Abstract. The new SAI MSU observatory 2.5-meter telescope and capabilities of its current instrumentation are described. The facility operates actively since 2014 in parallel to the engineering works. It has delivered a number of prominent results in the field of optical and near-infrared photometry and spectroscopy as well as newly developed observational techniques like differential speckle polarimetry.

Keywords: optical and IR astronomy, astronomical instrumentation, spectroscopy, photometry, polarimetry

1 CMO SAI MSU: fact sheet

The Caucasian Mountain Observatory of Sternberg Astronomical Institute (CMO SAI MSU) was constructed in 2011-2013. It is located at an altitude of 2100 m asl at the Shadjatmaz plateau 20 km south to the city of Kislovodsk at Northern Caucasus (coordinates: 43°44’10”N, 42°40’03”E). The astroclimatic conditions of the site are reported in Kornilov et al. (2014). The observatory instrumentation includes a 2.5-m Ritchey-Chretien alt-azimuth reflector, a 60-cm robotic RC600 reflector, and an astro-climate monitor. The first light from the 2.5-meter telescope was received on November 11, 2014. Since then it has been operating interchangeably in the test (engineer) and scientific observation mode. The RC600 telescope is continuously operating in the remote mode since May 2019.
2 2.5-m telescope of CMO SAI MSU

The main instrument of CMO SAI is a 2.5-meter Ritchey-Chretien reflector built for scientific and educational works to be performed by the University staff, students and postdocs. It was designed and built by a consortium headed by Safran REOSC (France; general design and optics manufacturing), NIAOT (Nanjing Institute of Astronomical Optics and Technology, China; the mount), Gambato SAS (Italy, the dome) and SAI–Servotechnica LLC partnership (the new control system), with the overall provision of the project run by the Maveg Industriearustungen, GmbH (Germany).

The SAI2.5 is a universal multiport (Cassegrain, 2 Nasmyths plus 2 “student” Nasmyth ports) alt-az F/8 telescope having 40,000 sq.cm clear aperture and equipped with three main port rotators and two off-axis CCD autoguiders. It possesses the classic (rigid) zero-expansion substrate optics capable of delivering the images with 80% of encircled energy within \( r = 0'3 \); the actual atmosphere-impacted image quality happens to be as good as \( FWHM = 0'5 \) at the Cassegrain focus. The uncorrected field of view (10') may be expanded up to 40' using a three-lens silica Wynn corrector.

The telescope is operating at slew rates 3°/s and blind points with a precision of around 2° RMS. Tracking precision of 0.1" RMS is maintained up to the wind speeds 10 m/s. The control hardware is based on the Etel direct drives and Kollmorgen BLDC motors driven by the DeltaTau PMAC2 motion controller (main axes); the auxiliary units (mirrors, guider arms etc) control system consists of distributed Nanotec drives.

The 2.5-m telescope is operating by a software developed at SAI. Its component units (main axes and auxiliary units of the mount, the dome, its climate-control and weather station; the telescope interface for scientific equipment and the databases for observation results metadata and programs and targets) are operated via the EPICS bus by two chief program: the Observations control software and the Object planner. This structure enables the flexible scheduling of instruments, objects and programs depending on the current weather and seeing conditions continuously provided by the Astroclimatic monitor (ASM, Kornilov et al.[2010]).

The telescope is currently equipped with the following full-time instrumentation:

- **ASTRONIRCAM** – imaging IR low-res spectrometer (Nasmyth-1, since 2015)
- **NBI** – the Niels Bohr institute wide field CCD imager (Cass-1, 2014)
- **TDS** – Transient double-beam optical low-resolution spectrograph (Cass-2, 2019)
- **Speckle Polarimeter** – high angular resolution multi-mode instrument (Nasmyth-2, 2015)
2.1 NBI camera

The Wide Field Imager (NBI 4Kx4K camera) is based on two EEV CCD4482 detectors operating at $-120^\circ C$ with an LN2 cryostat and works with the Filter & Shutter Unit hosting a wide set of filters for the 10x10' field of view: $UBVRI$ Bessel set, SDSS set and narrow-band $H\alpha$, $H\beta$, $[OIII]$ & $[SII]$ filters with continua. This is a first light instrument of SAI2.5 \cite{Antipin2015} built by NBI, Copenhagen University.

As a simple and efficient CCD imager, it reaches the sky background level objects ($g',r'=21.8 m$) with a 300 s integration having signal to noise SNR=20.

2.2 ASTRONIRCAM

The Astronomical Near-Infrared Camera-spectrograph is a cryogenic (T=77K) focal reducer based on the Hawaii-2RG 2Kx2K detector built by the Mauna Kea Infrared LLC. It operates in the photometry and the low resolving power (R=1200) spectroscopy modes (see \cite{Nadjip2017} for a detailed description).

The filter set includes the MKO system $J$, $H$, $K$ and $K_s$ wide-band filters and narrow-band filters for the $CO$, $H2$, $[FeII]$ and $Br\gamma$ lines. The objects of $J > 8 m$ magnitude (saturation limit set by the minimal exposure time 1.8 s) may be measured in the 4'6 x 4'6 field in the photometric mode. An accurate account of various error sources is performed via the dithered mode of telescope acquisition and may reach the $J = 20 m$, $K = 18 m$ sources with a 10% precision in 1000 s integration.

