \( 0 < \varepsilon \ll 1 \), there exists \( t_1 > 0 \) such that \( u(x,t) \leq a + \varepsilon, x \in \bar{\Omega} \) when \( t > t_1 \). Hence, we get

\[
l \limsup_{t \to \infty} \max_{\Omega} u(x,t) \leq a + \varepsilon.
\]

Likewise, using the comparison principle of parabolic equations and Lemma 1 again, we also know that there is \( t_2 \) with \( t_2 > t_1 \) such that \( v(x,t) \leq b + \varepsilon, x \in \bar{\Omega} \) for \( 0 < \varepsilon \ll 1 \) when \( t > t_2 \). So, \( \limsup_{t \to \infty} \max_{\Omega} v(x,t) \leq b + \varepsilon \). Then the arbitrariness of \( \varepsilon \) induces that the conclusion holds.

The result shows that any positive solution \((u(x,t), v(x,t))\) of (1) lies in a bounded region when \( t \to \infty \), that is, \((u(x,t), v(x,t))\) exists globally, and the rectangle \([0, a + \varepsilon] \times [0, b + \varepsilon]\) is a global attractor of (1) for any \( \varepsilon > 0 \).

**Theorem 2.** If \( ac > b\alpha \), then (1) is persistent. Specifically, any positive solution \((u(x,t), v(x,t))\) of (1) satisfies

\[
\liminf_{t \to \infty} \min_{\Omega} u(x,t) \geq \frac{ac - b\alpha}{c}, \quad \liminf_{t \to \infty} \min_{\Omega} v(x,t) \geq \frac{br}{r + \beta}.
\]

Proof. For any \( \varepsilon > 0 \), the proof of Theorem 1 implies that \( u(x,t) \) satisfies

\[
\frac{\partial u}{\partial t} \geq d_1 \Delta u + u \left( a - u - \frac{\alpha(b + \varepsilon)}{c} \right), \quad x \in \Omega, \quad t > t_2,
\]

\[
\frac{\partial u}{\partial \nu} = 0, \quad x \in \partial \Omega, \quad t > t_2,
\]

\[
u(x, t_2) \geq 0, \quad x \in \Omega,
\]

where \( t_2 \) is defined in the proof of Theorem 1. Similar as that we prove Theorem 1, there exists \( t_3, t_3 > t_2 \) such that \( u(x,t) \geq a - (\alpha(b + \varepsilon)) / c - \varepsilon, x \in \bar{\Omega} \) when \( t > t_3 \). Therefore,

\[
\liminf_{t \to \infty} \min_{\Omega} u(x,t) \geq a - \frac{\alpha(b + \varepsilon)}{c} - \varepsilon.
\]

Since \( u(x,t) \geq 0, x \in \bar{\Omega} \), then \( v(x,t) \) satisfies

\[
\frac{\partial v}{\partial t} \geq d_2 \Delta v + v \left( b - v - \frac{\beta}{r} v \right), \quad x \in \Omega, \quad t > 0,
\]

\[
\frac{\partial v}{\partial \nu} = 0, \quad x \in \partial \Omega, \quad t > 0,
\]

\[
v(x,0) = v_0(x) \geq 0, \quad \neq 0, \quad x \in \Omega.
\]
Hence, there is $t_4$ with $t_4 > t_3$ such that $v(x,t) \geq br/(r+\beta) - \varepsilon > 0$, $x \in \overline{\Omega}$ when $t > t_4$. So,
\[
\liminf_{t \to \infty} \min_{\overline{\Omega}} v(x,t) \geq \frac{br}{r+\beta} - \varepsilon.
\]
Then the arbitrariness of $\varepsilon$ implies that
\[
\liminf_{t \to \infty} \min_{\overline{\Omega}} u(x,t) \geq \frac{ac - b\alpha}{c} \quad \text{and} \quad \liminf_{t \to \infty} \min_{\overline{\Omega}} v(x,t) \geq \frac{br}{r+\beta}.
\]
This shows that system (1) is persistent.

**Remark 1.** Theorem 2 implies that the predator and prey always coexist in their living surroundings despite the location and time as long as $ac > b\alpha$, moreover, this coexistence is independent of their diffusion situation.

### 3 A priori estimate

In this section, we seek a priori estimate for the positive solutions of (2), which will be used frequently in the latter contents. As preparation, we introduce the following lemma due to [14].

**Lemma 2.** Suppose the functions $\omega(x) \in C^2(\Omega) \times C^1(\overline{\Omega})$ and $g(x, \omega) \in C(\Omega \times \mathbb{R})$. Then the followings hold.

(i) If $\omega(x)$ satisfies $\Delta \omega(x) + g(x, \omega(x)) \geq 0$, $x \in \Omega$, $\partial \omega/\partial \nu \leq 0$, $x \in \partial\Omega$, and $\omega(x_0) = \max_{\overline{\Omega}} \omega$, then $g(x_0, \omega(x_0)) \geq 0$.

(ii) If $\omega(x)$ satisfies $\Delta \omega(x) + g(x, \omega(x)) \leq 0$, $x \in \Omega$, $\partial \omega/\partial \nu \geq 0$, $x \in \partial\Omega$, and $\omega(x_0) = \min_{\overline{\Omega}} \omega$, then $g(x_0, \omega(x_0)) \leq 0$.

**Theorem 3.** Let $(u(x), v(x))$ be any positive solution of (2). Then
\[
\max_{\overline{\Omega}} u(x) \leq a, \quad \max_{\overline{\Omega}} v(x) \leq \frac{b(a + r)}{a + r + \beta} < b.
\]

**Proof.** Since $(u(x), v(x))$ satisfies (2), then regularity theory of elliptic equations implies that $u(x)$ and $v(x)$ must attain their maximum and minimum values in $\overline{\Omega}$. By the first equation of (2) we have
\[
\Delta u + d_1^{-1}u(a - u) \geq 0, \quad x \in \Omega; \quad \frac{\partial u}{\partial \nu} = 0, \quad x \in \partial\Omega.
\]
Then Lemma 2(i) induces $u(a - u) \geq 0$ at the maximum of $u$, so $\max_{\overline{\Omega}} u(x) \leq a$.

