**ABSTRACT**

Cyanobacteria are known for their potential for antibacterial activity against a variety of pathogens, which are of medicinal importance in drug development. In addition, Cyanobacterial species produce various secondary metabolites that are used as dye and pigmentation and food additives. Cyanobacteria *Dolichospermum affine* (Lemmermann) Wacklin, L. Hoffmann & Komárek was isolated from freshwater resources and its antimicrobial effect was studied. Chloroform, methanol and water extracts of *D. affine* were tested to investigate their efficiency against five pathogenic bacterial strains [*Pseudomonas aeruginosa* (ATCC 27853), *Shigella dysenteriae* (ATCC 11835), *Escherichia coli* (ATCC 25924), *Staphylococcus aureus* (ATCC 29213) and *Bacillus subtilis* (ATCC 6633)]. The antimicrobial test was determined using the disk diffusion method. The antimicrobial activities of *D. affine* extracts were measured using the diameter of the inhibition zone (DIZ) of the pathogen microorganisms. The results showed that *B. subtilis* and *E. coli* were more sensitive, while *S. aureus* and *P. aeruginosa* showed more intermediate results. The highest antimicrobial activity was measured against *E. coli* (DIZ=13.9±0.05 mm - methanol), followed by *B. subtilis* (DIZ=13.6±0.05 mm - methanol). The lowest antibacterial effect of *D. affine* extracts was observed against *P. aeruginosa* (DIZ=11.7±0.02 mm - chloroform) and *S. aureus* (DIZ=12.2±0.03 mm - chloroform). The Gram-negative bacteria *S. dysenteria* exhibited no zone of inhibition. The aqueous extract showed poor activities against the tested pathogenic bacteria. Therefore, this study revealed that *D. affine* extracts would be a promising natural resource for new antibiotics and further research would be needed.

**Keywords:** Cyanobacteria, *Dolichospermum affine*, antibacterial activity, zone of inhibition

**INTRODUCTION**

Algae are organisms that live in both aquatic and terrestrial environments and in a wide variety of habitats, there are also numerous species and they are the primary producers of ecosystems. The components produced by algae are antioxidants and pigments (including fucoxanthine, carotenoids, lutein, b-carotene, astaxanthin and phycobiliproteins), long chain polyunsaturated fatty acids (LC-PUFA) and proteins (essential amino acids methionine, threonine and tryptophan). These secondary metabolites have wide applications in food, feed, agricultural and pharmaceutical industries (Gouveia, 2014; Walker, Purton, & Becker, 2005; Brennan & O’wened, 2010). Today, the use of biomedical and pharmacological potentials of secondary algal metabolites in algal biotechnology is a relatively new trend (Lorenz & Cseyewski, 2000; Walker et al., 2005). Naturally active compounds found in algal biomass have different biological properties such as cytotoxic, antibiotic, antioxidant, antifungal, anti-inflammatory and antihelminthic (Pulz & Gross, 2004; Gouveia, Batista, Sousa, Raymundo, & Bandarra, 2008; Plaza, Santoyo, & Jaime, 2010; Patil, Patil, Mahajan, & Mahajan, 2011). Algae are also used as biomolecule and biomass sources in fish farming, which can increase the nutritional value of foods or provide...
additional health benefits (Mulbry, Konrad, & Buyer, 2008). They are also used in bioremediation applications and as a biofertilizer because of their nitrogen fixation (Demir, 2011). Today, the most important future use of biomass obtained from algae is thought to be production of biofuels as a renewable energy source (Converti, Casazza, Ortiz, Perego, & Borghi, 2009; Demirbas, 2010).

