On rate of convergence to the Poisson law
of the number of cycles
in the generalized random graphs

Sergey G. Bobkov, Maria A. Danshina, Vladimir V. Ulyanov

Abstract Convergence of order $O(1/\sqrt{n})$ is obtained for the distance in total variation between the Poisson distribution and the distribution of the number of fixed size cycles in generalized random graphs with random vertex weights. The weights are assumed to be independent identically distributed random variables which have a power-law distribution. The proof is based on the Chen–Stein approach and on the derived properties of the ratio of the sum of squares of random variables and the sum of these variables. These properties can be applied to other asymptotic problems related to generalized random graphs

1 Introduction

Complex networks attract increasing attention of researchers in various fields of science. In last years numerous network models have been proposed. Since the uncertainty and the lack of regularity in real-world networks, these models are usually random graphs. Random graphs were first defined in [10], and independently by Gilbert in [12]. The suggested models are closely related: there are $n$ isolated vertices and every possible edge occurs independently with probability $p : 0 < p < 1$.
It is assumed that there are no self-loops. Later the models were generalized. A natural generalization of the ErdHos–Rényi random graph is that the equal edge probabilities are replaced by probabilities depending on the vertex weights. Vertices with high weights are more likely to have more neighbors than vertices with small weights. Vertices with extremely high weights could act as the hubs observed in many real-world networks.

The following generalized random graph (GRG) model was first introduced by Britton et al., see [5]. Let \( V = \{1, 2, \ldots, n\} \) be the set of vertices, and \( W_i > 0 \) be the weight of vertex \( i \), \( 1 \leq i \leq n \). The edge probability of the edge between any two vertices \( i \) and \( j \), for \( i \neq j \), is equal to

\[
p_{ij} = \frac{W_i W_j}{L_n + W_i W_j}
\]

and \( p_{ii} = 0 \) for all \( i \leq n \). Here \( L_n = \sum_{i=1}^{n} W_i \) denotes the total weight of all vertices. The weights \( W_i, i = 1, 2, \ldots, n \) can be taken to be deterministic or random. If we take all \( W_i \) as the same constant: \( W_i = n \lambda/(n - \lambda) \) for some \( 0 \leq \lambda \leq n \), it is easy to see that \( p_{ij} = \lambda/n \) for all \( 1 \leq i < j \leq n \). That is, the ErdHos–Rényi random graph with \( p = \lambda/n \) is a special case of the GRG.

There are many versions of the GRG, such as Poissonian random graph (introduced by Norros and Reittu in [20] and studied by Bhamidi et al. [3]), rank-1 inhomogeneous random graph (see [4]), random graph with given prescribed degrees (see [8]), Chung–Lu model of heterogeneous random graph (see [7]) etc. The Chung–Lu model is the closest to the model of generalized random graph. Two vertices \( i \) and \( j \) are connected with probability \( p_{ij} = W_i W_j/L_n \) and independently of other pairs of vertices, where \( W = (W_1, W_2, \ldots, W_n) \) is a given sequence. It is necessary to assume that \( W_i^2 \leq L_n \), for all \( i \). Under some common conditions (see [16]), all of the above mentioned versions of the GRG are asymptotically equivalent, meaning that all events have asymptotically equal probabilities. The updated review on the results about these inhomogeneous random graphs see in Chapters 6 in [13].

One of the problems that arise in real networks of various nature is the spread of the virus. In [6], the authors proposed an approach called NLDS (nonlinear dynamic system) for modeling such processes. Consider a network of \( n \) vertices represented by an undirected graph \( G \). Assume an infection rate \( \beta > 0 \) for each connected edge that is connected to an infected vertex and a recovery rate of \( \delta > 0 \) for each infected individual. Define the epidemic threshold \( \tau \) as a value such that

\[
\beta/\delta < \tau \Rightarrow \text{infection dies out over time}
\]

\[
\beta/\delta > \tau \Rightarrow \text{infection survives and becomes an epidemic.}
\]

\( \tau \) is related to the adjacency matrix \( A \) of the graph. The matrix \( A = [a_{ij}] \) is an \( n \times n \) symmetric matrix defined as \( a_{ij} = 1 \) if vertices \( i \) and \( j \) are connected by an edge, and \( a_{ij} = 0 \) otherwise. Define a walk of length \( k \) in \( G \) from vertex \( v_0 \) to \( v_k \) to be an ordered sequence of vertices \( (v_0, v_1, \ldots, v_k) \), with \( v_i \in V \), such that \( v_i \) and \( v_{i+1} \) are connected for \( i = 0, 1, \ldots, k - 1 \). If \( v_0 = v_k \), then the walk is closed. A closed walk
with no repeated vertices (with the exception of the first and last vertices) is called a cycle. For example, triangles, quadrangles and pentagons are cycles of length three, four, and five, respectively. In the following, the cycle will be denoted by the first \( k \) vertices, without specifying the vertex \( v_k \), which is the same as \( v_0: (v_0, v_1, \ldots, v_{k-1}) \).

In Theorem 1 in [6] it has been stated that \( \tau \) is equal to \( 1/\lambda_1 \), where \( \lambda_1 \) is the largest eigenvalue of the adjacency matrix \( A \). The following lower bound for \( \lambda_1(A) \), was shown in [21]

\[
\lambda_1(A) \geq \frac{6\Delta + \sqrt{36\Delta^2 + 32e^2/n}}{4e},
\]

where \( n, e, \) and \( \Delta \) the number of vertices, edges and triangles in \( G \), resp. Moreover, using information about the cycle numbers of higher orders one can get more precise upper bounds for \( \tau \).

In [14] the central limit theorems were proved for the total number of edges in GRG. There are also many results on asymptotic properties of the number of triangles in homogeneous cases. For example, for the ErdHos–Rényi random graph, the upper tails for the distribution of the triangle number had been studied in [2], [9], [15], [17]. Recently, in [18] it was shown for GRG model that asymptotic distribution of the triangle number converges to a Poisson distribution under strong assumption that the vertex weights are bounded random variables.

A lot of real-world networks such as social or computer networks in Internet, see e.g. [11], follow a so-called scale-free graph model, see Ch.1 in [13]. In Ch.6 in [13] it was shown that when the vertex weights have approximately a power-law distribution, the GRG model leads to scale-free random graph.

In the present paper, we prove not only the convergence but we get the convergence rate of order \( O(1/\sqrt{n}) \) for the distance in total variation between the Poisson distribution and the distribution of the number of fixed size cycles in GRG with random vertex weights. The weights are assumed to be independent identically distributed random variables which have a power-law distribution. The proof is based on the Chen–Stein approach and on the derived properties of the ratio of the sum of squares of random variables and the sum of these variables. These properties can be applied to other asymptotic problems related to GRG.

The main results are formulated in Section 2. For their proofs, see Section 4. Section 3 contains auxiliary lemmas, some of which are of independent interest.

## 2 Main results

Let \( \{1, 2, \ldots, n\} \) be the set of vertices, and \( W_i \) be a weight of vertex \( i : 1 \leq i \leq n \). The probability of the edge between vertices \( i \) and \( j \) is defined in [1]. Let \( W_i, i = 1, 2, \ldots, n \), be independent identically distributed random variables distributed as a random variable \( W \). For \( k \geq 3 \), denote by \( I(k) \) the set of potential cycles of length \( k \). We have that the number of elements in \( I(k) \) is equal to \( (n)_k/(2k) \), where \( (n)_k = n(n-1)\ldots(n-k+1) \) is the number of ways to select \( k \) distinct vertices in order, and the factor \( 1/(2k) \) appears since, for \( k > 2 \), a permutation
of \( k \) vertices corresponds to a choice of a cycle in \( I(k) \) together with a choice of any of two orientations and \( k \) starting points. For example, all six cycles \( \{1, 3, 4\}, \{3, 4, 1\}, \{4, 1, 3\}, \{4, 3, 1\}, \{1, 4, 3\}, \{3, 1, 4\} \) are, in fact, one cycle of length 3. For \( \alpha \in I(k) \), let \( Y_\alpha \) be the indicator that \( \alpha \) occurs as a cycle in GRG. For example,

\[
P^I_{13}Y_{f1} = p_{13}p_{34}p_{41}.
\]