Then by $\max_{\overline{\Omega}} u(x) \leq a$ and the second equation of (2) we get
\[
\Delta v + d_2^{-1}v\left(b - v - \frac{\beta v}{a + r}\right) \geq 0, \quad x \in \Omega; \quad \frac{\partial v}{\partial \nu} = 0, \quad x \in \partial\Omega.
\]
Using Lemma 2(ii) again, there holds $v(b - v - \beta v/(a + r)) \geq 0$ at the maximum of $v$, and further, $\max_{\overline{\Omega}} v(x) \leq (a + r)/(a + r + \beta) < b$. The proof is finished. □

---

http://www.journals.vu.lt/nonlinear-analysis
In the following, for convenience in use, we denote \( \wedge = \wedge(a, b, c, m, r, \alpha, \beta) \).

**Theorem 4.** Let \( d > 0 \) be a given number. If \( d_1 \geq d \), then there is a constant \( C = C(d, n, \Omega, \wedge) \) such that any positive solution \( (u(x), v(x)) \) of (2) satisfies

\[
\min_{\Omega} u(x) \geq C, \quad \min_{\Omega} v(x) \geq C.
\]

**Proof.** Denote
\[
u(x_1) = \min_{\Omega} u(x), \quad \nu(x_2) = \max_{\Omega} u(x);
\]
\[
\nu(y_1) = \min_{\Omega} v(x), \quad \nu(y_2) = \max_{\Omega} v(x).
\]

Similar to the proof of Theorem 3, apply Lemma 2(ii) directly to the first equation of (2) to yield
\[
d_1^{-1}u(x_1)(a - u(x_1) + \frac{\alpha v(x_1)}{c + u(x_1) + mv(x_1)}) \leq 0,
\]
which implies \( a \leq u(x_1) + \alpha v(x_1)/(c + u(x_1) + mv(x_1)) \). Then use Lemma 2(i) and (ii) to the second equation of (2) continuously to get
\[
v(y_2) \leq \frac{b(r + u(y_2))}{r + \beta + u(y_2)} \quad \text{and} \quad v(y_1) \geq \frac{b(r + u(y_1))}{a + r + \beta},
\]
respectively. Combining with Theorem 3, we get
\[
v(y_2) \leq \frac{b(r + u(x_2))}{r + \beta} \quad \text{and} \quad v(y_1) \geq \frac{b(r + u(x_1))}{a + r + \beta}.
\]

Thus,
\[
a \leq u(x_1) + \frac{\alpha v(x_1)}{c + u(x_1) + mv(x_1)} \leq u(x_1) + \frac{b\alpha (r + u(x_2))}{c(r + \beta + u(x_2))}
\]
\[
\leq u(x_1) + Pu(x_2),
\]
where \( P > 0 \) is a constant satisfying \( P > b\alpha(r + u(x_2))/(cu(x_2)(r + \beta + u(x_2))) \). Now, let
\[
h(x) = d_1^{-1}\left(a - u - \frac{\alpha v}{c + u + mv}\right).
\]

Then \( h(x) \) and \( u \) satisfy
\[
\Delta u(x) + h(x)u(x) = 0, \quad x \in \Omega; \quad \frac{\partial u}{\partial \nu} = 0, \quad x \in \partial \Omega.
\]

Further, by the Harnack inequality when \( d_1 > d \), there is \( C_* = C_*(d, n, \Omega, \|h\|_\infty) \) such that
\[
\max_{\Omega} u(x) \leq C_* \min_{\Omega} u(x), \quad \text{i.e.} \quad u(x_2) \leq C_*u(x_1).
\]
Substitute (6) into (5) to get
\[
\min_{\Omega} u(x) = u(x_1) \geq \frac{a}{1 + PC_*}.
\]
(7)
Combining (4) with (7), we have
\[
\min_{\Omega} v(x) = v(y_1) \geq \frac{b(r + \frac{a}{1 + PC_*})}{a + r + \beta}.
\]
Take
\[
C = \min \left\{ \frac{a}{1 + PC_*}, \frac{b(r + \frac{a}{1 + PC_*})}{a + r + \beta} \right\}.
\]
The result follows.

In a same way, if we take \(d_2\) as the parameter, then we can get a very similar estimate on the lower bound.

4 Coexistence

4.1 Nonexistence

This subsection devotes to the nonexistence of nonconstant positive solutions to system (2) by energy integral procedure. The following two nonexistent results are based on the priori estimates obtained in the previous section.

Theorem 5. If \((\sqrt{(am - a - c - \alpha)^2 - 4am(a + c) + am - a - c - \alpha)}/2m < C\) or \(b(a + r)/(a + r + \beta) < C\) holds, then (2) has no nonconstant positive solution, where \(C\) is given in Theorem 4.

Proof. We only prove the result holds under the first condition since the second case can be proved similarly. Suppose that \((u, v)\) is a nonconstant positive solution to system (2). Integrating the first equation of (2) in \(\Omega\), we get
\[
0 = \int_{\Omega} u \left( a - u - \frac{\alpha v}{c + u + mv} \right) dx \leq \int_{\Omega} \left( a - C - \frac{\alpha C}{c + a + mC} \right) u dx.
\]
Using the positivity of \(u\), we obtain further \(mC^2 - (am - a - c - \alpha)C - a(a + c) \leq 0\), which induces \(C \leq (\sqrt{(am - a - c - \alpha)^2 - 4am(a + c) + am - a - c - \alpha)}/2m\), a contradiction occurs.

Theorem 6. Let \(d_2 > b\mu_1^{-1}\) with \(\mu_1\) being the second eigenvalue of \(-\Delta\) with homogenous Neumann boundary condition. Then there exists a positive constant \(\tilde{D} = \tilde{D}(\mu_1, \alpha)\) or \(\tilde{D} = \tilde{D}(\mu_1, \wedge)\) such that (2) does not permit any nonconstant positive solution if \(d_1 > \tilde{D}\).