Cyanobacteria were the first photosynthetic organisms living in the seas 3.5 billion years ago, capable of photosynthesis and having prokaryotic cell structure. Due to their physiological flexibility and long evolutionary backgrounds, they are found in a wide variety of ecosystems (Weis & Pang, 2010). They show distinct morphological differences for species as well as single-celled or filamentous forms. The cell size of cyanobacteria is in the range of 0.5-1 µm to 40 µm. It is capable of synthesizing chlorophyll-a and at least one phycobilin as a pigment. Phycocyanin, which belongs to the phycobilin group, is blue in color and is the cause of the blue-green color of most cyanobacteria with chlorophyll-a (Madigan, Martinko, Stahl, & Clark, 2012). An important feature of some species of cyanobacteria is the ability to fix atmospheric nitrogen (N₂). Cyanobacteria species that fix nitrogen are generally in filament form and make N₂ fixation by a small number of specialized cells called “Heterocyst” (Whitton, 2000).

In recent years, interest in biologically active substances from cyanobacteria has increased. Various studies have demonstrated that cyanobacterial secondary metabolites have hypcholesterolemic properties, enzyme inhibitor and other pharmacological effects (Abobaker & Elsalhin, 2019). Various types of cyanobacteria are known to produce intracellular and extracellular metabolites with antibacterial and antifungal properties (Kreitlow, Mundt, & Lindequist, 1999). These natural products are used in the production of raw pharmaceutical materials and as structural models in the synthetic molecules (Gault & Marler, 2009).

Bacterial infections cause major diseases worldwide, leading to high mortality rates in humans and animals. Antimicrobial agents are widely used in the treatment of bacterial infections, but bacteria can become resistant to existing drugs. For this reason, researchers have begun to search for natural compounds in order to discover new antibacterial compounds (Taskin, Ozturk, Taskin, & Kurt, 2007). Cyanobacteria are seen as promising biological resources in this field. Previous studies on antimicrobials obtained from natural sources have focused on Spirulina platensis, Chroococcus sp., Oscillatoria sp., Synechocystis aquatilis, Anabaena sp., Oscillatoria limosa, Pseudoanabaena limnetica, Phormidium tenue and Spirulina platina species (Özdemir, Karabay, Dalay, & Pazarbaş, 2004; Demiriz, Çökmüş, & Pabuçcu, 2011). As can be seen above, the antimicrobial properties of cyanobacteria have been studied in different species, but a study on Dolichospermum affine has not been found in the literature. This research investigated the antibacterial activity of cyanobacteria D. affine extracts against five selected pathogenic bacteria.

**MATERIALS AND METHODS**

**Sample isolation**

In our previous studies, D. affine was isolated in samples collected from various freshwater resources in Ankara, Turkey. The one-cell growth technique was used for the isolation of strains (Parvin, Zannat, & Habib, 2007). Taxonomic identification of the isolate was based on morphological features and species keys (Prescott 1973; John, Witton, & Brook, 2002; Guiry & Guiry 2018). The subcultures were prepared by putting 30 ml BG-11 nutrient media into 50 ml Erlemeyer flasks and adding approximately 20% culture depending upon the intensity of cells (Hur, Bae, Yoon, & Jo, 2015). BG-11 medium contained (in g/L) NaNO₃, 1.5; K₂HPO₄, 0.04; MgSO₄·7H₂O, 0.075; CaCl₂·2H₂O, 0.036; citric acid, 0.006; ferric ammonium citrate, 0.006; EDTA, 0.001; Na₂CO₃, 0.02. This medium was amended with 1 ml trace solution of composition (in g/L) H₃BO₃, 2.86; MnCl₂·1.81; ZnSO₄·7H₂O, 0.222; Na₂MoO₄·2H₂O, 0.39; CuSO₄·5H₂O, 0.079; and Co(NO₃)₂·6H₂O, 0.0494 (UTEX, 2016). All the chemicals were obtained from Merck, Germany. The pH was adjusted to 6.8 (Andersen & Kawachi, 2005). Those containing 30 ml cultures were incubated at 25°C under fluorescent lamps at a photon flux density of 50 µmol photons m⁻² s⁻¹ with a photocycle of light for 16 hours and darkness for 8 hours (Guillard, 2005).