For any integer-valued non-negative random variables \( Y \) and \( Z \), denote the total variation distance between their distributions \( \ell^I(Y) \) and \( \ell^I(Z) \) by

\[
\| \ell^I(Y) - \ell^I(Z) \| = \sup_{\| h \|_1 = 1} |\mathbb{E}h(Y) - \mathbb{E}h(Z)|,
\]

where \( h \) is any real function defined on \( f0\) – \( f2\) – ••• g

\[
\text{Remark 1} \quad \text{Relation (3) holds under condition that \( W \) has power-law distribution. The condition on the tail behavior of the distribution of \( W \) can be replaced by stronger moment condition: the finiteness of expectation \( \mathbb{E}W^2/\mathbb{E}W \).}
\]

\[
\text{Remark 2} \quad \text{Recently in \cite{18} it was proved by method of moments the convergence in distribution of the number of triangles \( S_n(3) \) in a generalized random graphs to the Poisson random variable \( Z_3 \) under assumption that the vertex weights \( W_i \)-s are bounded random variables. In Theorem 1 we have used the Chen–Stein approach, see e.g. \cite{1} and \cite{2}. This allows us not only to extend the convergence result to cycles of any fixed length \( k \) but also to get the rate of convergence. Moreover, we replace the assumption about the boundness of \( W_i \)-s with the condition that \( W_i \) has a power-law distribution. As we noted in the Introduction, this condition better matches real-world networks.}
\]

Figures 1 and 2 illustrate the results of Theorem 1 with the example of the number of triangles and quadrilaterals distributions.

The next results are not directly connected with number of cycles in GRG. They are an important part of the proof of the Theorem 1. At the same time the results are of independent interest. They describe the asymptotic properties of ratio of a sum of the squares of \( n \) i.i.d. random variables and a sum of these random variables. These properties can be applied to other asymptotic problems related to GRG.

Given i.i.d. positive random variables \( X, X_1, \ldots, X_n \), define the statistics

\[
T_n = \frac{X_1^2 + \cdots + X_n^2}{X_1 + \cdots + X_n}.
\]
Assume that $X$ has a finite second moment, so that, by the law of large numbers, with probability one
$$
\lim_{n \to \infty} T_n^p = \left( \frac{\mathbb{E}X^2}{\mathbb{E}X} \right)^p
$$
for any $p \geq 1$. Here we describe the tail-type and moment-type conditions which ensure that this convergence also holds on average.

**Theorem 2** Given an integer $p \geq 2$, the convergence
$$
\lim_{n \to \infty} \mathbb{E}T_n^p = (\mathbb{E}X^2/\mathbb{E}X)^p \tag{5}
$$
is equivalent to the tail condition
$$
\mathbb{P}\{X \geq x\} = o(x^{-p-1}) \text{ as } x \to \infty. \tag{6}
$$
Moreover, if $\mathbb{P}\{X \geq x\} = O(x^{-p-3/2})$ as $x \to \infty$, then
$$
\mathbb{E}T_n^p - (\mathbb{E}X^2/\mathbb{E}X)^p = O(n^{-1/2}) \tag{7}
$$
The finiteness of the moment $\mathbb{E}X^{p+1}$ is sufficient for (5) to hold, while the finiteness of the moments $\mathbb{E}X^q$ is necessary for any real value $1 \leq q < p + 1$.

Let $M_n = \max_{1 \leq i \leq n} X_i$. For $p \geq 2$, define
$$
R_n^{(p)} = T_n^p M_n^2 / (X_1 + X_2 + \ldots + X_n). \tag{8}
$$
By the law of large numbers, $R_n^{(p)} \to 0$ as $n \to \infty$ a.s., under mild moment assumptions. The next theorem gives the order of convergence of $\mathbb{E}R_n^{(p)}$ to zero under tail-type and moment-type conditions.

---

**Fig. 1** Histogram of the number of triangles in GRG with 2000 vertices. The vertex weights $W_i = scale \times Y + loc$, where $loc = 1$, $scale = 10$ and $Y \sim \text{Pareto} (9.5)$ for all $i \leq 2000$. The number of realizations is 400.

**Fig. 2** Q-Q plot for the number of quadrilaterals in GRG with 2000 vertices and the Poisson variable $Pois(2880.16)$. The vertex weights $W_i = scale \times Y + loc$, where $loc = 1$, $scale = 10$ and $Y \sim \text{Pareto} (9.5)$ for all $i \leq 2000$. The number of realizations is 400.
Theorem 3 Given an integer \( p \geq 2 \), if \( \mathbb{P}(X \geq x) = O(x^{-p+1/2}) \) as \( x \to +\infty \), then

\[
\mathbb{E} R_n^{(p)} = O(n^{-1/2}).
\] (9)

When \( p > 8 \) and \( \mathbb{E} X^{p+4} \) is finite, the rate can be improved to

\[
\mathbb{E} R_n^{(p)} = O(n^{-(p-2)/(p+4)}).
\] (10)

Moreover, if \( \mathbb{E} e^{cX} < \infty \) for some \( c > 0 \), then

\[
\mathbb{E} R_n^{(p)} = O\left(\frac{(\log n)^2}{n}\right).
\] (11)

3 Auxiliary lemmas

Lemma 1 Let \( S_n = \eta_1 + \cdots + \eta_n \) be the sum of independent random variables \( \eta_k \geq 0 \) with finite second moment, such that \( \mathbb{E} S_n = n \) and \( \text{Var}(S_n) = \sigma^2 n \). Then, for any \( 0 < \lambda < 1 \), one has

\[
\mathbb{P}\{S_n \leq \lambda n\} \leq \exp\left\{- \frac{(1 - \lambda)^2}{2 \left[ \sigma^2 + \max_k (\mathbb{E} \eta_k)^2 \right]} n\right\}.
\] (12)

Proof We use here the standard arguments. Fix a parameter \( t > 0 \). We have

\[
\mathbb{E} e^{-tS_n} \geq e^{-t \lambda n} \mathbb{P}\{S_n \leq \lambda n\}.
\]

Every function \( u_k(t) = \mathbb{E} e^{-t \xi_k} \) is positive, convex, and admits Taylor’s expansion near zero up to the quadratic form, which implies that

\[
u_k(t) \leq 1 - t \mathbb{E} \xi_k + \frac{t^2}{2} \mathbb{E} \xi_k^2 \leq \exp\left\{- t \mathbb{E} \xi_k + \frac{t^2}{2} \mathbb{E} \xi_k^2 \right\}.
\]

Multiplying these inequalities, we get

\[
\mathbb{E} e^{-tS_n} \leq \exp\left\{ - tn + \frac{bt^2}{2} \right\}, \quad b = \sum_{k=1}^{n} \mathbb{E} \xi_k^2.
\]

The two bounds yield

\[
\mathbb{P}\{S_n \leq \lambda n\} \leq \exp\left\{ - (1 - \lambda) nt + \frac{bt^2}{2} / n^2 \right\},
\]

and after optimization over \( t \) (in fact, \( t = \frac{1 - \lambda}{b} n \)), we arrive at the exponential bound

\[
\mathbb{P}\{S_n \leq \lambda n\} \leq \exp\left\{ - \frac{(1 - \lambda)^2}{2b} n^2 \right\}.
\]
Rate of convergence to the Poisson law of the numbers of cycles in GRG

Note that
\[ b = \text{Var}(S_n) + \sum_{k=1}^{n} (\mathbb{E} \xi_k)^2 \leq \left( \sigma^2 + \max_k (\mathbb{E} \xi_k)^2 \right) n, \]
and \([12]\) follows.

For further lemmas we need additional notation.