Proof. Let \((u, v)\) be a nonconstant positive solution. Denote \(\overline{u} = (1/|\Omega|) \int_{\Omega} u(x) dx\), \(\overline{v} = (1/|\Omega|) \int_{\Omega} v(x) dx\). Multiply the first equality in (2) by \(u - \overline{u}\) and then integrate

http://www.journals.vu.lt/nonlinear-analysis
Analysis and simulation on dynamics of a partial differential system

in $\Omega$ to get

\[
\begin{align*}
&d_1 \int_{\Omega} |\nabla(u - \overline{u})|^2 \, dx \\
&= \int_{\Omega} \left( u \left( a - u - \frac{\alpha v}{c + u + m \overline{v}} \right) - \overline{u} \left( a - \overline{u} - \frac{\alpha \overline{v}}{c + \overline{u} + m \overline{v}} \right) \right) (u - \overline{u}) \, dx \\
&= \int_{\Omega} \left( (a - u - \overline{u})(u - \overline{u})^2 - \frac{\alpha u(c + \overline{u})(u - \overline{u})(v - \overline{v})}{(c + u + m \overline{v})(c + \overline{u} + m \overline{v})} \right) \, dx \\
&\quad - \int_{\Omega} \frac{\alpha \overline{v}(c + m \overline{v})(u - \overline{u})^2}{(c + u + m \overline{v})(c + \overline{u} + m \overline{v})} \, dx \\
&\leq \int_{\Omega} \left( a(u - \overline{u})^2 + \alpha |u - \overline{u}| |v - \overline{v}| \right) \, dx.
\end{align*}
\]

Similarly, we can get

\[
\begin{align*}
&d_2 \int_{\Omega} |\nabla(v - \overline{v})|^2 \, dx = \int_{\Omega} \left( v \left( b - v - \frac{\beta v}{r + u} \right) - \overline{v} \left( b - \overline{v} - \frac{\beta \overline{v}}{r + \overline{u}} \right) \right) (v - \overline{v}) \, dx \\
&\quad \leq \int_{\Omega} \left( b(v - \overline{v})^2 + \frac{\beta \overline{v}^2}{(r + u)(r + \overline{u})} |u - \overline{u}| |v - \overline{v}| \right) \, dx.
\end{align*}
\]

Add these two inequalities and use the Cauchy inequality to yield

\[
\begin{align*}
&\int_{\Omega} \left( d_1 |\nabla(u - \overline{u})|^2 + d_2 |\nabla(v - \overline{v})|^2 \right) \, dx \\
&\leq \int_{\Omega} \left( a(u - \overline{u})^2 + 2L |u - \overline{u}| |v - \overline{v}| + b(v - \overline{v})^2 \right) \, dx \\
&\leq \int_{\Omega} \left( (a + \varepsilon^{-1}L)(u - \overline{u})^2 + (b + \varepsilon L)(v - \overline{v})^2 \right) \, dx,
\end{align*}
\]

where $\varepsilon > 0$ is arbitrary and $L = \max\{\alpha, \beta \overline{v}^2/((r + C)(r + \overline{u}))\}$. Using the Poincaré equality, we have

\[
\begin{align*}
&\mu_1 \int_{\Omega} \left( d_1 |u - \overline{u}|^2 + d_2 |v - \overline{v}|^2 \right) \, dx \\
&\quad \leq \int_{\Omega} \left( d_1 |\nabla(u - \overline{u})|^2 + d_2 |\nabla(v - \overline{v})|^2 \right) \, dx \\
&\quad \leq \int_{\Omega} \left( (a + \varepsilon^{-1}L)(u - \overline{u})^2 + (b + \varepsilon L)(v - \overline{v})^2 \right) \, dx.
\end{align*}
\]
Since $d_2 > b\mu_1^{-1}$, take $\varepsilon$ small enough such that $\mu_1 d_2 > b + \varepsilon L$. Then there holds
\[
d_1 \int_{\Omega} |u - \overline{u}|^2 \, dx \leq \mu_1^{-1}(a + \varepsilon^{-1} L) \int_{\Omega} |u - \overline{u}|^2 \, dx.
\]
Denote $\tilde{D} = \mu_1^{-1}(a + \varepsilon^{-1} L)$. Then this inequality holds if and only if $u \equiv \overline{u}$ is a constant in view of $d_1 > \tilde{D}$. This is a contradiction, and the proof is complete.

\section*{4.2 Existence}

This subsection deals with the existence of nonconstant positive solutions to system (2) by choosing $d_2$ as the parameter and by using the Leray–Schauder degree theory.

Firstly, we give some preliminaries. Denote
\[
X = \left\{ (u, v)^T \in (C^2(\Omega) \cap C^1(\overline{\Omega})) \times (C^2(\Omega) \cap C^1(\overline{\Omega})): \frac{\partial u}{\partial \nu} = \frac{\partial v}{\partial \nu} = 0, \; x \in \partial \Omega \right\}.
\]
Denote by $0 = \mu_0 < \mu_1 < \mu_2 < \cdots$ the eigenvalues of $-\Delta$ under homogenous Neumann boundary condition in $\Omega$ and $E(\mu_i)$ the eigenspace corresponding to each $\mu_i$ in $C^2(\Omega) \cap C^1(\overline{\Omega})$. Let $\{ \varphi_{il}, \; l = 1, 2, \ldots, m(\mu_i) \}$ be an orthogonal basis in $E(\mu_i)$ and $X_{il} = \{ C \varphi_{il}: \; C \in \mathbb{R}^2 \}$ with $m(\mu_i)$ being the multiplicity of $\mu_i$, $i = 0, 1, 2, \ldots$. Then $X_i = \bigoplus_{l=1}^{m(\mu_i)} X_{il}$ and $X = \bigoplus_{i=0}^{\infty} X_i$.

Rewrite system (2) as
\[
-\Delta U = D^{-1} F(U), \quad x \in \Omega; \quad \frac{\partial U}{\partial \nu} = 0, \quad x \in \partial \Omega, \quad (8)
\]
with
\[
U = (u, v)^T \in X, \quad D = \text{diag}(d_1, d_2),
\]
\[
F(U) = \left( u\left(a - u - \frac{\alpha v}{c + u + mv}\right), \; v\left(b - v - \frac{\beta v}{u + r}\right) \right)^T.
\]
So, $U$ is a solution of (2) if and only if $U$ is a solution of (8), this is equivalent to
\[
G(d_1, d_2; U) := U - (I - \Delta)^{-1} [D^{-1} F(U) + U] = 0, \quad x \in \Omega,
\]
\[
\frac{\partial U}{\partial \nu} = 0, \quad x \in \partial \Omega,
\]
namely, $U$ is a zero point of $G(d_1, d_2; \cdot)$, where $(I - \Delta)^{-1}$ is the inverse of $I - \Delta$.