**Cyanobacteria culture**

*D. affine* was cultivated in BG-11 culture medium and the experiments were carried out in 500 ml Erlemeyer flasks containing 200 ml of medium and 50 ml suspended culture at room temperature. Light was provided by cool-white fluorescent lamps at photon flux density of 50 µmol photons m⁻² s⁻¹ with a photocycle of a light for 16 hours and darkness for 8 hours for 14 days (Guillard, 2005). After culturing, the cells of *D. affine* were centrifuged at 5000 rpm for 20 min (Nüve NF 200), the supernatant was discarded, and the remaining pellets were then used to test the effect of the algal extracts on some bacteria strains.

**Preparation of algal extracts**

Approximately one gram of dried powder of *D. affine* pellets was extracted with chloroform, methanol and water (10 ml) and shaking overnight for complete extraction. The extract was filtered and the filtrate was concentrated under reduced pressure at 37-40°C and stored in a refrigerator till further use. The concentration was adjusted to 1mg/ml using the same solvent used for extraction was assayed for antibacterial activity (Malathi, Ramesh Babu, Mounika, Snehala, & Digamber Rao, 2014; Deshmukh & Puranik, 2012).

**Test microorganisms**

In vitro antibacterial studies were carried out against the 5 human pathogen bacteria as shown in Table 1. Nutrient Broth was used to grow these cultures and incubated at 30±1°C overnight.

| Human Pathogen Bacteria       | Code        | Type        |
|-------------------------------|-------------|-------------|
| Pseudomonas aeruginosa        | ATCC 27853  | gm negative |
| Shigella dysenteria           | ATCC 11835  | gm negative |
| Escherichia coli              | ATCC 25924  | gm negative |
| Staphylococcus aureus         | ATCC 29213  | gm positive |
| Bacillus subtilis             | ATCC 6633   | gm positive |

**Table 1. Test organisms.**
Antibacterial assay

The antibacterial activity test was done using the agar well diffusion method (Perez, Pauli, & Bazerque, 1990). 0.1 ml of diluted inoculum (10^6 CFU ml^-1) of the bacterial strains were swabbed on agar plates, and 5.0 mm size diameter wells on agar plates were made with a sterile cork borer (5.0 mm). Using a micropipette, 100 μl of algal extract was added to the wells made on each plate. The plates were allowed to incubate at 37±2°C for 24 to 48 h. Antibacterial activity was assessed by measuring the zone of inhibitions (mm) against the bacterial strains. Negative controls were prepared using the same solvents employed to dissolve the obtaining extracts. Gentamycin (10 μg) and Ampicillin (10 μg) antibiotic discs were used as a positive reference standard to determine the sensitivity of one strain from each bacterial species. The tests were performed in triplicate. The following antimicrobial index formula was used to compare the antimicrobial activity of the sample with the activity of the standard (Malathi et al., 2014):

\[ \text{Antimicrobial Index} = \frac{\text{Extract inhibition zone}}{\text{Antibiotic inhibition zone}} \times 100 \]

Statistical analysis

The results were presented as mean values ± standard deviation. The standard deviations were calculated using Microsoft Excel.

RESULTS AND DISCUSSION

*Dolichospermum affine* (Lemmermann) Wacklin, L. Hoffmann & Komárek is a Cyanobacteria which belongs to the family Aphani-zomenonaceae of class Cyanophyceae and this is a freshwater species. Fig. 1 presents the taxonomic classification (left) of *D. affine* (Guiry & Guiry, 2018) and its appearance under a microscope (right).