Denote by \( F(x) = \mathbb{P}\{X \leq x\} \) (\( x \in \mathbb{R} \)) the distribution function of the random variable \( X \) and put
\[ \epsilon_q(x) = x^q (1 - F(x)), \quad x \geq 0, \; q > 0. \]

Raising the sum \( U_n = X_1^2 + \cdots + X_n^2 \) to the power \( p \) with \( n \geq 2p \), we have
\[
U_n^p = \sum X_{i_1}^2 \cdots X_{i_p}^2,
\]
where the summation is performed over all collections of numbers \( i_1, \ldots, i_p \in \{1, \ldots, n\} \). For \( r = 1, \ldots, p \), we denoted by \( C(p, r) \) the collection of all tuples \( \gamma = (\gamma_1, \ldots, \gamma_r) \) of positive integers such that \( \gamma_1 + \cdots + \gamma_r = p \). For any \( \gamma \in C(p, r) \), there are \( n(n-1) \cdots (n-r+1) \) sequences \( X_{i_1}, \ldots, X_{i_r} \) with \( r \) distinct terms that are repeated \( \gamma_1, \ldots, \gamma_r \) times, resp. Therefore, by the i.i.d. assumption,
\[
\mathbb{E} T_n^p = \sum_{r=1}^{p} \frac{n(n-1) \cdots (n-r+1)}{n^p} \sum_{\gamma \in C(p, r)} \mathbb{E} \xi_n(\gamma),
\]
where
\[ \xi_n(\gamma) = X_1^{2\gamma_1} \cdots X_r^{2\gamma_r} / \left( \frac{1}{n} S_r + \frac{1}{n} S_{n-r} \right)^p \]
and
\[ S_r = X_1 + \cdots + X_r, \quad S_{n-r} = X_{n+1} + \cdots + X_n. \]

In the following lemmas, without loss of generality, let \( \mathbb{E} X = 1 \).

**Lemma 2** For the boundedness of the sequence \( \mathbb{E} T_n^p \) it is necessary that the moment \( \mathbb{E} X^p \) be finite. Moreover, for the particular collection \( \gamma = (p) \) with \( r = 1 \), we have
\[
\mathbb{E} \xi_n(\gamma) \geq 2^{-p} n^p \mathbb{E} X^p 1_{\{X \geq n\}}.
\]

**Proof** Since \( \xi_n(\gamma) = X_1^{2p} / \left( \frac{1}{n} X_1 + \frac{1}{n} S_{n,1} \right)^p \), applying Jensen’s inequality, we get
\[
\mathbb{E} \xi_n(\gamma) \geq \mathbb{E} X_1 \frac{X_1^{2p}}{\left( \frac{1}{n} X_1 + \frac{1}{n} \mathbb{E} S_{n,1} S_{n,1} \right)^p} \geq \mathbb{E} \left( \frac{X^{2p}}{\left( \frac{1}{n} X + \frac{n-1}{n} \right)^p} \right) \geq 2^{-p} n^p \mathbb{E} X^p 1_{\{X \geq n\}}.
\]
Lemma 3 If \( E X^p \) is finite, then \( E \xi_n \to (E X^2)^p \) as \( n \to \infty \), where

\[
\xi_n = X_1^2 \ldots X_p^2 / \left( \frac{1}{n} S_p + \frac{1}{n} S_{n,p} \right)^p.
\]

Proof Using \( X_1 \ldots X_p \leq S_p^p \), we have \( \xi_n \leq S_p^2 / \left( \frac{1}{n} S_n \right)^p \leq n^p S_p^p \). Hence

\[
E \xi_n 1_{\Lambda_{n,p}} \leq n^p E S_p^p P(A_{n,p}) = o(e^{-cn})
\]

for some constant \( c > 0 \) independent of \( n \). Here, we applied \([17]\) with \( r = p \) and Lemma \([2]\) which ensures that \( E S_p^2 \) is finite. Further, \( \xi_n 1_{B_{n,p}} \leq 2^p X_1^2 \ldots X_p^2 \). Hence, the random variables \( \xi_n 1_{B_{n,p}} \) have an integrable majorant. Since also \( \xi_n \to X_1^2 \ldots X_p^2 \) (the law of large numbers) and \( 1_{B_{n,p}} \to 1 \) a.s. (implied by \([17]\)), one may apply the Lebesgue dominated convergence theorem, which gives \( E \xi_n 1_{B_{n}} \to (E X^2)^p \). Together with \([19]\), we get \( E \xi_n \to (E X^2)^p \).

Lemma 4 If the moment \( E X^p \) is finite, then for any \( \gamma = (\gamma_1, \ldots, \gamma_r) \in C(p, r) \),

\[
E \xi_n(\gamma) = 4^p \frac{X_1^{2\gamma_1} \ldots X_p^{2\gamma_r}}{\left( \frac{1}{n} S_r + 1 \right)^p} + o(1).
\]

Proof Using an elementary bound \( X_1^{2\gamma_1} \ldots X_p^{2\gamma_r} \leq (X_1 + \ldots + X_r)^{2\gamma_1 + \ldots + 2\gamma_r} = S_p^2 \) and applying Jensen’s inequality, we see that \( \xi_n(\gamma) \leq n^p S_p^2 \leq n^p r^p-1 (X_1^p + \ldots + X_p^p) \). Hence

\[
E \xi_n(\gamma) 1_{\Lambda_{n,r}} \leq n^p r^{p-1} \sum_{k=1}^r E X_k^p 1_{\Lambda_{n,r}} = n^p r^p E X^p P(A_{n,r}) = o(e^{-cn}).
\]

On the other hand, on the set \( B_{n,r} \) there is a pointwise bound

\[
\xi_n(\gamma) 1_{B_{n,r}} \leq \frac{X_1^{2\gamma_1} \ldots X_p^{2\gamma_r}}{\left( \frac{1}{n} S_r + \frac{n-r}{2n} \right)^p} \leq 4^p \frac{X_1^{2\gamma_1} \ldots X_p^{2\gamma_r}}{\left( \frac{1}{n} S_r + 1 \right)^p}.
\]

Our task is reduced to the estimation of the expectation on the right-hand side of \([21]\). Let us first consider the estimation of the shortest collection \( \gamma = (p) \) of length \( r = 1 \).
Lemma 5 Under the condition (6),

\[ \mathbb{E} \frac{X_1^{2p}}{(\frac{1}{n} X_1 + 1)^p} = o(n^{p-1}). \]  

(22)

In addition, if \( \mathbb{P}\{X \geq x\} = O(x^{-q}) \) for some real value \( q \) in the interval \( p < q < 2p \), then

\[ \mathbb{E} \frac{X_1^{2p}}{(\frac{1}{n} X_1 + 1)^p} = O(n^{2p-q}). \]  

(23)

Proof We have

\[ \mathbb{E} \frac{X_1^{2p}}{(\frac{1}{n} X_1 + 1)^p} = \mathbb{E} \frac{X_1^{2p}}{(\frac{1}{n} X_1 + 1)^p} 1\{X_1 \geq n\} + \mathbb{E} \frac{X_1^{2p}}{(\frac{1}{n} X_1 + 1)^p} 1\{X_1 < n\} \]

\[ \leq n^p \mathbb{E} X^p 1\{X \geq n\} + \mathbb{E} X^{2p} 1\{X < n\} \]

In view of (6), to derive (22), it remains to bound the last expectation by \( o(n^{p-1}) \). Integrating by parts and assuming that \( x = n \) is the point of continuity of \( F(x) \), we have using \( \epsilon \to 0^+ \) as \( x \to \infty \),

\[ \mathbb{E} X^{2p} 1\{X < n\} = -n^{2p} p (1 - F(n)) + 2p \int_0^n x^{2p-1} (1 - F(x)) \, dx \]

\[ \leq 2p \int_0^n x^{p-2} \epsilon_{p+1} (x) \, dx = o(n^{p-1}), \]  

(24)

For the second assertion (23), we similarly have

\[ \mathbb{E} X^{2p} 1\{X > n\} \leq 2p \int_0^n x^{2p-1} - q \epsilon_q (x) \, dx = O(n^{2p-q}), \]

\[ \mathbb{E} X^p 1\{X \geq n\} = O(n^{p-q}) + p \int_n^\infty x^{p-1} - q \epsilon_q (x) \, dx = O(n^{p-q}). \]

Lemma 6 Let \( \gamma = (\gamma_1, \ldots, \gamma_r) \in \mathbb{C}(p, r), 2 \leq r \leq p - 1 \). Under (6), we have

\[ \mathbb{E} \frac{X_1^{2\gamma_1} \cdots X_r^{2\gamma_r}}{(\frac{1}{n} S_r + 1)^p} = o(n^{p-r-1} \log n). \]  

