GENERALIZED CANONICAL RINGS OF $\mathbb{Q}$-DIVISORS ON MINIMAL RATIONAL SURFACES

AARON LANDESMAN, PETER RUHM, AND ROBIN ZHANG

ABSTRACT. We give bounds on the degree of generation and relations of generalized canonical rings of arbitrary $\mathbb{Q}$-divisors on projective spaces of all dimensions and Hirzebruch surfaces. We also give exact bounds on the degree of generators and relations of the generalized canonical ring of any effective $\mathbb{Q}$-divisor on projective space.

1. Introduction

For any Weil $\mathbb{Q}$-divisor $D$ on a rational surface $X$, the graded generalized canonical ring is $R(X,D) := \bigoplus_{d \geq 0} u^d H^0(X, |dD|)$, where $u$ is a dummy variable to keep track of degree. We study the generators and relations of generalized canonical rings for projective spaces $\mathbb{P}^m$ and Hirzebruch surfaces $F_m$. When $D$ is a general $\mathbb{Q}$-divisor on $\mathbb{P}^m$ or $F_m$, we give bounds on the generators and relations of $R(X,D)$. In particular, we give a minimal presentation of the generalized canonical ring when $X = \mathbb{P}^m$ and $D$ is any effective $\mathbb{Q}$-divisor.

In part, this work is motivated by a recent paper by O’Dorney [O15], which gives similar descriptions of generalized canonical rings for general $\mathbb{Q}$-divisors on $\mathbb{P}^1$. This study also has connections to the papers by Voight–Zureick-Brown [VZB15] and Landesman–Ruhm–Zhang [LRZ16], which provide tight bounds on the degree of generators and relations of log canonical rings and log spin canonical rings on arbitrary stacky curves.

Another closely related topic is the Hassett-Keel program [Has05], which aims to describe log canonical models of the form

$$\overline{M}_g(\alpha) := \bigoplus_{d \geq 0} u^d H^0 \left( \overline{M}_g, |dK_{\overline{M}_g} + \alpha \delta| \right)$$

in terms of certain moduli spaces, where $\overline{M}_g$ is the moduli space of stable genus $g$ curves. Moreover, $\mathbb{Q}$-divisors on surfaces also naturally appear when considering the canonical ring of surfaces of Kodaira dimension 1. A surface has Kodaira dimension 1 if and only if it is an elliptic surface [BHPVdV04, p. 244], and the canonical rings of elliptic surfaces are most naturally described in the setting of $\mathbb{Q}$-divisors [BHPVdV04, Chapter V, Theorem 12.1].

1.1. Modular Forms. The work in this paper was motivated by potential applications to calculating a presentation of certain rings of Hilbert modular forms and Siegel modular forms. Recall that Hilbert and Siegel modular forms are two generalizations of modular forms to higher dimensions, as described in [VDG07] and

Date: August 11, 2016.
Voight and Zureick-Brown show that one can translate the analytic category of 1-dimensional complex orbifolds to the algebraic category of stacky curves [VZB15, Proposition 6.1.5]. If one could generalize this result to yield an equivalence of categories between an appropriate subcategory of m-dimensional orbifolds and a subcategory of m-dimensional algebraic spaces, this would allow us to translate rings of Hilbert modular forms and Siegel modular forms whose coarse space is a projective space or a Hirzebruch surface to canonical rings on the corresponding algebraic surfaces. Thereby, if our results could be extended to all rational surfaces, they would give a bound on generators and relations for such rings of Hilbert and Siegel modular forms parameterized by rational Hilbert and Siegel modular surfaces. This would be interesting because such modular surfaces tend to be immensely complicated: “Already for $g = 2$, the boundary of this fundamental domain is complicated; Gottschling found that it possesses 28 boundary pieces” [VDG07, p. 7]. Since our results only apply to minimal rational surfaces, and because the rings of Hilbert and Siegel modular forms are so complex, we were unable to use our work to compute the canonical ring of an explicit modular surface. Although we did not obtain a bound on the degree of generators and relations for general rings of Hilbert and Siegel modular forms parameterized by rational Hilbert and Siegel modular surfaces, they would give a bound on generators and relations for such rings of Hilbert surfaces. This would be interesting because such modular surfaces tend to be immensely complicated. 

1.2. Notation. We now define some notation used throughout the paper. Use $m \in \mathbb{Z}$ to index the dimension of a given projective space $\mathbb{P}^m$ and the type of the Hirzebruch surface $\mathbb{F}_m$. Let $D$ be a (Weil) $\mathbb{Q}$-divisor of the form

$$D = \sum_{i=1}^{n} \alpha_i D_i \in \mathbb{Q} \otimes \text{Div} \ X,$$

where $n \in \mathbb{Z}$ indexes the number of irreducible divisors in the above expansion of $D$, $\alpha_i \in \mathbb{Q}$, and $D_i \in \text{Div} \ X$ is an integral codimension 1 closed subscheme of $X$. When it is convenient to do so, we shall sometimes start the indexing at 0, so that $i$ runs from 0 to $n$. In the case $X = \mathbb{P}^m$, define the degree of $D$ by $\deg D := \sum_{i=1}^{n} \alpha_i \cdot \deg D_i$. The floor of a $\mathbb{Q}$-divisor $D$ is a divisor $\lfloor D \rfloor \in \text{Div} \ X$ is defined to be $\lfloor D \rfloor := \sum_{i=1}^{n} \lfloor \alpha_i \rfloor D_i$. Let $R_D := \bigoplus_{d \geq 0} \mathbb{Q} \otimes \mathbb{H}^0(\mathbb{P}^m, |DD|)$ denote the generalized canonical ring associated to the $\mathbb{Q}$-divisor $D$. So, $R_D$ is notation for $R(X, D)$ when $X$ is understood from context. If $R$ is a graded ring, we denote the $d$th graded component of $R$ by $R_d$. If $r$ is a rational number, we let $\text{frac}(r) := r - \lfloor r \rfloor$ denote the fractional part of $r$. Throughout, we work over a fixed algebraically closed field $k$. Since generator and relation degrees are preserved under base change to the algebraic closure, assuming that $k$ is algebraically closed is no restriction on generality and the results hold equally well over an arbitrary field. If $D \in \mathbb{Q} \otimes \text{Div} \ X$ is an arbitrary divisor, we denote $\mathbb{H}^0(X, D) := \dim_k \mathbb{H}^0(X, D)$.

