INTRODUCTION

Bronchial asthma is a chronic respiratory disease characterised by varying degrees of chronic inflammation of the airways and airway remodelling.\(^1,2\) The pathological changes of airway remodelling mainly include airway epithelial damage, smooth muscle cell hypertrophy and so on.\(^3\) It has been found that transforming growth factor beta (TGF-\(\beta\))/Smad3 signalling pathway is one of the important signalling mechanisms leading to the formation of asthmatic airway remodelling.\(^4,5\) TGF-\(\beta\) is considered the main regulator of airway remodelling in asthma, directly affecting the deposition of collagen in the airway wall and promoting the formation of fibrosis.\(^6\) The Smads protein is an important member of the TGF-\(\beta\) signal transduction system, and Smad3 may be the signal transduction molecule that plays a leading role in the TGF-\(\beta\) signal transduction pathway.\(^7\) Inhaled corticosteroids, which can reduce chronic inflammation of the airways, are currently the most effective treatment for bronchial asthma. Dexamethasone is a commonly used glucocorticoid that not only improves asthmatic symptoms, but also reduces airway inflammation. There are studies available where effect of dexamethasone on the different modulator of respiratory airways have been demonstrated.\(^8\) However, whether dexamethasone plays a therapeutic role by regulating TGF-\(\beta\)/Smad3 signalling pathway is unclear.

The objective of this study was to investigate the effect of dexamethasone on the TGF-\(\beta\)/Smad3 signalling pathway in the airway remodelling model of rats with bronchial asthma, in order to provide reference for the treatment of bronchial asthma.

METHODOLOGY

This study was conducted at the Department of Pathology, The First Hospital of Wuhan, Hubei Province, China, from February 2017 to April 2018, after approval by the Committee on Animal Research and Ethics. Thirty healthy male SPF Sprague-Dawley rats were randomly divided into the control group, the model group, and the dexamethasone group by random number table, with 10 rats in each group. On the 1st and 8th day, 1 mL of ovalbumin (OVA) (1 mg) + Al (OH)\(_3\) (100 mg) saline solution was intraperitoneally injected for sensitisation, and the rats were placed in a semi-closed container.
Ultrasonic fog was started on the 15th day to excite the rats with 1% OVA atomisation, 30 min each time, once every other day for 8 weeks. When the typical episodes of asthma such as irritability, cough, shortness of breath, rapid breathing and decreased activity were observed, the bronchial asthma model was successfully constructed. The excitation stage of the dexamethasone group was the same as that of the model group. In the excitation phase, 0.5 mg/kg dexamethasone was intraperitoneally injected half an hour before the excitation, and the inhalation excitation was also carried out in a closed container with 1% OVA saline. In the sensitisation and excitation phases of the control group, the OVA/Al(OH)$_3$ mixture or the 1% OVA atomisation solution was replaced by normal saline.

Each group was sacrificed within 24 hours after the last excitation, and the thoracic cavity was opened immediately to expose the lung tissue. The trachea was opened and intubated with a 5.5 scalp needle to rapidly separate the lung tissue, and the lung tissue was quickly placed in liquid nitrogen for storage.

Three small bronchioles with intact structures in the left lung tissue sections of each rat were selected, and the bronchial basement membrane perimeter (Pbm), the bronchial wall area (Wat), the inner wall area (Wai), and other airway remodelling indices were measured by Image-pro Plus 6.0 pathological image analysis software. Wat, Wai, and Wam were normalised with Pbm, and Wat/Pbm, Wai / Pbm, Wam / Pbm respectively indicating the thickness of each layer of the corresponding wall.

The mRNA levels of TGF-$
\beta$1 and Smad3 in lung tissue of each group were detected by RT-PCR. Appropriate amount of right lung tissue was grounded under liquid nitrogen. RNA was extracted by adding RNA extraction reagent trizol, and the instructions were carried out in strict accordance with the kit instructions. The primer sequences of GAPDH, TGF-$
\beta$1 and Smad3 are shown in Table I. The RT-PCR reaction conditions were as follows: cDNA synthesis and pre-denaturation at 40°C for 10 min, 94°C for 2 min, PCR amplification at 94°C for 15 s, 58°C for 30 s, 72°C for 45 s, 40 cycles, and finally extension at 72°C for 10 min. Relative fluorescent quantitative PCR was used to detect the expression level. Bio-Rad CFX96 real-time quantitative PCR system software automatically generated the cycle value (Ct), and the relative quantification of the target gene was normalised to calculate $\Delta \Delta$Ct. The mRNA levels at TGF-$
\beta$1, Smad3 were calculated using the 2$^{-\Delta \Delta \text{Ct}}$ relative quantification method.