(25)

Proof If all \( \gamma_i \leq p/2 \), there is nothing to prove, since then

\[ \mathbb{E} \frac{X_1^{2\gamma_1} \cdots X_r^{2\gamma_r}}{(\frac{1}{n} S_r + 1)^p} \leq \mathbb{E} X_1^{2\gamma_1} \cdots \mathbb{E} X_r^{2\gamma_r} \leq (\mathbb{E} X^p)^r. \]

In the other case, suppose for definiteness that \( \gamma_1 \) is the largest number among all \( \gamma_i \)'s. Necessarily \( \gamma_1 > p/2 \) and \( \gamma_i < p/2 \) for all \( i \geq 2 \). Since \( S_r < n \) implies \( X_1 < n \),
we similarly have
\[
\mathbb{E} \frac{X_i^{2\gamma} \cdots X_r^{2\gamma}}{\left( \frac{1}{n} S_r + 1 \right)^p} 1_{\{S_r < n\}} \leq (\mathbb{E}X^p)^{r-1} \mathbb{E} X_i^{2\gamma} 1_{\{X < n\}}.
\]

To bound the last expectation, note that \( r-1 \leq \gamma_2 + \cdots + \gamma_r < p/2 \), so that \( p \geq 2r - 1 \). Hence, if \( x = n \) is the point of continuity of \( F(x) \), similarly to (24) we get
\[
\mathbb{E} X_i^{2\gamma} 1_{\{X < n\}} \leq 2\gamma_1 \int_0^n x^{2\gamma_1 - p - 2} e_{p+1}(x) \, dx.
\]  
(26)

But since \( \gamma_1 \leq p - r + 1 \),
\[
\int_1^n x^{2\gamma_1 - p - 2} e_{p+1}(x) \, dx \leq \int_1^n x^{p-2r} e_{p+1}(x) \, dx = o(n^{p-2r+1}),
\]  
(27)

if \( p \geq 2r \) or \( p \leq 2r - 2 \), which is even stronger than the rate \( o(n^{p-r-1}) \). In the remaining case \( p = 2r - 1 \), the last integral is \( o(\log n) \). This proves (25) for the part of the expectation restricted to the set \( S_r < n \), that is,
\[
\mathbb{E} \frac{X_i^{2\gamma} \cdots X_r^{2\gamma}}{\left( \frac{1}{n} S_r + 1 \right)^p} 1_{\{S_r < n\}} = o(n^{p-r-1} \log n).
\]  
(28)

Note that the logarithmic term cannot be removed in the special situation where \( p = 3 \), \( r = 2 \), \( \gamma_1 = 2 \), \( \gamma_2 = 1 \), in which case the last integral in (27) becomes \( \int_1^n x^{p-2r} e_{p+1}(x) \, dx \).

Turning to the expectation over the complementary set \( S_r \geq n \), introduce the events
\[
\Omega_i = \left\{ X_i \geq \max_{j \neq i} X_j \right\}, \quad i = 1, \ldots, r.
\]

On every such set, \( X_i = S_r \leq rX_i \). In particular, \( S_r \geq n \) implies \( X_i \geq n/r \). Hence, together with (28), (25) would follow from the stronger assertion
\[
\mathbb{E} \frac{X_i^{2\gamma} \cdots X_r^{2\gamma}}{X_i^p} 1_{\{X_i \geq n\} \cap \Omega_i} = o(n^{r-1})
\]  
(29)

with an arbitrary index \( 1 \leq i \leq r \).

Case 1. \( i \geq 2 \). If we fix any values \( X_1 = x_1 \) and \( X_i = x_i \), then the expectation with respect to \( X_j, j \neq i \), in (29) will yield a bounded quantity (since the \( p \)-moment is finite). Hence (29) is simplified to
\[
\mathbb{E} X_i^{2\gamma} X_i^{2\gamma_p - p} 1_{\{X_i \geq n\} \cap \{X_i \geq x_i\}} = o(n^{r-1}).
\]  
(30)

Here, the expectation over \( X_1 \) may be carried out and estimated similarly to (26), by replacing \( n \) with \( x_i \). Namely,
Without loss of generality, let $\delta(x_i) \rightarrow 0$ as $x_i \rightarrow \infty$ (this assertion may be strengthened when $2\gamma_1 - p = 1$). Hence, the expectation in (30) is bounded by
\[
\mathbb{E} X_1^{2\gamma_1 + 2\gamma_1 - 2p} \delta(X_i) 1_{\{X_i \geq n\}} \leq \delta_n \mathbb{E} X_i^{2\gamma_1 + 2\gamma_1 - 2p} 1_{\{X_i \geq n\}} = \delta_n n^{2\gamma_1 + 2\gamma_1 - 2p} (1 - F(n)) + c_i \delta_n \int_{-\infty}^{\infty} x^{2\gamma_1 + 2\gamma_1 - 2p - 1} (1 - F(x)) \, dx \\
= o(n^{2\gamma_1 + 2\gamma_1 - 3p - 1}) + c_i \delta_n \int_{-\infty}^{\infty} x^{2\gamma_1 + 2\gamma_1 - 3p - 2} e_{p+1}(x) \, dx \\
= o(n^{2\gamma_1 + 2\gamma_1 - 3p - 1}),
\]
where $\delta_n = \sup_{x \geq n} \delta(x) \rightarrow 0$. To obtain (30), it remains to check that $2\gamma_i + 2\gamma_1 - 3p - 1 \leq -r - 1$. And indeed, since $p = \gamma_i + \gamma_1 + \sum_{j \neq i, 1} \gamma_j \geq \gamma_i + \gamma_1 + (r - 2)$, the desired relation would follow from $2(p - (r - 2)) - 3p - 1 \leq -r - 1$, that is, $p + r \geq 4$ (which is true).

Case 2. Let $i = 1$. If we fix any value $X_1 = x_1$, the expectation with respect to $X_j$, $j \neq 1$, will yield a bounded quantity (since the $p$-moment is finite). Hence (39) is simplified to
\[
\mathbb{E} X_1^{2\gamma_1 - p} 1_{\{X_i \geq n\}} = o(n^{-r-1}).
\]
Here, the expectation may be estimated similarly. Namely,
\[
\mathbb{E} X_1^{2\gamma_1 - p} 1_{\{X_i \geq n\}} = \int_{-\infty}^{\infty} x^{2\gamma_1 - p} dF(x) \\
= o(n^{2\gamma_1 - 2p - 1}) + \int_{-\infty}^{\infty} x^{2\gamma_1 - 2p - 2} e_{p+1}(x) \, dx = o(n^{2\gamma_1 - 2p - 1}).
\]
It remains to see that $2\gamma_1 - 2p - 1 \leq -r - 1$. Again, since $\gamma_1 \leq p - (r - 1)$, the latter would follow from $2(p - (r - 1)) - 2p - 1 \leq -r - 1$, which is the same as $r \geq 2$. \qed

We now consider the lemmas which enable us to get a bound for $\mathbb{E} R_n^{(p)}$, see (8).

Without loss of generality, let $\mathbb{E} X = 1$ and $n \geq 2p$.

Introduce additional notation: $M_n = \max_{1 \leq i \leq n} X_i$, $(1 \leq r \leq p)$.