In the following, we need to use the positive constant solution of (2). By a direct analysis on the derivative of a cubic function it can be easily shown that (2) admits a unique positive constant solution denoted by $(u^*, v^*) =: U^*$ if one of the following two cases holds.

(H1) $br\alpha/(cr + c\beta + bmr) < a < c + r + \beta + bm$;

(H2) $a > \max\{c + r + \beta + bm, br\alpha/(cr + c\beta + bmr), (cr + c\beta + bmr + ba)/(c + r + \beta + bm)\}$.

http://www.journals.vu.lt/nonlinear-analysis
Clearly, \( U^* \) is a zero point of \( G(d_1, d_2; \cdot) \), and the Fréchet derivative of \( G(d_1, d_2; \cdot) \) on \( U \) at \( U^* \) is

\[
D_U G(d_1, d_2; U^*) = I - (I - \Delta)^{-1}(D^{-1}B + I),
\]

where \( B = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} \) with

\[
a_{11} = \frac{u^*(2u^* + mv^* - a + c)}{c + u^* + mv^*}, \quad a_{12} = -\frac{\alpha u^*(c + u^*)}{(c + u^* + mv^*)^2}, \quad a_{21} = \frac{(b - v^*)^2}{\beta}, \quad a_{22} = -b.
\]

It is easy to check that \( \lambda \) is an eigenvalue of \( D_U G(d_1, d_2; U^*) \) on \( X_i \) if and only if \( \lambda(1 + \mu_i) \) is an eigenvalue of the matrix

\[
\mu_i I - D^{-1}B = \begin{pmatrix} \mu_i - a_{11}d_1^{-1} & -a_{12}d_1^{-1} \\ -a_{21}d_2^{-1} & \mu_i - b_d^{-1} \end{pmatrix} =: M_i.
\]

Thus, \( D_U G(d_1, d_2; U^*) \) is invertible if and only if \( M_i \) is nonsingular. By decomposition \( X_i = \oplus_{\nu=1}^{m(\mu_i)} X_{i\nu} \) it is seen that \( \lambda \) is an eigenvalue of \( D_U G(d_1, d_2; U^*) \) on each \( X_{i\nu} \), also, the multiplicity of \( \lambda \) is equivalent to the multiplicity of the eigenvalues \( \lambda(1 + \mu_i) \) of \( M_i \). Therefore, if \( \lambda \) is an \( q \)-multiplicity eigenvalue of \( D_U G(d_1, d_2; U^*) \) on each \( X_i \) and \( \lambda(1 + \mu_i) \) is an \( n \)-multiplicity eigenvalue of \( M_i \), then \( q = nm(\mu_i) \).

Direct computation yields

\[
\det M_i = \frac{d_1d_2\mu_i^2 - (bd_1 + a_{11}d_2)\mu_i + a_{11}b - a_{12}a_{21}}{d_1d_2},
\]

\[
\tr M_i = 2\mu_i - a_{11}d_1^{-1} - b_d^{-1}.
\]

Denote

\[
\mathcal{H}(d_1, d_2; \theta) = d_1d_2\theta^2 - (bd_1 + a_{11}d_2)\theta + a_{11}b - a_{12}a_{21}.
\]

In the following, if it involves \( \mathcal{H}(d_1, d_2; \theta) \) but does not emphasize the effects of \( d_1 \) and \( d_2 \) on \( \mathcal{H} \), we use \( h(\theta) \) to denote \( \mathcal{H}(d_1, d_2; \theta) \) for simplicity. Then \( h(\mu_i) = d_1d_2 \det M_i. \) If

\[
(bd_1 + a_{11}d_2)^2 > 4d_1d_2(a_{11}b - a_{12}a_{21}),
\]

then \( h(\theta) = 0 \) has two real roots denoted by \( \theta_1 = \theta_1(d_1, d_2), \theta_2 = \theta_2(d_1, d_2) \), respectively, and

\[
\theta_1 = \frac{bd_1 + a_{11}d_2 + \sqrt{(bd_1 + a_{11}d_2)^2 - 4d_1d_2(a_{11}b - a_{12}a_{21})}}{2d_1d_2},
\]

\[
\theta_2 = \frac{bd_1 + a_{11}d_2 - \sqrt{(bd_1 + a_{11}d_2)^2 - 4d_1d_2(a_{11}b - a_{12}a_{21})}}{2d_1d_2}.
\]

Denote by \( \mathcal{S} \) the set of all eigenvalues of \( -\Delta \) under homogenous Neumann boundary condition in \( \Omega \). Let \( \mathcal{T} = \mathcal{T}(d_1, d_2) = \{\theta: \theta \geq 0, \theta_2(d_1, d_2) < \theta < \theta_1(d_1, d_2)\} \) with \( \theta_1, \theta_2 \) being given by (11). Then we have the following lemma.
Lemma 3. If $h(\mu_i) \neq 0$ for $\mu_i \in S$, then the index equality $\text{index}(G(d_1, d_2; \cdot), U^*) = (-1)^\sigma$ holds, where

$$\sigma = \begin{cases} \sum_{\mu_i \in T \cap S} m(\mu_i), & T \cap S \neq \emptyset, \\ 0, & T \cap S = \emptyset. \end{cases}$$

Proof. Since $h(\mu_i) \neq 0$, we know $\det M_i \neq 0$. So the matrix $M_i$ is nonsingular, and $D_U G(d_1, d_2; U^*)$ is invertible. Then $\text{index}(G(d_1, d_2; \cdot), U^*) = (-1)^\gamma$ holds with $\gamma = \sum_{i \geq 0} \sum_{\text{Re } \lambda_i < 0} m(\lambda_i)$ and $\lambda_i$ being an eigenvalue of $D_U G(d_1, d_2; U^*)$ on $X_i$.