1.3. Main Results and Outline. In Section 2, we prove the following two results bounding the degree of generators and relations of generalized canonical rings on $\mathbb{P}^m$. The first applies to effective $\mathbb{Q}$-divisors and the second applies to arbitrary $\mathbb{Q}$-divisors.

Theorem 1.1. Let $D = \sum_{i=0}^{n} \alpha_i D_i \in \mathbb{Q} \otimes \text{Div} \mathbb{P}^m$, with $\alpha_i = \frac{c_i}{d_i} \in \mathbb{Q}_{>0}$ in reduced form and each $D_i \in \text{Div} \mathbb{P}^m$ an integral divisor.

Then the generalized canonical ring $R_D$ is generated in degrees at most $\max_{0 \leq i \leq n} k_i$ with relations generated in degrees at most $2 \max_{0 \leq i \leq n} k_i$. 

Remark 1.2. Note that the bounds given in Theorem 1.1 are tight and are typically attained, as explained in Remark 2.8.

Theorem 1.3. Let $D = \sum_{i=0}^{n} \alpha_i D_i \in \mathbb{Q} \otimes_{\mathbb{Z}} \text{Div} \mathbb{P}^m$ with $\alpha_i = \frac{a_i}{b_i} \in \mathbb{Q}$ in reduced form. Write $\ell_i := \text{lcm}_{j \neq i} (k_j)$ and $a_i := \deg D_i$. Let $\mathbb{P}^m \cong \text{Proj} \mathbb{k}[x_0, \ldots, x_m]$ and define $D_i := V(f_i)$, for some $f_i \in \mathbb{k}[x_0, \ldots, x_m]$. Now suppose that $\{f_0, \ldots, f_n\}$ contains $m + 1$ independent linear polynomials in $x_0, \ldots, x_m$ (where we allow for $\alpha_i = 0$ in the expansion of $D$).

Then $\mathbb{R}_D$ is generated in degrees at most $\sum_{i=0}^{n} \ell_i a_i$ with relations generated in degrees at most

$$\max \left( 2 \sum_{i=0}^{n} \ell_i a_i, \frac{\max_{0 \leq i \leq n} (a_i)}{\deg(D)} + \sum_{i=0}^{n} \ell_i a_i \right).$$

Remark 1.4. Note that the bounds given in Theorem 1.3 are asymptotically tight to within a factor of two for a class of divisors described in Remark 2.16.

In Section 3, we shift our attention to Hirzebruch surfaces. Recall that for each $m \geq 0$ we can define the Hirzebruch surface $F_m := \text{Proj}[\text{Sym}^* \mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1}(m)]$ as a projective bundle over $\mathbb{P}^1$. Let $u,v$ be the projective coordinates on the base $\mathbb{P}^1$ and let $z,w$ be the projective coordinates on the fiber, as defined more precisely at the beginning of Chapter 3. Since Hirzebruch surfaces are smooth, the natural map from Cartier divisors to Weil divisors is an isomorphism. In other words, all Cartier divisors arise as the zero locus of a section of some line bundle. We implicitly use this in the statement of the following theorem. The analogous fact for projective space was also implicitly used in Theorems 1.1 and 1.3.

Theorem 1.5. Let $D = \sum_{i=1}^{n} \alpha_i D_i \in \mathbb{Q} \otimes_{\mathbb{Z}} \text{Div} F_m$ where $\alpha_i = \frac{a_i}{b_i} \in \mathbb{Q}$ is written in reduced form. Let each $D_i = V(f_i)$, where $f_i \in \mathcal{O}(a_i, b_i)$. Let $u,v,z,w$ be the coordinates for the Hirzebruch surface $F_m$, and suppose that $\{f_1, \ldots, f_n\}$ contains two independent linear polynomials in $u,v$ and two independent linear polynomials in $w,x$ (where we allow for $\alpha_i = 0$ in the expansion of $D$).

Then $\mathbb{R}_D$ is generated in degrees at most

$$\text{lcm}_{1 \leq i \leq n}(k_i) \cdot \left( \sum_{1 \leq i \leq n} a_i b_i \right)$$

with relations generated in degrees at most

$$2 \cdot \text{lcm}_{1 \leq i \leq n}(k_i) \cdot \left( \sum_{1 \leq i \leq n} a_i b_i \right)$$

Remark 1.6. Theorem 1.5 is restated with a more precise bound in Theorem 3.4.

By the classification of minimal rational surfaces as either $\mathbb{P}^2$ or a Hirzebruch surface [EH87], Theorems 1.3 and 1.5 provide bounds on generators and relations for the generalized canonical ring of any $\mathbb{Q}$-divisor on any minimal rational surface. Section 4 discusses further questions.
2. Canonical Rings of Projective Space

Let \( k \) be a field and let \( \mathbb{P}^m \) denote \( m \)-dimensional projective space over \( k \). In this section, we bound the degrees of generators and relations for divisors on \( \mathbb{P}^m \), for all \( m \geq 1 \) in Theorem 1.1. Note that if \( \deg D < 0 \) the generalized canonical ring is concentrated in degree 0, and if \( \deg D = 0 \), then the generalized canonical ring has a single generator. Therefore, for the remainder of this section, we shall assume \( \deg D > 0 \). The \( \mathbb{P}^1 \) case restricts to the results of [O15]. We also give an explicit description of the generators of the generalized canonical ring \( R_D \) when \( D \) is an effective divisor in Theorem 1.3.

For the remainder of this section, we shall fix \( m \geq 1 \) and choose an isomorphism \( \mathbb{P}^m \cong \text{Proj } V \) for some vector space \( V \) with basis \( x_0, \ldots, x_m \).

2.1. Preliminaries on Projective Space. Before bounding the degree of generation and relations of generalized canonical rings on projective space, we first describe a particular choice of basis for \( R_D \) as a \( k \) vector space.

Write \( D = \sum_{i=0}^{n} \alpha_i D_i \), where \( n \in \mathbb{Z}, \alpha_i \in \mathbb{Q}, \) and \( \deg D_i = a_i \). Choose \( f_i \) so that \( D_i = V(f_i) \). We shall further assume for this subsection that (possibly after reordering) \( f_0, \ldots, f_m \) are \( m \) independent linear forms on \( \mathbb{P}^m \). This may necessitate the inclusion of “ghost divisors” \( D_i \) with coefficients \( \alpha_i = 0 \).