Recall that there is the representation (13) but instead of (14) we write now
\[
\mathbb{E} R_n^{(p)} = \sum_{r=1}^{p} \frac{n(n-1) \ldots (n-r+1)}{n^{p+1}} \sum_{\gamma \in \mathcal{C}(p,r)} \mathbb{E} \eta_n(\gamma) M_n^r, \quad (31)
\]
where
\[
\eta_n(\gamma) = \frac{X_1^{2\gamma_1} \ldots X_r^{2\gamma_r}}{(\frac{1}{n} S_r + \frac{1}{n} S_{r,r})^{p+1}}.
\]

In order to bound the expectations on the right-hand side of (31), we use again the events $A_{n,r}$ and $B_{n,r}$, see (16). From elementary inequalities $M_n \leq S_n$ and
\[ X_1^{2\gamma_1} \cdots X_r^{2\gamma_r} \leq (X_1 + \cdots + X_r)^{2\gamma_1 + \cdots + 2\gamma_r} \leq S_n^{2p}, \]

it follows that \( \eta_n(\gamma)M_n^2 \leq n^{p+1}S_n^{p+1} \leq 2^p n^{p+1} (S_r^{p+1} + S_{n,r}^{p+1}) \), implying

\[ \mathbb{E}\eta_n(\gamma)M_n^2 1_{A_{n,r}} \leq 2^p n^{p+1} \left( \mathbb{E}S_r^{p+1} \mathbb{P}(A_{n,r}) + \mathbb{E}S_{n,r}^{p+1} \mathbb{E}S_r^{p+1} 1_{A_{n,r}} \right). \] (32)

Here, by Lemma 1 with \( \lambda = 1/2 \) and using \( n - r \geq \frac{1}{2} n \), we have

\[ \mathbb{P}(A_{n,r}) \leq \exp \left\{ - \frac{1}{16} \frac{1}{b^2} \eta \right\}, \quad b^2 = \mathbb{E}X^2. \] (33)

Also, assuming that the moment \( \mathbb{E}X^{p+2} \) is finite and applying the Hölder inequality with exponents \( (p + 2)/(p + 1) \) and \( p + 2 \), one may bound the last expectation in (32) as

\[ \mathbb{E}S_{n,r}^{p+1} 1_{A_{n,r}} \leq \left( \mathbb{E}S_n^{p+2} \right)^{\frac{1}{p+1}} \left( \mathbb{E}A_{n,r} \right)^{\frac{1}{p+1}}. \]

By Jensen inequality, \( \mathbb{E}S_{n,r}^{p+2} \leq r^{p+1} \mathbb{E}X^{p+2} \). Applying this in (32), the inequality (33) yields an exponential bound

\[ \mathbb{E}\eta_n(\gamma)M_n^2 1_{A_{n,r}} \leq e^{-cn} \] (34)

with some constant \( c > 0 \) which does not depend on \( n \).

As for the set \( B_{n,r} \), we use on it a point-wise upper bound

\[ \eta_n(\gamma) \leq 2^{p+1} X_1^{2\gamma_1} \cdots X_r^{2\gamma_r} / (\frac{1}{n} S_r + 1)^{p+1}. \]  

One may also use \( M_n \leq M_r + M_{n,r} \leq S_r + M_{n,r} \), implying, by Jensen’s inequality, \( M_n^2 \leq (r + 1) (X_1^2 + \cdots + X_r^2 + M_{n,r}^2) \). It gives

\[ \mathbb{E}\eta_n(\gamma)M_n^2 1_{B_{n,r}} \leq 2^{p+1}(r + 1) \sum_{k=1}^r \mathbb{E} \frac{X_1^{2\gamma_1} \cdots X_r^{2\gamma_r}}{(\frac{1}{n} S_r + 1)^{p+1}} X_k^2 
+ 2^{p+1}(r + 1) \sum_{k=1}^r \mathbb{E} \frac{X_1^{2\gamma_1} \cdots X_r^{2\gamma_r}}{(\frac{1}{n} S_r + 1)^{p+1}} M_{n,r}^2 \] (35)

Without an essential loss, the last expectation \( \mathbb{E}M_{n,r}^2 \) may be replaced with \( \mathbb{E}M_n^2 \). The second last expectation was considered in Lemmas 2-4 under the condition (6), which holds as long as the moment \( \mathbb{E}X^{p+1} \) is finite. The third last expectation in (35), due to an additional factor \( X_k^2 \), dominates the second last and needs further consideration under stronger moment assumptions. Recalling (33) and returning to (31), let us summarize in the following statement.

**Lemma 7** If the moment \( \mathbb{E}X^{p+2} \) is finite, then
Rate of convergence to the Poisson law of the numbers of cycles in GRG

\[ c E R_n^{(p)} \leq e^{-cn} + \max_{1 \leq k \leq r} \max_{\gamma \in C(p,r)} \frac{1}{n^{p-r+1}} \mathbb{E} \frac{X_1^{2r} \ldots X_r^{2r}}{(\frac{1}{p} S_r + 1)^{p+1}} X_k^2 \]

with some constant \( c > 0 \) which does not depend on \( n \geq 2p \).

In order to obtain polynomial bounds for the expectations in (36) under suitable moment or tail assumptions, we need to develop corresponding analogs of Lemmas 5–6. We will consider separately the cases \( r = 1, p \), and \( 2r \geq p \) under the tail condition

\[ \mathbb{P}\{X \geq x\} = O(1/x^{p+\alpha}) \quad \text{as} \quad x \to \infty, \quad (37) \]

where \( \alpha > 0 \) is a parameter. It implies that the moments \( \mathbb{E}X^q \) are finite for all \( q < p+\alpha \) and is fulfilled as long as the moment \( \mathbb{E}X^{p+\alpha} \) is finite. Put \( \varepsilon(x) = x^{p+\alpha} (1 - F(x)) \), where \( F \) denotes the distribution function of the random variable \( X \).

**Lemma 8** Under (37) with \( 1 < \alpha \leq p + 2 \),

\[ \mathbb{E} \frac{X_1^{2p}}{(\frac{1}{p} X_1 + 1)^{p+1}} = O(n^{p-\alpha+2}). \quad (38) \]

Moreover, for any index \( 1 \leq k \leq r \),

\[ \mathbb{E} \frac{X_k^{2p}}{(\frac{1}{p} X_1 + 1)^{p+1}} X_k^2 = O(n^{p-\alpha+2}\log n). \quad (39) \]

**Proof** The expectation in (38) is equal to and satisfies

\[ \mathbb{E} \frac{X_1^{2p}}{(\frac{1}{p} X_1 + 1)^{p+1}} 1\{X_1 \geq n\} + \mathbb{E} \frac{X_3^{2p}}{(\frac{1}{p} X_1 + 1)^{p+1}} 1\{X_1 < n\} \leq n^{p+1} \mathbb{E}X^{p-1} 1\{X \geq n\} + \mathbb{E} X^{2p} 1\{X < n\} \]

Similarly to (24), we get

\[ \mathbb{E} X^{2p} 1\{X < n\} \leq 2p \int_0^n x^{p-\alpha-1} \varepsilon(x) \, dx = O(n^{p-\alpha}), \]

provided that \( \alpha < p \). In the case \( \alpha = p \), the last integral is bounded by \( O(\log n) \). In addition,

\[ \mathbb{E} X^p 1\{X \geq n\} = O(n^{p-\alpha}) + p \int_n^\infty x^{p-\alpha-1} \varepsilon(q) \, dx = O(n^{p-\alpha}). \]
This proves \( (38) \) for \( \alpha \leq p \). If \( p < \alpha \leq p + 2 \), then \( (38) \) holds automatically, since then \( 2p < p + \alpha \) and therefore the expectation in \( (38) \) does not exceed the finite moment \( \mathbb{E}X_1^{2p} \), while the right-hand side is bounded away from zero.

For the second assertion, one may assume that \( k = 1 \), in which case the expectation in \( (39) \) is equal to and satisfies

\[
\mathbb{E} \left( \frac{X_1^{2p+2}}{(\frac{1}{n} S_p + 1)^{p+1}} \right) = \mathbb{E} \left( \frac{X_1^{2p+2}}{(\frac{1}{n} S_p + 1)^{p+1}} 1_{\{X_1 \geq n\}} \right) + \mathbb{E} \left( \frac{X_1^{2p+2}}{(\frac{1}{n} S_p + 1)^{p+1}} 1_{\{X_1 < n\}} \right) \\
\leq n^{p+1} \mathbb{E}X^{p+1} 1_{\{X \geq n\}} + \mathbb{E}X^{2p+2} 1_{\{X < n\}}.
\]

Here, similarly to the previous step, if \( \alpha < p + 2 \),

\[
\mathbb{E}X^{2p+2} 1_{\{X < n\}} \leq 2p \int_0^n x^{p-\alpha+1} \varepsilon(x) \, dx = O(n^{p-\alpha+2}).
\]

In the case \( \alpha = p + 2 \), the last integral is bounded by \( O(\log n) \). In addition,

\[
\mathbb{E}X^{p+1} 1_{\{X \geq n\}} = O(n^{-\alpha+1}) + p \int_n^\infty x^{-\alpha} \varepsilon(x) \, dx = O(n^{-\alpha+1}).
\]

**Lemma 9** If the moment \( \mathbb{E}X^4 \) is finite, then

\[
\mathbb{E} \left( \frac{X_1^2 \ldots X_p^2}{(\frac{1}{n} S_p + 1)^{p+1}} \right) = O(1).
\]

Moreover, for any index \( 1 \leq k \leq p \),

\[
\mathbb{E} \left( \frac{X_1^2 \ldots X_p^2}{(\frac{1}{n} S_p + 1)^{p+1}} X_k^2 \right) = O(1).
\]

This statement is clear. The last expectation does not exceed \( \mathbb{E}X^4 (\mathbb{E}X^2)^{p-1} \) which is finite and does not depend on \( n \).