Now, we need to show $\gamma = \sigma$. Denote by $\tau_i$ the eigenvalue of $M_i$. Then $\tau_i = \lambda_i(1 + \mu_i)$, $m(\lambda_i) = m(\tau_i)m(\mu_i)$. The sum of algebraic multiplicity of the eigenvalues with negative real parts of $M_i$ modulo 2 can be expressed as

$$\frac{1}{2} \left(1 - \text{sgn}(\det M_i)\right) = \frac{1}{2} \left(1 - \text{sgn}(h(\mu_i))\right) =: \rho_i,$$

where

$$\text{sgn}(\det M_i) = \begin{cases} 1, & \det M_i > 0, \\ -1, & \det M_i < 0. \end{cases}$$

For each $\mu_i \in S$, if $\mu_i \in T$, then $\det M_i < 0$. By (12) we have $\rho_i = 1$. If $\mu_i \notin T$, then $\det M_i > 0$. By (12), again, we get $\rho_i = 0$. Therefore,

$$\sum_{i \geq 0} \rho_i m(\mu_i) = \sum_{\mu_i \in T \cap S} m(\mu_i),$$

Further, $\gamma = \sum_{i \geq 0} \sum_{\text{Re } \tau_i < 0} m(\tau_i)m(\mu_i) = \sum_{i \geq 0} \rho_i m(\mu_i) = \sigma$. 

\[\square\]

Theorem 7. Suppose $a_{11} > 0$. If there is $n \geq 1$ such that $a_{11}d_1^{-1} \in (\mu_n, \mu_{n+1})$ and $\sigma_n = \sum_{i=1}^n m(\mu_i)$ is odd, then there exists $d^* > 0$ such that (2) has at least a nonconstant positive solution when $d_2 > d^*$.

Proof. Since $a_{11} > 0$, it is easy to see that (10) holds if $d_2$ large enough, moreover, $\theta_1 > \theta_2 > 0$ and $\lim_{d_2 \to +\infty} \theta_1 = a_{11}d_1^{-1}$, $\lim_{d_2 \to +\infty} \theta_2 = 0$. Furthermore, since $a_{11}d_1^{-1} \in (\mu_n, \mu_{n+1})$, there is large $d_0$ such that

$$\theta_1 \in (\mu_n, \mu_{n+1}), \quad 0 < \theta_2 < \mu_1$$

holds if $d_2 \geq d_0$. By Theorem 5 there exists $d \geq d_0$ such that (2) has no nonconstant positive solution for $d_1 = d$, $d_2 \geq d$. Take $d$ large enough such that $0 < a_{11}d_1^{-1} < \mu_1$. Then there is $d^* > d$ such that the following holds for $d_2 \geq d^*$:

$$0 < \theta_2(d, d_2) < \theta_1(d, d_2) < \mu_1.$$

Now, we show that (2) has at least a nonconstant positive solution when $d_2 \geq d^*$. We prove this by contradiction. Suppose that there exists $d^*_2 \geq d^*$ such that (2) has no nonconstant positive solution. Fix $d_2 = d^*_2$ and define the homotopy operator $W(t)$ as

$$W(t) = \begin{pmatrix} td_1 + (1-t)d & 0 \\ 0 & td_2 + (1-t)d^* \end{pmatrix}, \quad t \in [0, 1].$$
Denote $U = (u(x), v(x))$. Consider the problem

$$-\Delta U = \mathcal{W}^{-1}(t)F(U), \quad x \in \Omega; \quad \frac{\partial U}{\partial \nu} = 0, \quad x \in \partial \Omega. \quad (15)$$

Obviously, $U$ is a solution of (2) if and only if $U$ is a solution of (15) for $t = 1$. Especially, for any $t \in [0, 1]$, $U^*$ is the unique positive constant solution of (15).

For $t \in [0, 1]$, $U$ is a positive solution of (15) if and only if the equality

$$\mathcal{K}(U; t) := U - (I - \Delta)^{-1}[\mathcal{W}^{-1}(t)F(U) + U] = 0 \quad (16)$$

holds. By the discussion above we know that (16) has no nonconstant positive solution for $t = 0$. By our assumption (16) has no nonconstant positive solution for $d_2 = d^*$ and $t = 1$, furthermore, the followings equalities hold:

$$\mathcal{K}(U; 1) = G(d_1, d_2; U), \quad \mathcal{K}(U; 0) = G(d, d^*; U),$$

$$D_u G(d_1, d_2; U^*) = I - (I - \Delta)^{-1}(\mathcal{W}^{-1}B + I),$$

$$D_u G(d, d^*; U^*) = I - (I - \Delta)^{-1}(\tilde{\mathcal{W}}^{-1}B + I),$$

where $\tilde{\mathcal{W}} = \text{diag}(d, d^*)$. Then (13) and (14) induce that

$$\mathcal{T}(d_1, d_2) \cap S = \{\mu_1, \mu_2, \ldots, \mu_n\}, \quad \mathcal{T}(d, d^*) \cap S = \emptyset.$$ 

Since $\sigma_n$ is odd, Lemma 3 implies that

$$\text{index}(\mathcal{K}(\cdot; 1), U^*) = \text{index}(G(d_1, d_2; \cdot), U^*) = (-1)^{\sigma_n} = -1,$$

$$\text{index}(\mathcal{K}(\cdot; 0), U^*) = \text{index}(G(d, d^*; \cdot), U^*) = (-1)^0 = 1.$$ 

Thanks to Theorems 3 and 4, we know that there exist positive constants $P_1$, $P_2$ with $P_1 < \underline{C}$ and $P_2 > \max\{a, b(a + r)/(a + r + \beta)\}$ such that any positive solution $(u(x), v(x))$ of (15) satisfies $P_1 < u(x), v(x) < P_2$, $x \in \overline{\Omega}$ for $t \in [0, 1]$. Define

$$\Theta = \{U \in X: P_1 < u(x), v(x) < P_2, \quad U = (u(x), v(x))^T\}.\quad \text{Then, clearly, } \mathcal{K}(U; t) \neq 0 \quad \text{for } t \in [0, 1] \text{ if } U \in \partial \Theta. \quad \text{By the homotopy invariance of degree we get}$$

$$\deg(\mathcal{K}(\cdot; 0), \Theta, 0) = \deg(\mathcal{K}(\cdot; 1), \Theta, 0). \quad (17)$$

However, the equations $\mathcal{K}(U; 0) = 0$ and $\mathcal{K}(U; 1) = 0$ both have a unique positive solution $U^*$ in $\Theta$, therefore,

$$\deg(\mathcal{K}(\cdot; 0), \Theta, 0) = \text{index}(\mathcal{K}(\cdot; 0), U^*) = 1,$$

$$\deg(\mathcal{K}(\cdot; 1), \Theta, 0) = \text{index}(\mathcal{K}(\cdot; 1), U^*) = -1.$$ 

These contradict to (17), and the proof is completed.
5 Bifurcation

In this section, taking $d_2$ as a parameter, we investigate the existence of bifurcation solutions emitting from $U^*$ by using the topological degree techniques.