**Proposition 2.1.** The functions \( u^d \cdot \prod_{i=0}^{m} f_i^{c_i} \in (R_D)_d \) satisfying both of the following conditions

1. \( \sum_{i=0}^{m} c_i \cdot a_i = 0 \)
2. \( c_i \geq -\lfloor da_i \rfloor \)

span \( H^0(\mathbb{P}^m, dD) \) over \( k \). Furthermore, such functions that also satisfy

3. \( c_i = -\lfloor da_i \rfloor \) for \( i > m \)

form a basis for \( H^0(\mathbb{P}^m, dD) \) over \( k \).

**Proof.** By definition of \( H^0(\mathbb{P}^m, dD) \), functions satisfying conditions (1) and (2) lie in \( H^0(\mathbb{P}^m, dD) \). To complete the proof, it suffices to check functions satisfying conditions (1-3) form a basis of \( H^0(\mathbb{P}^m, dD) \). Note that there are \( (m + \deg(dD)) \) functions satisfying conditions (1-3). However we know \( h^0(\mathbb{P}^m, dD) = (\frac{m}{m + \deg(dD)}) \), so it suffices to show that those functions satisfying conditions (1-3) are independent. This follows from the assumption that \( f_0, \ldots, f_m \) form a basis of linear forms, and so all monomials in \( f_0, \ldots, f_m \) of degree \( \deg[d(deg D)] \) form a basis of degree \( \deg[dD] \) rational functions.

2.2. Effective Divisors on Projective Space. In this subsection, we restrict attention to the case of effective fractional divisors \( D \in \mathbb{Q} \otimes \text{Div } \mathbb{P}^m \). We give an explicit presentation of the generalized canonical ring when \( D \) is an effective divisor.

**Convention 2.2.** Let \( \mathbb{P}^m \cong \text{Proj } k[x_0, \ldots, x_m] \). Let \( \vec{v} = (v_0, \ldots, v_m) \in \mathbb{Z}^{m+1} \). Then write

\[
\chi^{\vec{v}} := \prod_{i=0}^{m} x_i^{v_i}.
\]
Definition 2.3. For \( \vec{v} \in \mathbb{Z}^n \), denote \( \deg \vec{v} := \sum_{i=0}^{n} v_i \). For a given sequence of numbers \( c_0, \ldots, c_r \), let

\[
S_i := \left\{ \vec{v} \in \mathbb{Z}_{\geq 0}^{m+1} : \deg \vec{v} = c_i \right\}.
\]

Next, we define an ordering on these vectors, which will be used to give a presentation for \( R_D \).

Definition 2.4. Let \( \vec{v}, \vec{w} \in \mathbb{Z}^{m+1} \). Let \( i \in \{0, \ldots, m\} \) be the biggest index such that \( v_i \) is nonzero and \( j \in \{0, \ldots, m\} \) be the smallest index such that \( w_j \) is nonzero. Define a relation on \( \mathbb{Z}^{m+1} \) by \( \vec{v} \prec \vec{w} \) if \( i \leq j \).

We are now ready to give an inductive method for computing the generators and relations of \( R_D \) in terms of \( R_{D'} \). In the case that \( D' = D + \alpha H \) for \( H \) a hyperplane and \( \alpha \) positive. The statement and proofs are natural generalizations of [O13, Theorem 6].

Theorem 2.5. Let \( \mathbb{P}^m \cong \text{Proj}_k[x_0, \ldots, x_m] \). Let \( D' \in \mathbb{Q} \otimes \text{Div} \mathbb{P}^m \) and \( D = D' + \alpha H \), with \( \alpha = \frac{p}{q} \in \mathbb{Q}_{>0} \) and \( H := V(x_k) \) a hyperplane of \( \mathbb{P}^m \). Let

\[
0 = \frac{c_0}{d_0} < \frac{c_1}{d_1} < \cdots < \frac{c_r}{d_r} = \frac{p}{q}
\]

be the convergents of the Hirzebruch-Jung continued fraction of \( \alpha \). Then, the generalized canonical ring

\[
R_D := \bigoplus_{d \geq 0} u^d H^0(\mathbb{P}^m, [dD])
\]

has a minimal presentation over \( R_{D'} \), consisting of the \( \sum_{i=0}^{r} \binom{m+c_i-1}{c_i} \) generators

\[
F_i^\vec{v} := \prod_{\vec{w} \in S_i} F_{\vec{w}}^{g_{\vec{w}}},
\]

where \( 0 \leq i \leq r \), \( \vec{v}, \vec{w} \in \mathbb{Z}_{\geq 0}^{m+1} \) with \( \deg \vec{v} = c_i \). Furthermore, it has relations generated by the following two classes of elements.

1. For each \( (i, j) \) with \( j \geq i + 2 \) and each \( \vec{v}, \vec{w} \in S_i, \vec{w} \in S_j \), there is a relation of the form either

\[
G_{i,j}^\vec{v} \vec{w} = F_i^\vec{v} F_j^\vec{w} - \prod_{\vec{g} \in S_{h_{i,j}}} (F_{\vec{g}}^{\vec{h}_{i,j}})^{g_{\vec{g}}},
\]

\( (i < h_{i,j} < j) \)

or

\[
G_{i,j}^\vec{v} \vec{w} = F_i^\vec{v} F_j^\vec{w} - \prod_{\vec{g} \in S_{h_{i,j}}} (F_{\vec{g}}^{\vec{h}_{i,j}})^{g_{\vec{g}}} \prod_{\vec{z} \in S_{h_{i,j}+1}} (F_{\vec{z}}^{\vec{h}_{i,j}+1})^{g_{\vec{z}}},
\]

\( (i < h_{i,j} < h_{i,j} + 1 < j) \).

2. For each \( (i, j) \) with \( j = i \) or \( j = i + 1 \) and each \( \vec{v} \in S_i, \vec{w} \in S_j \) with \( \vec{v} \neq \vec{w} \) (see Definition 2.7), there is a relation of the form

\[
L_{i,j}^\vec{v} \vec{w} = F_i^\vec{v} F_j^\vec{w} - F_i^\vec{g} F_j^\vec{f},
\]

where \( \vec{g} \) and \( \vec{f} \) are the unique vectors in \( S_i \) and \( S_j \), respectively, such that \( \vec{g} + \vec{f} = \vec{v} + \vec{w} \) and \( \vec{g} \prec \vec{f} \).
Suppose \( F \) so in the theorem statement. Since we wrote an arbitrary monomial \( u_\alpha \). Theorem 6] demonstrates that each lattice point \( (m > 1 \). We can then write \( D \) instead of rational sections of \( O_D \). Therefore, none of the \( F \) are redundant.