**Lemma 10** Let \( \gamma = (\gamma_1, \ldots, \gamma_r) \in C(p, r), 2 \leq r \leq p \). Under the condition \( (37) \) with \( 2 < \alpha \leq 4 \), for any index \( 1 \leq k \leq r \),

\[
\mathbb{E} \left( \frac{X_1^{2\gamma_1} \ldots X_r^{2\gamma_r}}{(\frac{1}{n} S_r + 1)^{r+1}} X_k^2 \right) = O(n^{p-r-\alpha+4}). \tag{40}
\]

**Proof** One may reformulate \( (40) \) as the statement

\[
\mathbb{E} \left( \frac{X_1^{2\gamma_1} \ldots X_r^{2\gamma_r}}{(\frac{1}{n} S_r + 1)^{r+1}} \right) = O(n^{p-r-\alpha+4}). \tag{41}
\]
in which \( \gamma = (\gamma_1, \ldots, \gamma_r) \in \mathcal{C}(p + 2, r) \). If all \( \gamma_i \leq \frac{p+2}{2} \), there is nothing to prove, since

\[
\mathbb{E} \frac{X_1^{2\gamma_1} \cdots X_r^{2\gamma_r}}{\left(\frac{1}{n} S_r + 1\right)^{p+1}} \leq \mathbb{E} X_1^{2\gamma_1} \cdots X_r^{2\gamma_r} \leq (\mathbb{E} X^p)^r.
\]

In the other case, we repeat the arguments used in the proof of Lemma 6. Suppose for definiteness that \( \gamma_1 \) is the largest number among all \( \gamma_i \)'s. Necessarily \( \gamma_1 > \frac{p+2}{2} \) and therefore \( \gamma_i < \frac{p+2}{2} \) for all \( i \geq 2 \). Since \( S_r < n \Rightarrow X_1 < n \), we similarly have

\[
\mathbb{E} \frac{X_1^{2\gamma_1} \cdots X_r^{2\gamma_r}}{\left(\frac{1}{n} S_r + 1\right)^{p+1}} 1_{(S_r < n)} \leq \mathbb{E} X_1^{2\gamma_1} \cdots X_r^{2\gamma_r} 1_{(S_r < n)}. \tag{42}
\]

To bound the last expectation, note that, if \( x = n \) is the point of continuity of \( F(x) \),

\[
\mathbb{E} X_1^{2\gamma_1} 1_{(X < n)} = -n^{2\gamma_1} (1 - F(n)) + 2 \gamma_1 \int_0^n x^{2\gamma_1-1} (1 - F(x)) \, dx \\
\leq 2 \gamma_1 \int_0^n x^{2\gamma_1-1-p-\alpha} e(x) \, dx.
\]

But since \( \gamma_1 \leq p - r + 3 \) (which follows from \( \gamma_1 + \gamma_2 + \cdots + \gamma_r = p + 2 \) and \( \gamma_i \geq 1 \)), we have

\[
\int_1^n x^{2\gamma_1-p-\alpha} e(x) \, dx \leq \int_1^n x^{p-2r-\alpha+5} e(x) \, dx.
\]

The last integral grows at the desired rate \( O(n^{p-r-a+4}) \) as the worst case, if and only if \( p - 2r - \alpha + 5 \leq p - r - \alpha + 3 \), that is, \( r \geq 2 \) (which is true). Thus,

\[
\mathbb{E} X_1^{2\gamma_1} 1_{(X < n)} = O(n^{p-r-a+4})
\]

In view of (42), this proves (41) for the part of the expectation restricted to the set \( S_r < n \), that is,

\[
\mathbb{E} \frac{X_1^{2\gamma_1} \cdots X_r^{2\gamma_r}}{\left(\frac{1}{n} S_r + 1\right)^{p+1}} 1_{(S_r < n)} = O(n^{p-r-a+4}). \tag{43}
\]

Here, the worst situation is attained in the case \( r = 2, \gamma_1 = p + 1, \gamma_2 = 1 \).

Turning to the expectation over the complementary set \( S_r \geq n \), introduce the events

\[\Omega_i = \left\{ X_i \geq \max_{j \neq i} X_j \right\}, \quad i = 1, \ldots, r.\]

On every such set, \( X_i \leq S_r \leq r X_i \). In particular, \( S_r \geq n \) implies \( X_i \geq n/r \). Hence, together with (43), (41) would follow from the inequality

\[
\mathbb{E} \frac{X_1^{2\gamma_1} \cdots X_r^{2\gamma_r}}{X_{\max}^{p+1}} 1_{(X_i \geq n) \cap \Omega_i} = O(n^{p-r-a+3}) \tag{44}
\]

with an arbitrary index \( 1 \leq i \leq r \).
Case 1. \( i \geq 2 \). If we fix any values \( X_1 = x_1 \) and \( X_i = x_i \), then the expectation with respect to \( X_j, j \neq i \), in (44) will yield a bounded quantity (since the \((p + 2)\)-moment is finite). Hence (44) is simplified to

\[
\mathbb{E} X_1^{2\gamma_1} X_i^{2\gamma_i-p-1} 1_{\{X_i \geq n\} \cap \{X_1 \geq x_1\}} = O(n^{-r+\alpha+3}).
\]  

(45)

Here, the expectation over \( X_1 \) may be estimated similarly to the previous step, by replacing \( n \) with \( x_i \). Recall that \( \gamma_1 > \frac{p+2}{2} \) and hence \( 2\gamma_1 \geq p + 3 \).

Case 1.1. \( 2\gamma_1 > p + \alpha \). Then we have

\[
\mathbb{E} X_1^{2\gamma_1} 1_{\{X_i \leq x_i\}} \leq 2\gamma_1 \int_0^{x_i} x^{2\gamma_1-1-p-\alpha} \epsilon(x) \, dx \leq C x_i^{2\gamma_1-p-\alpha}
\]

with some constant \( C > 0 \). Hence, up to a constant, the expectation in (44) is bounded by

\[
\mathbb{E} X_i^{2\gamma_i+2\gamma_1-2p-\alpha-1} 1_{\{X_i \geq n\}} = \int_n^{\infty} x^{2\gamma_i+2\gamma_1-2p-\alpha-1} \, dF(x)
\]

\[
= n^{2\gamma_i+2\gamma_1-2p-\alpha-1} (1 - F(n)) + c_i \int_n^{\infty} x^{2\gamma_i+2\gamma_1-2p-\alpha-2} (1 - F(x)) \, dx
\]

\[
= O(n^{2\gamma_i+2\gamma_1-3p-2\alpha-1}) + c_i \int_n^{\infty} x^{2\gamma_i+2\gamma_1-3p-2\alpha-2} \epsilon(x) \, dx
\]

\[
= O(n^{2\gamma_i+2\gamma_1-3p-2\alpha-1}).
\]

To obtain (45), it remains to check that \( 2\gamma_i + 2\gamma_1 - 3p - 2\alpha - 1 \leq -r - \alpha + 3 \). And indeed, since

\[
p = \gamma_i + \gamma_1 + \sum_{j \neq i, 1} \gamma_j \geq \gamma_i + \gamma_1 + (r - 2),
\]

the desired relation would follow from \( 2(p - (r - 2)) - 3p - 2\alpha - 1 \leq -r - \alpha + 3 \), that is, \( p + r \geq \alpha \) (which is true since \( \alpha \leq 4 \), while \( p, r \geq 2 \)).