The long-slit ($Y$, $J$, $H$, $K$) and cross-dispersed ($YJ$ and $HK$; 10'' slit) spectroscopy modes are available for objects brighter than 15'' \cite{Zheltoukhov2020}. The efficiency of these modes is low (6–14% and 1–2%) so it is planned replace the non-efficient grisms installed up to now.

2.3 TDS

The Transient Double-beam Spectrograph is a new SAI2.5 instrument built for the high-throughput low-resolution optical spectroscopy of non-stationary and extragalactic sources. Installed at the side Cassegrain port, it is aimed to serve as an always-ready tool for observations of non-stationary objects and transients.

The TDS works with 1'' and 10'' wide, 3' long slits and consists of two arms with the VPH-gratings delivering 560–740 nm (R=2500) and 350–580 nm (R=1250) spectral domains to a couple of Andor Newton DU940P cameras; the light is split between the channels with a dichroic plate. The doubled resolution is also available in the 450–560 nm range. The high transparency of the optics
and dispersers results in an overall (slitless) efficiency of 30–45% in the blue–red beams, respectively, which enables spectra of $g' = 20m$ to be recorded in 30 min with SNR=5 (Dodin et al. 2020b). The TDS control and data reduction software is developed in Python.

2.4 Speckle polarimeter

The polarimetry and high angular resolution tasks are tackled with the Speckle polarimeter (SPP, Safonov et al. 2019a) built at SAI in 2015. It is a double-beam Wollaston prism polarimeter with a rotating half-wave plate equipped with an EMCCD camera Andor iXon 897. By imaging a narrow 5x10′′ sky patch simultaneously in two linear polarizations with the sub-diffraction resolution and high frame rate, it is capable of working in the following modes: total flux polarimetry, speckle interferometry, differential speckle polarimetry and fast photometry or lucky imaging.

The instrument operates through standard Bessel $BVRI$ or middle-band $\lambda \lambda$ 550, 625 & 880 nm filters and has an Atmospheric Dispersion Corrector.

3 60-cm robotic RC600 telescope

This D=600 F=4200 mm Ritchey-Chretien telescope (ASA Astrosysteme GmbH, Austria) was intended as a photometric ground-base support of space projects as well as SAI2.5 programs, a remotely controlled or robotic photometric facility for monitoring of various non-stationary objects and exoplanet transits. It started operating in May 2019 delivering a lot of observations of various SNs, CVs, Cepheids, AGNs, microquasars and exoplanets during the very first year.

The modern direct-drive DDM160 equatorial mount is capable of retaining the target to within an arcsecond-size box. The Andor iKon-L $BV$ CCD camera has a wide 22x22′′ FoV and can take images in the Johnson/Cousins $UBV$ and Sloan $g'$, $r'$ and $i'$ filters; the practically measurable magnitude of the photometry for 60s exposures (SNR=5) is $Rc \sim 19.3m$ (Berdnikov et al. 2020).

4 Astroclimatic monitor

The ASM facility is an oldest one at CMO and operates continuously since the end of 2007. It has collected a long series of atmospheric turbulence profile measurements together with the sky background and extinction and the site weather conditions data. In 2020, the ASM started to feed the flexible target scheduler software for SAI2.5 operators. In 2018–2020, the weather statistics implies a median seeing of 1′′02 and 1300–1400 hr of clear sky per year.
5 Highlight results of CMO SAI MSU

In the recent years, the CMO instruments were used to obtain results in in several topical fields of research, including:

- Variability and size-luminosity relation of AGNs (Oknyansky et al. 2017; Ilić et al. 2020; Cho et al. 2020)
- Study of variable stars associated with maser sources (Sobolev et al. 2019)
- Star-forming regions at the periphery of the supershell surrounding the Cyg OB1 association (Sitnik et al. 2020, 2019; Tatarnikova et al. 2016)
- Optical and NIR-photometry of X-ray sources with black holes, microquasars, pre-main sequence and post-AGB objects (Cherepashchuk et al. 2019a,b)
- Spectroscopy of an ultramassive white dwarf (Pshirkov et al. 2020)
- Colour and polarimetric variability of UXORs; young stellar object jets photometry (Dodin et al. 2020a, 2019; Berdnikov et al. 2017)
- Analysis of temporal evolution of the circumstellar envelopes of evolved stars at high angular resolution (Safonov et al. 2019b; Fedoteva et al. 2020)
- Spectral characterization of solar system bodies (Busarev et al. 2018)
- Near-infrared photometry of superthin edge-on galaxies (Bizyaev et al. 2020)
- Spectral characterization and identification of SRG/eRosita sources (Dodin et al. 2020b)
- High-accuracy monitoring of exoplanet transits (Benni et al. 2020).

In 2021, the 2.5-m reflector of CMO SAI is expected to take commissioning and start operating as part of the Russian large telescopes program.

Acknowledgements. The construction and development of CMO SAI MSU have been supported by M.V. Lomonosov Moscow State University Program of Development, RSF grants 17-12-01241 and 16-12-10519, RFBR grants 16-32-60065, and the Leading Scientific School of MSU “Physics of stars, galaxies and relativistic objects”. This work is supported by the Ministry of science and higher education under the contracts 075-15-2020-780 (exoplanet transits) and 075-15-2020-778 (observations of objects with extreme energy release) in the framework of the Large scientific projects program within the national project “Science”.