Next we show that \( F_1 \) determine a system of minimal generators of \( R_D \). In the case \( m = 1 \), O’Dorney [O15 Theorem 6] demonstrates that each lattice point \( (\beta, \gamma) \in \mathbb{Z}_{\geq 0}^2 \) with \( \gamma \leq \beta \alpha \) lies in the \( \mathbb{Z}_{\geq 0} \) span of \( (d_h, c_h) \) and \( (d_{h+1}, c_{h+1}) \) for some \( h \in \{0, \ldots, r\} \). A similar strategy works in the case \( m > 1 \). Let \( (\beta, \gamma) = \kappa_1(d_h, c_h) + \kappa_2(d_{h+1}, c_{h+1}) \) for \( \kappa_1, \kappa_2 \in \mathbb{Z}_{\geq 0} \). Any element \( \begin{pmatrix} \beta \\ \gamma \end{pmatrix} \in R_D \) is expressible as

\[
\begin{pmatrix} u \beta x^\gamma \\ x_k \end{pmatrix} = \begin{pmatrix} \prod_{\lambda=1}^{\kappa_1} u_{d_h} x_{h\lambda}^{w_{(\lambda)}} \prod_{\eta=1}^{\kappa_2} u_{d_{h+1}} x_{h+1\eta}^{z_{(\eta)}} \\ x_k \end{pmatrix}
\]

We can then write \( \tilde{v} = \sum_{\lambda=1}^{\kappa_1} \tilde{w}_{(\lambda)} + \sum_{\eta=1}^{\kappa_2} \tilde{z}_{(\eta)} \) with \( w_{(\lambda)} \in S_h \) and \( z_{(\eta)} \in S_{h+1} \) to give a decomposition

\[
(2.1) \quad \begin{pmatrix} u \beta x^\gamma \\ x_k \end{pmatrix} = \prod_{\lambda=1}^{\kappa_1} u_{d_h} x_{h\lambda}^{w_{(\lambda)}} \prod_{\eta=1}^{\kappa_2} u_{d_{h+1}} x_{h+1\eta}^{z_{(\eta)}}
\]

consisting of products of generators \( F_{h}(\gamma, \lambda) \) and \( F_{h+1}(\eta) \) which are in the form prescribed in the theorem statement. Since we wrote an arbitrary monomial \( \frac{u^\beta x^\gamma}{x_k} \in R_D \) as a product of generators, this shows that \( F_1 \) minimally generate \( R_D \).

Next, we show that the relations given in the statement of the theorem generate all relations. In particular, if \( j \geq i + 2 \) then \( F_j F_i \) has a decomposition of the form (2.1) of products of generators in adjacent degrees where \( h \) depends on \( i \) and \( j \), so we note that \( h_{i,j} := h \in \{1, \ldots, r\} \). We also have that \( i \leq h_{i,j} < j \) since \( (d_i +
$d_i,c_i+c_j$ is in the $\mathbb{Z}_{\geq 0}$-span of $(d_{h_{i,j}},c_{h_{i,j}})$ and $(d_{h_{i,j}+1},c_{h_{i,j}+1})$. Furthermore, $h_{i,j} \neq i$ and $h_{i,j} \neq j-1$ as follows from an analogous proof to that given by O’Dorney [O15, Theorem 6] for the case of $\mathbb{P}^1$. This gives the relations $G_{i,j}^\vec{v}$. One can use the relations $G_{i,j}^\vec{v}$, $G_{j,i}^\vec{w}$ to transform any monomial in the $F_i^\vec{v}$’s involving indices that differ by more than 1 to a monomial in the $F_i^\vec{v}$’s involving indices that differ by at most 1.

We also have relations involving generators in consecutive indices. Suppose $F_i^\vec{v}$ and $F_j^\vec{w}$ are generators with $j = i$ or $j = i+1$ and $\vec{v} \in S_i, \vec{w} \in S_j$ with $\vec{v} \neq \vec{w}$. Let $\vec{y}$ and $\vec{z}$ be the unique vectors in $S_i$ and $S_j$, respectively, such that $\vec{y} + \vec{z} = \vec{v} + \vec{w}$ and $\vec{y} \prec \vec{z}$ (i.e. the nonzero indices of $\vec{y}$ followed by those of $\vec{z}$ give an increasing sequence). Then we see that

$$F_i^\vec{v} F_j^\vec{w} = x^{\vec{y}+\vec{w}} \left( \frac{u_{d_i}}{x^{c_i}} \right) \left( \frac{u_{d_j}}{x^{c_j}} \right) = x^{\vec{y}+\vec{z}} \left( \frac{u_{d_i}}{x^{c_i}} \right) \left( \frac{u_{d_j}}{x^{c_j}} \right) = F_i^\vec{y} F_j^\vec{z},$$

which give the relations $L_{i,j}^\vec{v},\vec{w}$.

Now, we may apply the relations $L_{i,j}^\vec{v},\vec{w}$ to any monomial in the $F_i^\vec{v}$’s involving indices that differ by at most 1 to produce the canonical form

$$(F_i^\vec{v}_1)^{g_{\vec{v}_1}(1)} \cdots (F_i^\vec{v}_{s_1})^{g_{\vec{v}_{s_1}}(1)} (F_{i+1}^\vec{w}_1)^{g_{\vec{w}_1}(1)} \cdots (F_{i+1}^\vec{w}_{s_2})^{g_{\vec{w}_{s_2}}(1)},$$

where $\vec{v}_1 < \vec{v}_2 < \ldots < \vec{v}_{s_1} < \vec{w}_1 < \ldots < \vec{w}_{s_2}$. Consequently, the relations of form $G_{i,j}^\vec{v}$, $G_{j,i}^\vec{w}$, and of form $L_{i,j}^\vec{v},\vec{w}$ generate all the relations among the $F_i^\vec{v}$.

**Remark 2.6.** In the case that $D = \alpha_0 D_0$ is supported on a single hypersurface, the relations in Theorem 2.5 form a reduced Gröbner basis with respect to the ordering given in Definition 2.4.

**Remark 2.7.** Note that we cannot extend this result to the case when $D$ is supported at two hypersurfaces with arbitrary rational (non-effective) coefficients in the same manner that O’Dorney does for the $\mathbb{P}^1$ case [O15, Section 4]. As will be shown in Example 2.9, the degrees of generation of the generalized canonical ring of a general $\mathbb{Q}$-divisor supported on two hyperplanes cannot be bounded so tightly. The two-point $\mathbb{P}^1$ result leverages the fact that $\mathbb{P}^1$ has precisely two independent coordinates, so that two distinct integral subschemes cannot represent equations of only $m$ of the $m+1$ coordinates.