Case 1.2. \( 2\gamma_1 \leq p + \alpha \). Then \( \mathbb{E} X_1^{2\gamma_1} 1_{\{X_i \leq x_i\}} \leq \mathbb{E} X^{p+\alpha} \) which is bounded in \( x_i \), and the expectation in (44) does not exceed up to a constant

\[
\mathbb{E} X_i^{2\gamma_i+2\gamma_1-p-1} 1_{\{X_i \geq n\}} = \int_n^{\infty} x^{2\gamma_i+2\gamma_1-p-1} \, dF(x)
\]

\[
= n^{2\gamma_i+2\gamma_1-p-1} (1 - F(n)) + c_i \int_n^{\infty} x^{2\gamma_i+2\gamma_1-p-2} (1 - F(x)) \, dx
\]

\[
= O(n^{2\gamma_i+2\gamma_1-2p-\alpha-1}) + c_i \int_n^{\infty} x^{2\gamma_i+2\gamma_1-2p-\alpha-2} \epsilon(x) \, dx = O(n^{2\gamma_i+2\gamma_1-2p-\alpha-1}).
\]

To obtain (45), it remains to check that

\[2\gamma_i + 2\gamma_1 - 2p - \alpha - 1 \leq -r - \alpha + 3.\]
And indeed, by (45), the desired relation would follow from

\[ 2 \gamma_1 p - \frac{1}{p} \gamma_1 \alpha r \leq 2 \gamma_1 p - \frac{1}{p} \gamma_1 \alpha + \frac{3}{2}, \]

that is, \( r \geq 0 \).

**Case 2.** \( i = 1 \). If we fix any value \( X_1 = x_1 \) in (44), the expectation with respect to \( X_j, j \neq 1 \), yields a bounded quantity. Hence (44) is simplified to

\[ \mathbb{E} X^2 \gamma_1 p - 1_{\{X \geq n\}} = O(n^{-r+\alpha+1}). \]

We have

\[ \mathbb{E} X^2 \gamma_1 p - 1_{\{X \geq n\}} = \int_n^\infty x^2 \gamma_1 p - 1 dF(x) \]

\[ = n^{2 \gamma_1 p - 1} (1 - F(n)) + (2 \gamma_1 p - 1) \int_n^\infty x^2 \gamma_1 p - 2 (1 - F(x)) dx \]

\[ = O(n^{2 \gamma_1 p - 2} p - 1) + \int_n^\infty x^2 \gamma_1 p - 2 - \frac{1}{\gamma_1} x \cdot \frac{1}{\gamma_2} dx = O(n^{2 \gamma_1 p - 2} p - 1). \]

It remains to see that \( 2 \gamma_1 p - \frac{1}{p} \gamma_1 \alpha - 1 \leq -r - \frac{1}{p} \gamma_1 \alpha + 3 \), that is, \( 2 \gamma_1 p - \frac{1}{p} \gamma_1 \alpha + 4 \). But this follows from \( p + 2 = \gamma_1 + \cdots + \gamma_r \geq \gamma_1 + (r - 1) \geq \frac{\gamma_1}{2} \).

**4 Proofs of main results**

**Proof of Theorem 1** Fix \( k \geq 3 \). In the following we omit \( k \) in notation when it is not necessary. So we write \( S_n = S_n(k), \lambda = \lambda(k), Z = Z_k, I = I(k) \). We say that a random variable \( V \) has a mixed Poisson distribution with mixing distribution \( F \) when, for every integer \( m \geq 0 \),

\[ \mathbb{P}(V = m) = \mathbb{E} \left( e^{-\Lambda} \frac{\Lambda^m}{m!} \right), \]

where \( \Lambda \) is a random variable with distribution \( F \).

Put \( \Lambda = \sum_{\alpha \in I} \mathbb{E} Y_{\alpha} \).

We have for any real function \( h : \{0, 1, 2, \ldots\} \to \mathbb{R} \)

\[ |\mathbb{E} h(S_n) - \mathbb{E} h(Z)| \leq \mathbb{E} |h(W_{\alpha} Y_{\alpha}) - \mathbb{E} h(W_{\alpha} Y_{\alpha})| + |\mathbb{E} h(V) - \mathbb{E} h(Z)|. \] (46)

For each \( \alpha \in I \), define \( B_{\alpha} = \{ \beta \in I : \alpha \text{ and } \beta \text{ have at least one edge in common} \} \). Put

\[ b_1 = \sum_{\alpha \in I} \sum_{\beta \in B_{\alpha}} p_{\alpha} p_{\beta}, \]

where \( p_{\alpha} = \mathbb{E} Y_{\alpha} \).

\[ b_2 = \sum_{\alpha \in I} \sum_{\alpha \neq \beta \in B_{\alpha}} p_{\alpha} p_{\beta}, \]
where $p_{\alpha \beta} = \mathbb{E}W_1, \ldots, W_n Y_\alpha Y_\beta$.

Note that, for any $\alpha \in I$ and $\beta \in I \setminus B_\alpha$, the cycles $\alpha$ and $\beta$ may have joint vertices but do not have any edge in common. Therefore, for such $\alpha$ and $\beta$, the random variable $Y_\alpha$ and $Y_\beta$ are conditionally independent given weights $W_1, \ldots, W_n$. Thus, by Theorem 1 in [2], proved with the Chen–Stein method, and relations (2) and (46), we get

$$\mathbb{E} \mathcal{L}_n = \mathcal{L}(Z) = \mathcal{L}(\mathbb{E}) \leq (b_1 + b_2) + [\mathbb{E} \Lambda - \lambda(k)],$$

where we write here and in the following that $A_n < B_n$ or $A_n > B_n$ when there exists a positive constant $c$ not depending on $n$ such that $A_n \leq cB_n$ or $A_n \geq cB_n$.

For random variables $b_1$ and $b_2$, we get, cf. (14), by the i.i.d. assumption and simple inequality for positive $c$ and $d$: $\log n$,

$$\mathbb{E}(b_1 + b_2) \leq \sum_{p=k+2}^{2k} \sum_{r=k}^{p-1} \frac{n(n-1) \ldots (n-r+1)}{n^p} \sum_{\gamma \in C(p, r)} \mathbb{E}\psi_\gamma(\gamma),$$

where

$$\psi_\gamma(\gamma) = W_{R1} \ldots \gamma W_{Rr} / (L_r + L_{n,r})^p$$

and

$$L_r = W_1 + \cdots + W_r, \quad L_{n,r} = W_{r+1} + \cdots + W_n.$$

For example, we have minimal value $p = k + 2$ and $r = k + 1$ for the cycles $\alpha = (1, 2, \ldots, k)$ and $\beta = (1, 2, \ldots, k-1, k+1)$. Then

$$\mathbb{E} p_{\alpha \beta} \leq \mathbb{E} W_1^2 W_2^2 \ldots W_{k-1}^2 W_k^2 / L_n^{k+2}.$$

We have maximal value $p = 2k$ and $r = k$ for the cycle $\alpha = (1, 2, \ldots, k)$. Then

$$\mathbb{E} p_{\alpha \alpha} \leq \mathbb{E} W_1^4 \ldots W_k^4 / L_n^{2k}.$$

Lemmas 4 and 6 and inequality (48) under condition (4) imply

$$\mathbb{E}(b_1 + b_2) = o \left( \log \frac{n}{\log n} \right).$$

Now we construct an upper bound for the last summand in (47).

It is clear that

$$\mathbb{E} \Lambda \leq \frac{1}{2k} \mathbb{E} \left( \frac{(W_1^2 + \cdots + W_n^2)^k}{L_n^k} \right).$$

On the other hand, note that for a positive $a$ and positive sequence $\{x_i\}, i = 1, 2, \ldots, k$, we have, see e.g. Lemma 8 in [19]

$$\frac{1}{a} \sum_{i=1}^{k} x_i \geq \frac{\sum_{i=1}^{k} x_i}{a^{k+1}}.$$
Therefore, by the i.i.d. assumption, we get
\[
\mathbb{E} \Lambda \geq \frac{1}{2k} \mathbb{E} \left( \frac{(W_1^2 + \cdots + W_n^2)^k}{L_n^k} \right) - c_1 \sum_{r=1}^{k-1} \frac{n(n-1) \cdots (n-r+1)}{n^k} \sum_{\gamma \in C(k,r)} \mathbb{E} \psi_n(\gamma)
\]
\[
- \frac{c_2}{n} \sum_{\gamma \in C(k+1,k)} \mathbb{E} \left( \frac{W_1^{2\gamma_1} \cdots W_1^{2\gamma_r}}{(L_n/n)^{k+1}} \right),
\]
where \(c_1\) and \(c_2\) do not depend on \(n\).