For some $\tilde{d}_2 \in (0, +\infty)$, if $(\tilde{d}_2; U^*)$ satisfies: for any $\delta \in (0, \tilde{d}_2)$, there is $d_2 \in [\tilde{d}_2 - \delta, \tilde{d}_2 + \delta]$ such that system (2) admits a nonconstant positive solution, then $(\tilde{d}_2; U^*) \in (0, +\infty) \times X$ is called a bifurcation point of (2). Otherwise, $(\tilde{d}_2; U^*)$ is called a regular point of (2).

Define $\mathcal{N}(d_2) = \{ \theta > 0: h(\theta) = 0 \}$, where $h(\theta)$ is $\mathcal{H}(d_1, d_2; \theta)$ defined by (9). Obviously, $\mathcal{N}(d_2)$ has at most two elements for any given $d_1, d_2 > 0$.

For some given $\tilde{d}_2 > 0$, the following holds.

**Theorem 8.**

(i) If $\mathcal{S} \cap \mathcal{N}(\tilde{d}_2) = \emptyset$, then $(\tilde{d}_2; U^*)$ is a regular point of (2).

(ii) Suppose $\mathcal{S} \cap \mathcal{N}(\tilde{d}_2) \neq \emptyset$ and $(bd_1 + a_{11}^2)^2 = 4d_1\tilde{d}_2(a_{11}b - a_{12}a_{21})$. If $\sum_{\mu_i \in \mathcal{E}(\tilde{d}_2)} m(\mu_i)$ is odd, then $(\tilde{d}_2; U^*)$ is a bifurcation point of (2).

**Proof.** Let $W(x) = U(x) - U^*$. Then (8) is equivalent to

$$-\Delta W = D^{-1}F(W + U^*), \quad x \in \Omega; \quad \frac{\partial W}{\partial \nu} = 0, \quad x \in \partial \Omega,$$

and then it is equivalent to $W$ satisfying

$$\mathcal{R}(d_2; W) := W - (I - \Delta)^{-1}[D^{-1}F(W + U^*) + W] = 0, \quad x \in \Omega,$$

$$\frac{\partial W}{\partial \nu} = 0, \quad x \in \partial \Omega.$$

The Fréchet derivative of $\mathcal{R}(d_2; \cdot)$ on $W$ at $W = 0$ is

$$D_W \mathcal{R}(d_2; 0) = I - (I - \Delta)^{-1}(D^{-1}B + I) = D_W \mathcal{G}(d_1, d_2; U^*),$$

where $B$ is given in Section 4.2. As what we do in Section 4, $\lambda$ is an eigenvalue of $D_W \mathcal{R}(d_2; 0)$ on $\mathcal{X}$ if and only if $\lambda(1 + \mu_i)$ is an eigenvalue of $M_i$.

(i) If $\mathcal{S} \cap \mathcal{N}(\tilde{d}_2) = \emptyset$, that is, $\mu_i \in \mathcal{S}$, $\mathcal{H}(d_1, \tilde{d}_2; \mu_i) \neq 0$, then $\det M_i \neq 0$, and $M_i$ is nonsingular, so $D_W \mathcal{R}(d_2; 0)$ is regular. By the implicit function theorem we know that there exists $\varepsilon, 0 < \varepsilon \ll 1$, such that $W = 0$ is the unique solution of $\mathcal{R}(d_2; \cdot) = 0$ in $\mathcal{E} = \{ W \in \mathcal{X}: \| W \|_{\mathcal{X}} < \varepsilon \}$ for any $d_2$ ($d_2$ is in a neighborhood $\tilde{d}_2$), this means that $(\tilde{d}_2; U^*)$ is a regular point of (2).

(ii) By assumptions we take $\mu_i \in \mathcal{S} \cap \mathcal{N}(\tilde{d}_2)$, then $\mathcal{H}(d_1, \tilde{d}_2; \mu_i) = 0$ and $\mu_i \neq (a_{11}d_1^{-1} + bd_2^{-1})/2$. Further,

$$\det M_i = \frac{\mathcal{H}(d_1, \tilde{d}_2; \mu_i)}{(d_1 \tilde{d}_2)} = 0, \quad \text{tr } M_i = 2\mu_i - a_{11}d_1^{-1} - bd_2^{-1} \neq 0.$$

Thus, the two eigenvalues of $M_i$ are $0$ and $\text{tr } M_i$, respectively, and $0$ is simple.

If the result is false, then there is $\tilde{d}_2 > 0$ satisfying the following.
(a) $S \cap \mathcal{N}(\tilde{d}_2) \neq \emptyset$, $(bd_1 + a_{11}\tilde{d}_2)^2 \neq 4d_1\tilde{d}_2(a_{11}b - a_{12}a_{21})$ and $\sum_{\mu_i \in \mathcal{N}(\tilde{d}_2)} m(\mu_i)$ is odd;
(b) There exists $\delta \in (0, \tilde{d}_2)$ such that $W = 0$ is the unique solution of $\mathcal{R}(d_2; \cdot) = 0$ in $\Xi$ for $d_2 \in [\tilde{d}_2 - \delta, \tilde{d}_2 + \delta]$.