Theorem 2.5 gives an inductive procedure to compute presentations of effective divisors which are supported on hyperplanes. However, for $m \geq 2$, there are hypersurfaces which are not unions of hyperplanes. We now address this general case, giving an inductive presentation of generalized canonical rings of effective divisors, and a tight bound on the degrees of their generators and relations.

**Theorem 1.1.** Let $D = \sum_{i=0}^{n} \alpha_i D_i \in \mathbb{Q} \otimes \text{Div } \mathbb{P}^m$, with $\alpha_i = \frac{\alpha_i}{k_i} \in \mathbb{Q}_{>0}$ in reduced form and each $D_i \in \text{Div } \mathbb{P}^m$ an integral divisor.

Then the generalized canonical ring $R_D$ is generated in degrees at most $\max_{0 \leq i \leq n} k_i$ with relations generated in degrees at most $2 \max_{0 \leq i \leq n} k_i$.

**Proof.** We proceed by induction on $n$. If $n = 0$, i.e. $D = 0$, then we are done. Now, we inductively add hypersurfaces. Let $D' = \sum_{i=0}^{n+1} \alpha_i D_i \in \mathbb{Q} \otimes \text{Div } \mathbb{P}^m$, and assume the theorem holds for $D'$. It suffices to show the theorem holds for $D \in \text{Div } \mathbb{Q} \otimes \mathbb{P}^m$, where $D = D' + \alpha C$ for some degree $\delta$ hypersurface $C$. If $C$ were a hyperplane, we would then be done, by Theorem 2.5.
To complete the theorem, we reduce the case that $C$ is a general hypersurface to the case that $C$ is a hyperplane, by using the Veronese embedding.

If $C$ is of degree $\delta$, consider the Veronese embedding $\nu^m_\delta: \mathbb{P}^m \to \mathbb{P}^{(m+\delta)-1}$ so that the image of $C$ is the intersection of a hyperplane in $\mathbb{P}^{(m+\delta)-1}$ with $\nu^m_\delta(\mathbb{P}^m)$. Now, note that the ring $R_{\alpha C}$ is isomorphic to the $\delta$ Veronese subring of $R_{\alpha V(x_0)} = \bigoplus_{d \geq 0} u^d H^0(\mathbb{P}^m, d\alpha V(x_0))$ and so the generalized canonical ring $R_H$ of the hyperplane $H \subset \mathbb{P}^{(m+\delta)-1}$ restricted to $\nu^m_\delta(C)$ is isomorphic to $R_C$. Therefore, we can bound the degree of generators and relations of $R_D$ over $R_H$, by the degree of generators and relations for $R_C \cong R_H$. This reduces the case of a hypersurface $C$ to a hyperplane $H$, completing the proof by Theorem 2.5.

**Remark 2.8.** Note that the proof of Theorem 2.1 not only gives bounds on the degrees of the generators and relations, but actually gives an explicit method for computing the presentation. In particular, these bounds are tight. The generator bound is always achieved and the bound on the relations is achieved if $m \geq 2$.

### 2.3. Bounds for Arbitrary Divisors on Projective Space

We now offer bounds on generators and relations of $R_D$ for a general $\mathbb{Q}$-divisor $D \in \mathbb{Q} \otimes \text{Div} \mathbb{P}^m$.

Let $D = \sum_{i=0}^n a_i D_i \in \mathbb{Q} \otimes \text{Div} \mathbb{P}^m$ and let $f_i$ be homogeneous polynomials in $x_0, \ldots, x_m$ such that $D_i = V(f_i)$ and $\deg(f_i) = a_i$ for all $i$.

The first aim of this section is to prove Theorem 1.3 bounding the number of generators and relations for $R_D$. Before doing so, we justify the importance of assumption (2.2) with several illustrative examples.

**Example 2.9.** In this example, we show that the naive generalization of [15, Theorem 8] of generation in degree at most $\sum_{i=0}^n a_i$ cannot possibly hold. The reason for this is that the divisors may be expressible as functions in $m$ of the $m+1$ variables on $\mathbb{P}^m$.

Concretely, take $D = \frac{1}{7} H_0 - \frac{1}{3} H_1$ where $H_0 = V(x_0), H_1 = V(x_1)$ are two coordinate hyperplanes in $\mathbb{P}^2$. Then, $R_D$ has generators in degree 2 and 3, which can be written as $u^2 \frac{x_0}{x_2}, u^3 \frac{x_1}{x_2}$. In fact, for all degrees less than 5, the elements of $R_D$ can all be expressed as rational functions in $x_0, x_1$. However, in degree 6, there is $u^6 \cdot \frac{x_0^2 x_1}{x_2^3}$. Since this involves $x_2$, it must be a generator.

This example generalizes slightly to any divisor of the form $D = \frac{k}{7} H_0 - \frac{1}{3} H_1 \in \mathbb{Q} \otimes \text{Div} \mathbb{P}^2$, with $k \in \mathbb{N}$, showing that there will always exist a generator in degree $k(k+1)$.

This example further generalizes to the following situation: Suppose $D = \sum_{i=0}^n \frac{p_i}{q_i} D_i \in \mathbb{Q} \otimes \text{Div} \mathbb{P}^m$, where $\deg D_i = a_i$ and $\deg D = \frac{1}{\lcm_{0 \leq i \leq n}(q_i a_i)}$. Then, if $D_i = V(f_i)$ where all $f_i$ can be written as a polynomial function in $x_0, \ldots, x_{m-1}$, it follows that $R_D$ always has a generator in degree $\lcm(q_i a_i)$.

As illustrated in Example 2.9 when all components in the support of divisor can be written in terms of $m$ of the $m+1$ variables on $\mathbb{P}^m$, we cannot hope to...
bound the degree of generation by anything less than the sum of the least common multiples of the denominators. This issue can easily be circumvented by adding in “ghost points.” That is, we may add divisors of the form $0 \cdot H_i$ to $D$, and reorder so that if $D = \sum_{i=0}^{n} \alpha_i V(f_i)$, then $f_0, \ldots, f_m$ are independent linear functions in $x_0, \ldots, x_m$.

In Example 2.10 we show that it is still, in general, necessary to add ghost points, even when the irreducible components of a divisor are not all expressible as functions in $m$ of the $m + 1$ variables on $\mathbb{P}^m$.