Combining Lemmas 4 and 6 and relations (7), (47), (49), (50) and (51), we finish the proof of Theorem 1.

**Proof of Theorem 2** We split the proof of the Theorem into several steps. Without loss of generality, let \(\mathbb{E} X = 1\).

**Necessity.** By Lemma 3, for the convergence \(\mathbb{E} T^p_n \to (\mathbb{E} X^2)^p\), it is necessary that all summands in (14) with \(r < p\) should be vanishing at infinity. In particular, for the shortest tuple \(\gamma\) with \(r = 1\) as in Lemma 2, it should be required that \(n^{1-p} \mathbb{E} \xi_n(\gamma) \to 0\) as \(n \to \infty\). Hence, from the inequality (15) it follows that
\[
\mathbb{E} X^p 1_{\{X \geq n\}} = o(1/n).
\]
This relation may be simplified in terms of the tails of the distribution of \(X\). Indeed, \(\mathbb{E} X^p 1_{\{X \geq n\}} \geq n^p \mathbb{P}\{X \geq n\}\), so that the property (16) is necessary for the convergence \(\mathbb{E} T^p_n \to (\mathbb{E} X^2)^p\).

**Sufficiency and rate of convergence.** First note that the condition (16) ensures that the moment \(\mathbb{E} X^p\) is finite. For the convergence part of Theorem 2 we apply Lemmas 4-6, which imply that \(n^{1-p} \mathbb{E} \xi_n(\gamma) = o(1/n^p)\) for any collection \(\gamma = (\gamma_1, \ldots, \gamma_r)\) with \(r > p\). It remains to take into account Lemma 3 about the longest tuple \(\tilde{\gamma} = (1, \ldots, 1)\) of length \(r = p\) and to recall the representation (14).

Turning to the rate of convergence, first note that by Lemma 4 and 6 for any \(\gamma \in C(p,r)\) with \(2 \leq r \leq p-1\),
\[
\frac{n(n-1) \cdots (n-r+1)}{n^p} \mathbb{E} \xi_n(\gamma) = o\left( \frac{\log n}{n} \right)
\]
(52)
For the shortest tuple \(\gamma = (p)\) with \(r = 1\), we apply Lemma 5 with \(q = p + \frac{1}{2}\) and thus assume that \(\mathbb{P}\{X \geq x\} = O(x^{-p-\frac{1}{2}})\). Together with Lemma 1, this gives
\[
\frac{n}{n^p} \mathbb{E} \xi_n(\gamma) = O\left( \frac{1}{\sqrt{n}} \right),
\]
(53)
Note that with this tail hypothesis, necessarily \(\mathbb{E} X^\beta < \infty\) for any \(\beta < p + \frac{1}{2}\). Since \(p \geq 2\), we have that the 3-rd moment \(\mathbb{E} X^3\) is finite. Applying both (52) and (53) in the representation (14) and using (20), we thus obtain that
\[
\mathbb{E} T^p_n = \mathbb{E} \xi_n 1_{B_{n,p}} + O(1/\sqrt{n}),
\]
(54)
with $\xi_n$ defined in \eqref{eq:xi_n}.

It remains to study an asymptotic behavior of the last expectation in \eqref{eq:54}. Note that $\frac{1}{n} S_n \geq \frac{1}{n} S_{n,p} \geq \frac{1}{2}$ on the set $B_{n,p}$ as long as $n \geq 2p$. Applying the Taylor formula, we use an elementary inequality $|x^{p} - 1| \leq p |x - 1|$ for $x \geq \frac{1}{2}$. In particular, on the set $B_{n,p}$ one has $\left| \left( \frac{1}{n} S_n \right)^{-p} - 1 \right| \leq p^p |S_n - 1|$. This gives

$$|\xi_n - X_1^2 \ldots X_p^2| 1_{B_{n,p}} \leq p 2^{p+1} X_1^2 \ldots X_p^2 \left| 1 - \frac{1}{n} S_p - \frac{1}{n} S_{n,p} \right| + \frac{p 2^{p+1}}{n} X_1^2 \ldots X_p^2 S_{n,p},$$

so, taking the expected values,

$$\mathbb{E}|\xi_n - (\mathbb{E}X_1^2 \ldots X_p^2)| 1_{B_{n,p}} \leq p 2^{p+1} (\mathbb{E}X_1^2)^p \mathbb{E}\left| 1 - \frac{1}{n} S_{n,p} \right| + \frac{p 2^{p+1}}{n} (\mathbb{E}X_1^2)^{p-1} \mathbb{E}X_3.$$

In view of \eqref{eq:17},

$$\mathbb{E}X_1^2 \ldots X_p^2 1_{B_{n,p}} = \mathbb{E}X_1^2 \ldots X_p^2 + e^{-cn} = (\mathbb{E}X_1^2)^p + o(e^{-cn}),$$

for some constant $c > 0$. Recalling \eqref{eq:20}, we thus get that

$$\mathbb{E}|\xi_n - (\mathbb{E}X_1^2)^p| \leq p 2^{p+1} (\mathbb{E}X_1^2)^p \mathbb{E}\left| 1 - \frac{1}{n} S_{n,p} \right| + \frac{p 2^{p+1}}{n} (\mathbb{E}X_1^2)^{p-1} \mathbb{E}X_3 + o(e^{-cn}).$$

Finally

$$\mathbb{E}\left| \frac{1}{n} S_{n,p} - 1 \right| = \frac{1}{n} \mathbb{E}|S_{n,p} - n| \leq \frac{1}{n} \mathbb{E}|S_{n,p} - (n - p)| + \frac{p}{n} \leq \frac{1}{n} \sqrt{\text{Var}(S_{n,p})} + \frac{p}{n} \leq \frac{1}{\sqrt{n}} \sqrt{\mathbb{E}X_2^2} + \frac{p}{n}.$$
Rate of convergence to the Poisson law of the numbers of cycles in GRG

\[ c \mathbb{E} R_n \leq \frac{1}{n^{\alpha - 3}} + \frac{\log n}{n} \mathbb{E} M_n^2. \quad (55) \]

The last expectation in (55) may also be estimated in a polynomial way. Namely, since for any \( q \geq 2 \), one has \( M_n^2 \leq (X_1^q + \cdots + X_n^q)^{2/q} \), we get, by Jensen’s inequality,

\[ \mathbb{E} M_n^2 \leq (\mathbb{E} X_1^q + \cdots + \mathbb{E} X_n^q)^{2/q} = n^{2/q} (\mathbb{E} X^q)^{2/q}. \]

Therefore, choosing \( 2 < q < p + \alpha \) to be sufficiently close to \( p + \alpha \), and using \( \alpha = 7/2 \), from (55) we obtain (9). When \( \mathbb{E} X^{p+4} \) is finite, we get (10).

At last, to prove (11), note that the finiteness of the exponential moment of \( X \) is actually equivalent to the family of moment bounds \( \mathbb{E} X^q \leq C q \) for \( q \geq 1 \), which for \( q \geq 2 \) give

\[ \mathbb{E} M_n^2 \leq \mathbb{E} (X_1^q + \cdots + X_n^q)^{2/q} \leq (\mathbb{E} X_1^q + \cdots + \mathbb{E} X_n^q)^{2/q} \leq (cq)^2 n^{2/q}. \]

Choosing here \( q \) to be of order \( \log n \), we arrive at \( \mathbb{E} M_n^2 \leq C (\log n)^2 \) with a constant \( C \) independent of \( n \). Applying this bound in (55) with \( \alpha = 4 \), we then obtain the much better rate as in (11). \( \square \)