Now, it needs to deduce a contradiction. Since $\mathcal{R}(d_2; \cdot)$ is a compact perturbation of $I$, then (b) implies that the Leray–Schauder degree $\deg(\mathcal{R}(d_2; \cdot), \Xi, 0)$ is well defined, furthermore, $\deg(\mathcal{R}(d_2; \cdot), \Xi, 0)$ is independent of $d_2 \in [\tilde{d}_2 - \delta, \tilde{d}_2 + \delta]$. If $D_W \mathcal{R}(d_2; 0)$ is invertible for $d_2 \in [\tilde{d}_2 - \delta, \tilde{d}_2 + \delta]$, then

$$\deg(\mathcal{R}(d_2; \cdot), \Xi, 0) = (-1)^{\gamma(d_2)},$$

(18)

where $\gamma(d_2)$ is the sum of algebraic multiplicity of the eigenvalues with negative real parts of $D_W \mathcal{R}(d_2; 0)$. For any $\mu_i \in S \cap \mathcal{N}(\tilde{d}_2)$, we have

$$\mathcal{H}(d_1, \tilde{d}_2; \mu_i) = d_1\tilde{d}_2^2 - (bd_1 + a_{11}\tilde{d}_2)\mu_i + a_{11}b - a_{12}a_{21} = 0.$$ (19)

The Fréchet derivative of $\mathcal{H}(d_1, d_2; \mu_i)$ on $d_2$ at $d_2$ is $\mathcal{H}_{d_2}(d_1, \tilde{d}_2; \mu_i) = d_1\mu_i^2 - a_{11}\mu_i$. It is easy to see that $\mathcal{H}_{d_2}(d_1, \tilde{d}_2; \mu_i) \neq 0$. (Otherwise, if $\mathcal{H}_{d_2}(d_1, \tilde{d}_2; \mu_i) = 0$, then $\mu_i = a_{11}d_1^{-1}$. Substituting $\mu_i = a_{11}d_1^{-1}$ into (19), we get $a_{12}a_{21} = 0$, which contradicts to $a_{12}a_{21} < 0$.) Therefore, for all $d_2 \in [\tilde{d}_2 - \delta, \tilde{d}_2 + \delta]$, we have

$$\mathcal{H}_{d_2}(d_1, d_2; \mu_i) \neq 0.$$ (20)

Combine (20) with (19) to get

$$\mathcal{H}(d_1, \tilde{d}_2 - \delta; \mu_i)\mathcal{H}(d_1, \tilde{d}_2 + \delta; \mu_i) < 0.$$ (21)

Clearly, $S$ has no accumulation point. So, $S \cap \mathcal{N}(d_2) = \emptyset$ for $d_2 \in [\tilde{d}_2 - \delta, \tilde{d}_2) \cup (\tilde{d}_2, \tilde{d}_2 + \delta]$ and small $\delta$. Then by the proof of (i) we know that $D_W \mathcal{R}(d_2; 0)$ is invertible when $d_2 \in [\tilde{d}_2 - \delta, \tilde{d}_2) \cup (\tilde{d}_2, \tilde{d}_2 + \delta]$.

The proof of Lemma 3 tells us that the sum of algebraic multiplicity of eigenvalues with negative real parts of $D_W \mathcal{R}(d_2; 0)$ is $\sum_{\Re \lambda_i < 0} m(\lambda_i) =: \gamma_i(d_2)$, then

$$\gamma_i(d_2) = \sum_{\Re \lambda_i < 0} m(\lambda_i) = \sum_{\Re \tau_i < 0} m(\tau_i)m(\mu_i) = \rho_i m(\mu_i),$$ (22)

where $\rho_i$ is defined by (12).

If $\mu_i \notin \mathcal{N}(\tilde{d}_2)$, then $\gamma_i(d_2)$ is independent of $d_2 \in [\tilde{d}_2 - \delta, \tilde{d}_2 + \delta]$ since $\deg(\mathcal{R}(d_2; \cdot), \Xi, 0)$ is independent of $d_2$. If $\mu_i \in \mathcal{N}(\tilde{d}_2)$, then (21) and (22) imply that the sum of algebraic multiplicity of the eigenvalues with negative real parts of $D_W \mathcal{R}(d_2 - \delta; 0)$ and $D_W \mathcal{R}(\tilde{d}_2 + \delta; 0)$ on $X_i$ satisfies

$$\gamma_i(\tilde{d}_2 - \delta) - \gamma_i(\tilde{d}_2 + \delta) = m(\mu_i) \quad \text{or} \quad \gamma_i(\tilde{d}_2 + \delta) - \gamma_i(\tilde{d}_2 - \delta) = m(\mu_i).$$

Hence,

$$\gamma(\tilde{d}_2 - \delta) - \gamma(\tilde{d}_2 + \delta) \neq \sum_{\mu_i \in \mathcal{N}(\tilde{d}_2)} m(\mu_i) \quad \text{or} \quad \gamma(\tilde{d}_2 + \delta) - \gamma(\tilde{d}_2 - \delta) = \sum_{\mu_i \in \mathcal{N}(\tilde{d}_2)} m(\mu_i).$$

Nonlinear Anal. Model. Control, 26(2):293–314
Since \( \sum \mu_i \in N(d_2) \) is odd, by (18) we get
\[
\deg(\mathcal{R}(d_2 - \delta; \cdot), \Xi, 0) \neq \deg(\mathcal{R}(d_2 + \delta; \cdot), \Xi, 0).
\]
(23)

However, \( \deg(\mathcal{R}(d_2; \cdot), \Xi, 0) \) is independent of \( d_2 \in [d_2 - \delta, d_2 + \delta] \), so (23) cannot hold. Therefore, \( (d_2; U^*) \) is a bifurcation point of (2). The proof is accomplished.

6 Numerical examples, discussions and conclusions

In the previous sections, we investigate the coexistence of prey and predator and find out their coexistent conditions. Nevertheless, from the realistic point of view, we do hope the prey and predator can coexist since our aim is to maintain the balance of ecosystems. The conditions in Theorems 7 and 8 ensure that the prey and predator can coexist and, in this case, the ecological balance may be sustainable. To clarify this point, in this section, we give some numerical examples to support our theoretical analysis. We fix \( a, b, c, m, r \) and take \( \alpha, \beta \) as parameters. For the sake of simple calculation, the parameters \( a, b, c, m \) and \( r \) are referred to [18] in part and taken as follows: \( a = 1.2, b = 0.08, c = 2.4, m = 50, r = 12 \). The parameters \( \alpha, \beta \) are chosen, and the values \( (u^*, v^*), ac, ba, b\alpha, (er + c\beta + bm) =: s_1, c + r + \beta + bm =: s_2, a_{11} \) are calculated and listed in Table 1.