**Example 2.10.** Consider $-\frac{1}{3} V(x_0^2 + x_1^2 + x_2^2) + \frac{1}{5} V(x_0^2 + x_1^2 + x_3^2) + \frac{1}{9} V(x_0^2 + x_2^2 + x_3^2) - \frac{1}{25} V(x_1^2 + x_2^2 + x_3^2)$. In degree 355216 = $5 \cdot 7 \cdot 17 \cdot 596$, this has dimension 6. However, we cannot hope to bound the degree of generation of $R_D$ as a linear combination of extremal rays of an associated cone. We now carry out this strategy.

**Proposition 2.11.** Let $n \in \mathbb{Z}$, let $\alpha_0, \ldots, \alpha_n \in \mathbb{Q}$, and let $a_i, b_i \in \mathbb{Z}$ with $0 \leq i \leq n$. Define

$$\Sigma := \left\{ (d, c_0, \ldots, c_n) \in \mathbb{Z}^{n+2} : c_i \geq -d \alpha_i, 0 \leq i \leq n \text{ and } \sum_{i=0}^{n} a_i = \sum_{i=0}^{n} b_i = 0 \right\}.$$

Suppose $e_0, \ldots, e_t \in \Sigma$ with $e_i = (\delta_i, c_{i0}, \ldots, c_{in})$ are a set of extremal rays of $\Sigma$, i.e. $\Sigma$ is contained in the $\mathbb{Q}_{>0}$ span of $e_0, \ldots, e_n$.

Then, as a semigroup, $\Sigma$ is generated by elements whose first coordinate is less than $\sum_{i=0}^{t} \delta_i$. Furthermore, every element $\sigma \in \Sigma$ can be written in a canonical form

$$\sigma = \lambda + \sum_{i=0}^{t} \zeta_i e_i$$

with $\zeta_1, \ldots, \zeta_t \in \mathbb{Z}_{\geq 0}$, $0 \leq s_i < 1$, and $\lambda = \sum_{i=0}^{t} s_i e_i$ so that the first coordinate of $\lambda$ is less than $\sum_{i=0}^{t} \delta_i$.

**Proof.** By assumption, $\sigma \in \Sigma$ can be written as $\sigma = \sum_{i=0}^{t} r_i e_i$ with $r_i \in \mathbb{Q}$. Let $\text{frac}(r) := r - [r]$ denote the fractional part of $r$. Let $\lambda = \sum_{i=0}^{t} \text{frac}(r_i)$. Whence, we can write $\sigma = \lambda + \sum_{i=0}^{t} [r_i] e_i$. Consequently, $\sigma$ lies in the $\mathbb{Z}_{\geq 0}$ span of $\lambda, e_0, \ldots, e_t$, which all have first coordinate less than $\sum_{i=0}^{t} \delta_i$. Ergo, $\Sigma$ is generated by elements whose first coordinate is less than $\sum_{i=0}^{t} \delta_i$. □

By Proposition 2.11 in order to bound the degree of generation of $R_D$, we only need bound the degrees of extremal rays of an associated cone. We now carry out this strategy.
Lemma 2.12. Let $D = \sum_{i=0}^{n} \alpha_i D_i \in \mathbb{Q} \otimes_{\mathbb{Z}} \text{Div } \mathbb{P}^m$, where $\deg D_i = \alpha_i$, $\alpha_i = \frac{c_i}{k_i} \in \mathbb{Q}$, and $k_i = \text{lcm}_{j \neq i} (k_j)$. Then, $R_D$ is generated in degrees at most $\sum_{i=0}^{n} k_i \alpha_i$.

Proof. Let

$$\Sigma = \left\{ (d, c_0, \ldots, c_n) \in \mathbb{Z}^{n+2} : c_i \geq -d \alpha_i, 0 \leq i \leq n, \text{ and } \sum_{i=0}^{n} k_i \alpha_i = 0 \right\}.$$  

Observe that $\Sigma$ has extremal rays given by the lattice points

$$\epsilon_i = \left( \ell_i \alpha_i - \alpha_0 \ell_i \alpha_i, \ldots, -\alpha_{i-1} \ell_i \alpha_i, \ell_i \sum_{j \neq i} \alpha_j \alpha_j - \alpha_{i-1} \ell_i \alpha_i, \ldots, -\alpha_n \ell_i \alpha_i \right)$$

for each $i \in \{0, \ldots, n\}$. Therefore, applying Proposition 2.11, we see $R_D$ is generated in degrees less than

$$\sum_{i=0}^{n} \ell_i \alpha_i.$$

$\square$

Let $w_1, \ldots, w_r$ be the generators in degrees at most $\sum_{i=0}^{n} \ell_i \alpha_i$ (given by Lemma 2.12), and let $\phi : \mathbb{k}[w_1, \ldots, w_r] \to R_D$ be the natural surjection. For the remainder of the section, we aim to bound the degree of relations of $R_D$, or equivalently, the degree of generation of $\ker \phi$. We can factor $\phi$ through the semigroup ring

$$\mathbb{k}[\Sigma] = \langle u^d z_0^{c_0} \cdots z_n^{c_n} : c_i \in \mathbb{Z}, c_i \geq -d \alpha_i, \text{ and } \sum_{i=0}^{n} \alpha_i c_i = \sum_{i=0}^{n} b_i c_i \rangle.$$

by

$$\begin{array}{cccc}
\mathbb{k}[w_1, \ldots, w_r] & \xrightarrow{\chi} & \mathbb{k}[\Sigma] & \xrightarrow{\psi} & R_D \\
\phi & & & & \\
\downarrow \hspace{4cm} & & & & \\
\downarrow \hspace{4cm} & & & & \\
w_1 & \longrightarrow & u^d_1 z_0^{c_1} \cdots z_n^{c_n} & \longrightarrow & u^d_1 f_0^{c_1} \cdots f_n^{c_n}. \\
\end{array}$$

In Lemma 2.13 we show that the degree of the generators for $\ker \phi$, which is the same as the degree of relations of $R_D$, is bounded by the maximum of the degree of generators for $\ker \chi$ and for $\ker \psi$. In Lemma 2.14 we bound the degree of generation of $\ker \chi$, and we bound the degree of generation of $\ker \psi$ in Lemma 2.15

Lemma 2.13. Let $X$ be an arbitrary scheme and let $D = \sum_{i=0}^{n} \alpha_i D_i \in \mathbb{Q} \otimes_{\mathbb{Z}} \text{Div } X$ where $D_i = \mathbb{V}(f_i)$. Suppose we have a surjection $\phi : \mathbb{k}[w_1, \ldots, w_r] \to R_D$ given by $w_i \mapsto p_i(f_0, \ldots, f_n)$, where $p_i$ is a monomial in $f_0, \ldots, f_n$. Let $a_0, \ldots, a_n, b_0, \ldots, b_n \in \mathbb{Z}_{\geq 0}$. Then, define

$$\Sigma = \langle u^d z_0^{c_0} \cdots z_n^{c_n} : c_i \geq -d \alpha_i, \sum_{i=0}^{n} a_i c_i = \sum_{i=0}^{n} b_i c_i = 0 \rangle.$$ 