Cyanobacteria produce different bioactive compounds with antibacterial, antifungal, antiviral, and anti-inflammatory properties of industrial, therapeutic and agricultural importance (Sethubathi & Prabu, 2010). The discovery that extracts from cyanobacteria have antimicrobial activity has shown that Cyanobacteria can be an important source in obtaining new bioactive compounds in the pharmaceutical field (Thajuuddin & Subramanian, 2005). In the study of Sethubati & Prabu (2010) with the extracts they obtained from Oscillatoria sp., Phormidium sp. and Lyngbya majuscula; Oscillatoria sp. showed the highest antibacterial activity and L. majuscula the lowest. In the study of Abd El-Aty et al., (2014) with Anabaena sphaerica and Oscillatoria agardhii, they found that these species showed antibacterial activity against some Gram-negative and Gram-positive bacteria. In this study, the results of antibacterial activity of the *D. affine* against two Gram-positive and three Gram-negative bacterial strains are shown in (Table 2). It is obvious that the diameter of the inhibition zone (DIZ) depends on the type of algal species, the kind of solvent used and the tested pathogenic microorganisms. In the present study, extracts of *D. affine* were used with three different solvents, namely methanol, chloroform and aqueous extracts. The mean values of three replicates of the DIZ (in millimeters) around each well with different extracts are also given in Table 2. *D. affine* extracts confirmed antibacterial activities against four tested pathogenic bacteria out of five pathogenic bacterial strains. Methanol extracts exhibited better antibacterial activities than chloroform extracts. According to DIZ results, *Bacillus subtilis* and *Escherichia coli* were more sensitive, while *Staphylococcus aureus* and *Pseudomonas aeruginosa* showed more intermediate results. The highest antimicrobial activity was measured against *E. coli* [DIZ=13.9±0.05 mm (methanol) and DIZ=13.8±0.01 mm (chloroform)], followed by *B. subtilis* [DIZ=13.6±0.05 mm (methanol) and DIZ=13.5±0.06 mm (chloroform)] (Fig. 2). *D. affine*’s chloroform extract showed the lowest antibacterial effect in both *P. aeruginosa* (DIZ=11.7±0.02 mm) and *S. aureus* (DIZ=12.2±0.03 mm). The Gram-negative bacteria *S. dysenteriae* exhibited no zone of inhibition. The aqueous extract showed poor activities against the tested pathogenic bacteria. Chloroform, Methanol, Distilled water negative control also showed no inhibitory effect, while the positive control (Gentamicin and Ampicillin) showed inhibition diameters ranging from 13.0 to 27.0 mm and 13.0 to 26.0 mm respectively.

Halder (2015) tested the antibacterial effects of *Anabaena variabilis* extracts in different solvents against the eight pathogenic bacterial strains out of which three are Gram positive (*Bacillus subtilis*, *Micrococcus luteus* and *Staphylococcus aureus*) and five are Gram negative bacteria (*Escherichia coli*, *Pseudomonas aeruginosa*, *Shigella dysenteriae*, *Shigella flexneri* and *Vibrio cholerae*) using the agar well diffusion method. It was found that the results obtained from the same solvent and bacteria used in the study by Halder (2015) were similar to the results in this study. In the study conducted by Abobaker & Elsalhin (2019), extracts of *Anabaena circinalis* in different concentrations (25, 50, 75 and 100%) were tested to determine the efficacy against four bacterial strains (*Achromobacter xylosoxidans*, *Staphylococcus aureus*, *Escherichia coli*, *Shigella dysenteriae*). Results showed that the highest level of antimicrobial activity was recorded against *S. dysenteriae* at
However, in this study, the extracts in different solvents of *D. affine* against *S. dysenteriae* did not cause any antibacterial effect. It is thought that this may be caused by the species used in the studies and the different solvents.

Antibiotic-resistant bacterial species are serious threats to animal and human health and cause serious damage. Clinical studies on the resistance mechanism of bacteria have enabled the identification of clinical uses of all antimicrobial agents (Helms, Vastrup, Gerner-Smidt, & Molbak, 2002). Due to increased bacterial resistance to commercial standards and reserve antibiotics, it is important to search for new active substances with antibacterial activity (Abobaker & Elsalhin, 2019). In this context, Cyanobacteria have started to be seen as promising sources in the production of antimicrobial substances due to their biologically active substances. Extracts of different Cyanobacteria species obtained by different solvents exhibited different degrees of antimicrobial activity on pathogenic microorganisms and have been studied by different researchers. In the study conducted by Tiwari & Sharma (2013), cyanobacterial extracts of Anabaena variabilis and Synechococcus elongates showed a significant antibacterial ratio against Enterococcus sp., Klebsiella sp. and *E. coli*. Malathi et al., (2014) observed significant antibacterial activities of *A. variabilis* in chloroform and methanol crude extracts against *E. coli*. Rania & Taha (2008) reported that Spirulina platensis extracts from different solvents show different degrees of antimicrobial activity on both Gram-positive and Gram-negative microorganisms.