Western blot was used to detect the expression of TGF-$
\beta$1 and Smad3 protein in lung tissue. Appropriate amount of right lung tissue was taken to be washed twice with PBS. Radio-immunoprecipitation assay (RIPA) Lysis Buffer was added and homogenised at low temperature, which was then centrifuged at 12000 xg for 10 min at 4°C. Supernatant was taken and protein was quantified by BCA method to make the protein sample. The sample was loaded and SDS was carried out. After PAGE electrophoresis, the electrophoresis gel was immersed in the transfer membrane for 5 min, and proteins were blotted on the membrane by semidy method, and blocked with PBST containing 5% BSA for 1 hour at room temperature. Primary antibodies (TGF-$
\beta$1, Smad3 and $\beta$-actin) were incubated overnight at 4°C. The next day, the membrane was washed with TBST, and horseradish peroxidase-labelled goat anti-rabbit IgG was added for 2 hours at room temperature. After membrane washing, ECL chemiluminescence solution was added and placed in the gel imaging system to be observed and photographed. The protein gray value analysis was performed by Image J software, and the relative expression of TGF-$
\beta$1 and Smad3 protein was expressed by the ratio of the target band gray scale to the $\beta$-actin gray scale of the internal reference strip.

Data was analysed in SPSS version 21. Mean value±SD was calculated for measurement data. Multiple sample averages were compared using single factor analysis of variance. The p-values less than 0.05 were regarded as significant.

**RESULTS**

There were significant differences in Wat/Pbm, Wai/Pbm, and Wam/Pbm between the control group, the model group and the dexamethasone group (all p<0.001). Wat/Pbm, Wai/Pbm, and Wam/Pbm in the model group.

Table I: Primer sequence.

| Gene     | Upstream primer                | Downstream primer               |
|----------|--------------------------------|--------------------------------|
| GAPDH    | 5'–ACTCAGAAGACTGTGGATGG-3'     | 5'–GTTGCGTGTTGAGTGAGTCACAGG-3' |
| TGF-$
\beta$1 | 5'–GGAGACATGAGAGCTGCAAC-3'    | 5'–CCAGCAGCATGTGAAGATC-3'      |
| Smad3    | 5'–TGTCACATGAGACGTCAAGCA-3'   | 5'–TCGTACAGCATGTGAAGAT-3'      |

Table II: Comparison of airway remodelling indices in each group.

| Parameters | Control group (Number of bronchus measured = 30) | Model group (Number of bronchus measured = 30) | Dexamethasone group (Number of bronchus measured = 30) | p-value |
|------------|---------------------------------------------------|-------------------------------------------------|-----------------------------------------------------|---------|
| Wat/Pbm ($\mu m^2 \mu m^{-1}$) | 50.73 ±3.20                                      | 73.06 ±4.89                                     | 61.22 ±3.70                                          | <0.001  |
| Wai/Pbm ($\mu m^2 \mu m^{-1}$) | 41.92 ±3.84                                      | 65.87 ±2.59                                     | 52.41 ±3.02                                          | <0.001  |
| Wam/Pbm ($\mu m^2 \mu m^{-1}$) | 9.17 ±1.34                                       | 25.35 ±1.99                                     | 17.08 ±2.06                                          | <0.001  |
Related studies have shown that TGF-β1 is significantly increased in airway epithelium and submucosa of asthmatic patients, and its expression is positively correlated with airway basement epithelium and submucosa of asthmatic patients, and its expression is positively correlated with airway basement

membrane thickness, number of fibroblasts, and severity of asthma attacks. Ojiaku et al. revealed a potential link between airway injury-repair responses and bronchial hyperreactivity in asthma, and define TGF-β1 signalling as a potential target to reduce AHR in asthma. Studies have also shown that TGF-β1 is significantly increased in airway epithelium and submucosa of asthmatic patients, and its expression is positively correlated with airway basement membrane thickness, number of fibroblasts, and severity of asthma attacks. Smads family of proteins is by far the only proven substrate acted by the TGF-β1 receptor.