In this case, we can factor $\phi$ as a composition of $\chi$ and $\psi$ defined by

$$\begin{array}{cccc}
\mathbb{k}[w_1, \ldots, w_r] & \xrightarrow{\chi} & \mathbb{k}[\Sigma] & \xrightarrow{\psi} & R_D \\
\phi & & & & \\
\downarrow \hspace{4cm} & & & & \\
w_1 & \longrightarrow & u^d_1 z_0^{c_1} \cdots z_n^{c_n} & \longrightarrow & u^d_1 f_0^{c_1} \cdots f_n^{c_n}. \\
\end{array}$$
Assuming \( \chi \) is surjective, the minimal degree of generation of \( \ker \phi \) is at most the maximum of the minimal degree of generation of \( \ker \chi \) and the minimal degree of generation of \( \ker \psi \).

**Proof.** First, note that surjectivity of \( \chi \) implies we have an exact sequence

\[
0 \longrightarrow \ker \chi \longrightarrow \ker \phi \longrightarrow \ker \psi \longrightarrow 0.
\]

This shows that lifts of generators of \( \ker \psi \) together with images of generators of \( \ker \chi \) generate all of \( \ker \phi \), as desired. \( \square \)

**Lemma 2.14.** Retaining the notation of Lemma 2.13, if \( \Sigma \) has extremal rays \( e_0, \ldots, e_t \) in degrees \( d_0, \ldots, d_t \) then \( \ker \chi \) is generated in degrees at most \( 2(\sum_{i=0}^{t} d_i - 1) \).

**Proof.** Since \( e_0, \ldots, e_t \) are extremal rays, Proposition 2.11 implies every element \( \sigma \in \Sigma \) can be written in a canonical form \( \lambda + \sum_{i=0}^{t} \zeta_i e_i \) where all \( \zeta_i \in \mathbb{Z}_{\geq 0} \). Let \( \lambda_0 := \lambda_1, \ldots, \lambda_t \) be all elements of \( \Sigma \) which can be written in the form \( \lambda_j = \sum_{i=0}^{t} s_i e_i \) with \( 0 \leq s_i < 1 \). Then, for any \( 1 \leq j \leq k \leq t \), we can write \( \lambda_j + \lambda_k \) in the above canonical form, yielding a (possibly trivial) relation in degree at most \( \deg \lambda_j + \deg \lambda_k \leq 2 \cdot (\sum_{i=0}^{t} d_i - 1) \). Furthermore, these relations generate all relations, as one can apply a sequence of these relations to put any \( \sigma \in \Sigma \) into canonical form \( \sigma = \lambda + \sum_{i=0}^{t} \zeta_i e_i \) from Proposition 2.11. \( \square \)

**Lemma 2.15.** Let \( D = \sum_{i=0}^{n} \alpha_i D_i \in \mathbb{Q} \otimes \mathbb{Z} \text{Div} \mathbb{P}^m \), where \( \deg D_i = \alpha_i \), \( \alpha_i = \frac{c_i}{\ell_i} \in \mathbb{Q} \), and \( \ell_i = \text{lcm}_{j \neq i}(k_j) \). Define \( \Sigma \) as in Equation 2.4 and \( \psi \) as in Equation 2.6. Then, \( \ker \psi \) is generated in degrees at most

\[
\frac{\max_{0 \leq i \leq n} (\alpha_i)}{\deg(D)} + \sum_{i=0}^{n} \ell_i a_i.
\]

**Proof.** We claim there exist \( \beta_0, \ldots, \beta_n \in \mathbb{k}[\Sigma] \) such that \( \ker \psi \) is generated by

\[
u^d(z_i - \beta_i) \prod_{j=0}^{n} z_j^{c_j}
\]

for all \( d \in \mathbb{N} \) and \( c_i \geq -a_i \) satisfying \( a_i + \sum_{j=0}^{n} a_j c_j = 0 \).

Indeed, define the \( \beta_i \) as a polynomial in \( z_0, \ldots, z_m \) such that \( \psi(\beta_i) = \psi(z_i) = f_i \in \mathbb{R}_D \). This is possible by Proposition 2.4. Furthermore, the relations given in Equation 2.8 generate all relations, since they allow us to reduce any \( u^{d_i} \prod_{j=0}^{n} z_j^{c_{j,i}} \) to a canonical form, with \( c_i = -[d \alpha_i] \) whenever \( i > m \).

For the remainder of the proof, fix \( i \in \{0, \ldots, n\} \). To complete the proof, it suffices to bound the degree of generation of the relations of the form \( u^{d_i}(z_i - \beta_i) \prod_{j=0}^{n} z_j^{c_{j,i}} \), by Equation 2.7. For a given monomial \( u^{d_i}(z_i - \beta_i) \prod_{j=0}^{n} z_j^{c_{j,i}} \in \mathbb{k}[\Sigma] \), we associate it with the corresponding element \( (d_i, c_0, \ldots, c_n) \in \Sigma \). Let \( \Sigma_i \subseteq \mathbb{Z}^{n+2} \) be the set of points of the form \( (d_i, c_0, \ldots, c_n) \) satisfying \( c_j \geq -d \alpha_j \) for all \( j \) and \( \sum_{j=0}^{n} c_j a_j = -a_i \). Let

\[
\delta_i := \left( \frac{a_i}{\deg(D)}, \frac{-\alpha_0 a_0}{\deg(D)}, \ldots, \frac{-\alpha_n a_n}{\deg(D)} \right).
\]
Then we see $\Sigma_i = \{ \sigma \in \Sigma | \sigma - \delta_i \in \text{span}_{Q \geq i}(e_0, \ldots, e_n) \}$ with $e_i$ as defined in Equation 2.15. Therefore, we can write any element of $\Sigma_i$ uniquely as
\[
\delta_i + \sum_{j=0}^{n} c_j e_j
\]
where $c_j \in \mathbb{R}$ for each $j$.