Summarizing these numerical simulations, the following results follow: In Examples 1–5 with \( d_1 = 0.1, d_2 = 1 \) holds and \( (u^*, v^*) \) is worked out in each example, and then (2) may have a nonconstant positive solution according to Theorem 7.

Based on the parameter values taken above, we depict some trajectory graphs or spatiotemporal pattern formation to simulate our theoretical results.

The followings Figs. 1–5 and Figs. 6–10 are, respectively, the trajectory graphs and the spatiotemporal patterns corresponding to Examples 1–5 with \( d_1 = 0.1, d_2 = 1 \) and different initial values.

| Table 1. Simulating parameter values. |
|---------------------------------------|
| \( \alpha \) | \( \beta \) | \( (u^*, v^*) \) | \( ac \) | \( ba \) | \( s_1 \) | \( s_2 \) | \( a_{11} \) |
| Example 1 | 20 | 4 | (2.85, 0.0605) | 2.88 | 1.6 | 0.2222 | 22.4 | 3.8724 |
| Example 2 | 30 | 4 | (3.26, 0.063) | 2.88 | 2.4 | 0.3333 | 22.4 | 4.3923 |
| Example 3 | 50 | 8 | (4.24, 0.067) | 2.88 | 4.0 | 0.5 | 26.4 | 5.53 |
| Example 4 | 80 | 12 | (5.46, 0.072) | 2.88 | 6.4 | 0.7273 | 30.4 | 7.4896 |
| Example 5 | 100 | 18 | (6.22, 0.08) | 2.88 | 8.0 | 0.8 | 36.4 | 8.6942 |

Figure 1. The trajectory graphs of $u$ and $v$ of system (1) with $\alpha = 20$, $\beta = 4$ and initial data $u_0 = 0.8 + 0.02456 \cos(5x)$, $v_0 = 0.45 + 0.05132 \sin(3x)$.

Figure 2. The trajectory graphs of $u$ and $v$ of system (1) with $\alpha = 30$, $\beta = 4$ and initial data $u_0 = 0.85 + 0.02456 \cos(5x)$, $v_0 = 0.26 + 0.5132 \sin(3x)$.

Figure 3. The trajectory graphs of $u$ and $v$ of system (1) with $\alpha = 50$, $\beta = 8$ and initial data $u_0 = 0.75 + 0.02456 \cos(5x)$, $v_0 = 0.4 + 0.05132 \sin(3x)$.
Figure 4. The trajectory graphs of $u$ and $v$ of system (1) with $\alpha = 80$, $\beta = 12$ and initial data $u_0 = 0.45 + 0.02456 \cos(5x)$, $v_0 = 0.45 + 0.05132 \sin(3x)$.

Figure 5. The trajectory graphs of $u$ and $v$ of system (1) with $\alpha = 100$, $\beta = 18$ and initial data $u_0 = 0.42 + 0.02456 \cos(5x)$, $v_0 = 0.4 + 0.05132 \sin(3x)$.

All the trajectory graphs show that the quantity of prey and predator decrease and increase gradually as the predation rate of predator, the conversion rate of predator due to capturing prey increasing and time going on, and tend to stabilize eventually. Specifically, the quantity of prey and predator are as followings in turn: $0.08, 0.07, 0.06, 0.05, 0.04$ and $0.22, 0.41, 0.65, 0.84, 0.98$, respectively, from Figs. 1–5. We also see that the declining and ascending scales between the prey and predator are inconformity, in contrast, the increase of the predator is much stronger than the decrease of the prey. Though the quantity of the prey is decreasing, it is clear that such changes are very small, that is, the quantity of the prey remains roughly stable regardless some fluctuations of the predation rate and the conversion rate of predator. This situation probably implies that the available food resource for predator is not single, that is, what we want to see in population dynamics since which sustains the persistence of the species when the food resource for predator is scarce. This helps to maintain the ecological balance. Figures 6–10 show that the spatiotemporal patterns always occur for our given parameter values, which imply that the system exhibits rich dynamical behavior.
Figure 6. The spatiotemporal pattern formations of $u$ and $v$ of system (1) with $\alpha = 20$, $\beta = 4$ and initial data $u_0 = 0.8 + 0.02456 \cos(5x)$, $v_0 = 0.45 + 0.05132 \sin(3x)$.

Figure 7. The spatiotemporal pattern formations of $u$ and $v$ of system (1) with $\alpha = 30$, $\beta = 4$ and initial data $u_0 = 0.8 + 0.02456 \cos(5x)$, $v_0 = 0.26 + 0.05132 \sin(3x)$.

Figure 8. The spatiotemporal pattern formations of $u$ and $v$ of system (1) with $\alpha = 50$, $\beta = 8$ and initial data $u_0 = 0.75 + 0.02456 \cos x + 0.05132 \sin y$, $v_0 = 0.4 + 0.02456 \cos x + 0.05132 \sin y$.

In fact, we made a lot of numerical examples and trajectory graphs, we found that the differences among these simulation and graphic results are very small. Here, we only...
Figure 9. The spatiotemporal pattern formations of $u$ and $v$ of system (1) with $\alpha = 80$, $\beta = 12$ and initial data $u_0 = 0.45 + 0.04675 \cos(3x) + 0.05869 \sin(3y)$, $v_0 = 0.45 + 0.03675 \cos(3x) + 0.055521 \sin(3y)$.

Figure 10. The spatiotemporal pattern formations of $u$ and $v$ of system (1) with $\alpha = 100$, $\beta = 18$ and initial data $u_0 = 0.42 + 0.06475 \cos(3x) + 0.05268 \sin(8y)$, $v_0 = 0.4 + 0.03675 \cos(8x) + 0.05521 \sin(3y)$.

Present the above five numerical examples and their corresponding trajectory graphs, the spatiotemporal pattern formation to state our findings.

The numerical examples tell us that the ecosystem reflected by model (1) or (2) is easy to maintain stability when the predation rate and the conversion rate of predator do not change dramatically. This might imply that neither the prey nor the predator will disappear within a certain period of time, which could also mean that other species is difficult to invade such system, this is exactly what we hope to happen biologically.