Table 2. The diameter of inhibition zone (DIZ) of the different solvent extracts of *D. affine*.

| Human Pathogen Bacteria | Chloroform DIZ (mm) | Methanol DIZ (mm) | Water DIZ (mm) | Antibiotic Positive Control DIZ (mm) |
|-------------------------|---------------------|-------------------|----------------|-------------------------------------|
| *P. aeruginosa* (ATCC 27853) | 11.7±0.02 | 12.3±0.01 | 8.4±0.03 | GEN 1 |
| *S. dysenteriae* (ATCC 11835) | NCD* | NCD* | NCD* | AMP 2 |
| *E. coli* (ATCC 25924) | 13.8±0.01 | 13.9±0.05 | 8.0±0.02 | 27 |
| *S. aureus* (ATCC 29213) | 12.2±0.03 | 13.5±0.07 | 7.3±0.05 | 13 |
| *B. subtilis* (ATCC 6633) | 13.5±0.06 | 13.6±0.05 | 8.2±0.04 | 13 |
| Negative Controlb | 0 | 0 | 0 | 25 |

*NCD= No Culturable Cells Detected; *Negative Control= Distilled water; (GEN)1: Gentamicin 10 µg; (AMP)2: Ampicillin 10 µg; Data are given as mean ± standard deviation of triplicates. Mean values, n = 3.

Table 3. Antimicrobial index of *D. affine* extracts.

| Human Pathogen Bacteria | Antibiotics | Chloroform Antimicrobial Index in Percentage | Methanol | Water |
|-------------------------|-------------|--------------------------------------------|----------|-------|
| *P. aeruginosa* (ATCC 27853) | GEN | 43 | 46 | 31 |
|                         | AMP | 45 | 47 | 32 |
| *S. dysenteriae* (ATCC 11835) | GEN | NCD* | NCD* | NCD* |
|                         | AMP | NCD* | NCD* | NCD* |
| *E. coli* (ATCC 25924) | GEN | 66 | 66 | 38 |
|                         | AMP | 63 | 63 | 36 |
| *S. aureus* (ATCC 29213) | GEN | 47 | 52 | 28 |
|                         | AMP | 49 | 54 | 29 |
| *B. subtilis* (ATCC 6633) | GEN | 56 | 57 | 34 |
|                         | AMP | 54 | 54 | 33 |

*NCD= No Culturable Cells Detected; (GEN) Gentamicin 10 µg; (AMP) Ampicillin 10 µg.

100% concentration. However, in this study, the extracts in different solvents of *D. affine* against *S. dysenteriae* did not cause any antibacterial effect. It is thought that this may be caused by the species used in the studies and the different solvents.
CONCLUSION
In this study, it was found that extracts of D. affine strain obtained using different solvents have pharmaceutically interesting bioactive compounds. The cyanobacterial extracts obtained showed antibacterial properties against tested pathogenic bacteria, except S. dysenteriae. The present research has shown that the antimicrobial activity of cyanobacterial strains is dependent on the solvents used to make the extracts and the effect of these solvents. Therefore, it is suggested that more detailed studies should be conducted to confirm the effect of antimicrobial activity of crude extracts prepared from different solvents. The future studies aim to identify the bioactive components responsible for antimicrobial effect from cyanobacterial strains by purification. It is thought that the findings obtained from this study can be used for future research and for the production of antibacterial drugs of cyanobacterial origin.