**DISCUSSION**

Pathological changes in airway wall and airway smooth muscle layer thickening are important pathological features in asthmatic airway remodelling. Studies have found that in asthmatic airway remodelling, there is an increased number of airway smooth muscle cells (ASMCs) or cell hypertrophy, and the smooth muscle layer is significantly thickened. Related studies have shown that the bronchial basement membrane perimeter remains relatively unchanged in the airway under different systolic and diastolic states. Accordingly, the bronchial basement membrane perimeter was measured to normalise the total wall area, the inner wall area, and the smooth muscle area to eliminate the effect of different airway contractions on the measurement results. This study found that the intrapulmonary bronchial Watt/Pbm, Wai/Pbm, Wam/Pbm in inhaled OVA-sensitised asthmatic rat models increased significantly compared with those in the control group, which is consistent with other reports. Wat /Pbm, Wai /Pbm, and Wam /Pbm can be used to measure the extent of airway remodelling.

At present, the role of inhaled corticosteroids in asthma still remains controversial. Studies have found that glucocorticoid dexamethasone can inhibit ASMC proliferation. Some scholars have found that dexamethasone can alleviate the symptoms of allergic asthma rats. This study showed that the ratio of Watt/Pbm, Wai/Pbm, and Wam/Pbm in the model group was significantly lower than that in the dexamethasone group. It suggested that dexamethasone can inhibit the increase of airway wall and smooth muscle thickness, posing a positive effect on improving airway remodelling. This conclusion is basically consistent with previous research reports.

Airway smooth muscle of asthmatic patients secretes a large amount of TGF-β1, which in turn will promote hypertrophy of smooth muscle cells and goblet cells, promote collagen and fibronectin synthesis and deposit in extracellular matrix, thereby causing airway lumen narrowing and irreversible lung function changes. Ojiaku et al. revealed a potential link between airway injury-repair responses and bronchial hyperreactivity in asthma, and define TGF-β1 signalling as a potential target to reduce AHR in asthma. Studies have also shown that TGF-β1 is significantly increased in airway epithelium and submucosa of asthmatic patients, and its expression is positively correlated with airway basement membrane thickness, number of fibroblasts, and severity of asthma attacks. Smads family of proteins is by far the only proven substrate acted by the TGF-β1 receptor.

**Discussion**

Table III: Comparison of relative expression levels of TGF-β1 and Smad3 mRNA in lung tissue of rats in each group.

| Parameters     | Control group (Number of rats = 10) | Model group (Number of rats = 10) | Dexamethasone group (Number of rats = 10) | p-value |
|---------------|------------------------------------|----------------------------------|------------------------------------------|---------|
| TGF-β1 mRNA   | 0.92 ±0.57                         | 1.98 ±0.45                       | 1.21 ±0.17                               | <0.001  |
| Smad3 mRNA    | 0.51 ±0.23                         | 1.45 ±0.39                       | 0.76 ±0.30                               | <0.001  |

Table IV: Comparison of relative expression levels of TGF-β1 and Smad3 protein in lung tissue of rats in each group.

| Parameters     | Control group (Number of rats = 10) | Model group (Number of rats = 10) | Dexamethasone group (Number of rats = 10) | p-value |
|---------------|------------------------------------|----------------------------------|------------------------------------------|---------|
| TGF-β1 protein| 0.84 ±0.18                         | 1.75 ±0.38                       | 0.96 ±0.26                               | <0.001  |
| Smad3 protein  | 0.45 ±0.14                         | 1.37 ±0.31                       | 0.64 ±0.15                               | <0.001  |

Figure 1: Results of Western blot analysis of TGF-β1 and Smad3 protein expression:
1: Control group, 2: Model group, 3: Dexamethasone group.
Smad3 is a receptor-regulated Smad protein. When phosphorylated with Smad2 by a TGF-β1 type I receptor, it forms a heteromultimer with Smad4 and is transferred into the nucleus to bind to DNA to activate DNA transcription, regulating the expression of the target protein. Lund et al. found that the development of atopic asthma in children with early rhinovirus-induced wheezing was associated with DNA methylation changes at several genomic sites in chromosomal regions previously linked to asthma; and the strongest changes in atopic asthma were detected in the promoter region of Smad3 gene at chr 15q22.33 and introns of DDO/METTL24 genes at 6q21.19 Le et al. suggested that Smad3 signalling is required for allergen-induced airway remodelling, as well as allergen-induced accumulation of myofibroblasts in the airway.20 Studies indicate that there is a possible pathway of mouse pulmonary fibrosis model through TGF-β1/Smad3 pathway.21 The results of this experiment show that dexamethasone can effectively reduce the expression of TGF-β1, Smad3 mRNA and protein in the lung tissue of asthmatic rats, as well as delay airway remodeling.

**CONCLUSION**

Dexamethasone may antagonize airway remodelling by regulating TGF-β1/Smad3 signalling pathway, likely to play a role in the treatment of bronchial asthma.