Whenever some there is some $j$ for which $c_j > 1$, we can write the relation $u^D(z_i - \beta_i) \prod_{j=0}^{n} z_j^{c_j} = e_i h$, for some $h \in \Sigma_i$. Therefore, for a fixed $i$, relations of the form $u^D(z_i - \beta_i) \prod_{j=0}^{n} z_j^{c_j} \in k[\Sigma]$ are generated by those in degrees less than
\[
\frac{a_i}{\deg(D)} + \sum_{i=0}^{n} \ell_i a_i,
\]
as $\deg \delta_i = \frac{a_i}{\deg(D)}$. Hence, $\ker \psi$ is generated in degrees less than
\[
\frac{\max_{0 \leq i \leq n} a_i}{\deg(D)} + \sum_{i=0}^{n} \ell_i a_i.
\]

By combining the above results, we get our main theorem bounding the generator and relation degrees of the generalized canonical ring of any $Q$-divisor on projective space.

**Theorem 1.3.** Let $D = \sum_{i=0}^{n} \alpha_i D_i \in \mathbb{Q} \otimes \mathbb{Z} \text{Div } \mathbb{P}^m$ with $\alpha_i = \frac{c_i}{k_i} \in \mathbb{Q}$ in reduced form. Write $f_i := \text{lcm}_{j \neq i}(k_j)$ and $a_i := \deg D_i$. Let $\mathbb{P}^m = \text{Proj} k[x_0, \ldots, x_m]$ and define $D_i := V(f_i)$, for some $f_i \in k[x_0, \ldots, x_m]$. Now suppose that $\{f_0, \ldots, f_n\}$ contains $m + 1$ independent linear polynomials in $x_0, \ldots, x_m$ (where we allow for $\alpha_i = 0$ in the expansion of $D$).

Then $R_D$ is generated in degrees at most $\sum_{i=0}^{n} \ell_i a_i$ with relations generated in degrees at most
\[
\max \left( 2 \sum_{i=0}^{n} \ell_i a_i, \frac{\max_{0 \leq i \leq n} (a_i)}{\deg(D)} + \sum_{i=0}^{n} \ell_i a_i \right).
\]

**Proof.** The bound on degree of generation is precisely the content of Lemma 2.12. It only remains to bound the degree of relations.

By 2.14, $\ker \chi$ is generated in degrees at most $2 \sum_{i=0}^{n} \ell_i a_i$ and by Lemma 2.15, $\ker \phi$, is generated in degrees up to $\frac{\max_{0 \leq i \leq n} (a_i)}{\deg(D)} + \sum_{i=0}^{n} \ell_i a_i$. Consequently, Lemma 2.14 implies that $\ker \phi$ is generated in degrees less than
\[
\max \left( 2 \sum_{i=0}^{n} \ell_i a_i, \frac{\max_{0 \leq i \leq n} (a_i)}{\deg(D)} + \sum_{i=0}^{n} \ell_i a_i \right).
\]

**Remark 2.16.** The bounds given in Theorem 1.3 are asymptotically tight to within a factor of two for the following class of divisors. Consider a divisor $D = \sum_{i=0}^{n} \frac{p_i}{q_i} H_i \in \mathbb{Q} \otimes \mathbb{Z} \text{Div } \mathbb{P}^m$ such that $H_i$ are hyperplanes, $q_i$ are pairwise coprime integers, and $p_i$ are chosen so that $\deg D = \frac{1}{\prod_{i=0}^{n} q_i}$. Further, choose a linear subspace $\pi : \mathbb{P}^1 \rightarrow \mathbb{P}^m$ generically so that $\pi^* D = \sum_{i=0}^{n} \frac{p_i}{2q_i} P_i$, where $P_i$ are distinct points.
in \( \mathbb{P}^1 \). To choose such a map \( \pi \), we may need to assume that the base field is infinite. Note that by the Remark immediately following Theorem 8 in [O15], the given bounds on the generators and relations of \( R_{\pi^*D} \) are within a factor of two of the degree of generation and relations of \( R_{\pi^*D} \). Finally, since restriction map \( R_D \to R_{\pi^*D} \) induced by the restriction maps on cohomology \( H^0(\mathbb{P}^m, dD) \to H^0(\mathbb{P}^1, \pi^*(dD)) \cong H^0(\mathbb{P}^1, d\pi^*D) \) are surjective, we obtain that the bounds for the generators and relations of \( R_D \) given in Theorem 1.3 also agree with the degree of generation and relations to within a factor of two.

3. Canonical Rings of Hirzebruch surfaces

The aim of this section is to prove Theorem 1.5, bounding the degree of generators and relations of the generalized canonical ring of a \( \mathbb{Q} \)-divisor on any Hirzebruch surface.

One way to describe the Hirzebruch surface \( F_m \) is as a quotient,

\[
F_m \cong (\mathbb{A}^2 \setminus \{0\}) \times (\mathbb{A}^2 \setminus \{0\}) / G_m \times G_m
\]

where \( G_m \) is the multiplicative subgroup of \( \mathbb{A}^1 \), and the action of \( G_m \times G_m \) is given by \( (\lambda, \mu) \cdot (u; v; z; w) = (\lambda u; \lambda v; \mu z; \mu w) \), as described in [Zha14, p. 6]. Hence, one can think of \( F_m \) as a \( \mathbb{P}^1 \) bundle where \( u,v \) are the coordinates on \( \mathbb{P}^1 \) and \( z,w \) are the coordinates on the fiber. Sections of a line bundle \( L \) on \( F_m \) can be written as rational functions in \( z,w,u,v \). Furthermore, we define the bi-degree of a monomial \( a^b z^c w^d \) on \( F_m \) to be \( (a + b + mc, c + d) \). Rational sections of \( F_m \) can be written as rational functions with numerators and denominators with the same bi-degrees. To see this, observe \( \text{Pic}(F_m) \cong \mathbb{Z} \times \mathbb{Z} \), where the class of a line bundle in \( \text{Pic}(F_m) \) is determined by its bi-degree, as follows from the excision exact sequence for class groups.

Furthermore, similarly to the case of projective space, we will restrict to the case that \( D \) is a divisor for which both of its bi-degrees are positive. We now justify this restriction. If either of the bi-degrees of \( D \) is negative, then the generalized canonical ring is concentrated in degree 0. If one of the bi-degrees is 0, say the first one is 0, then \( R_D \) is isomorphic to \( R_{\pi^*D} \), where \( D' = \pi^*D \to \mathbb{P}^1 \), where \( D' \) can be written as a sum of divisors whose degrees are multiples of the second bi-degree of \( D \). Since the case of \( \mathbb{P}^1 \) has already been analyzed in [O15], we are justified in assuming that both bi-degrees of \( D \) are positive.

For the remainder of this section we will assume \( D_1, D_2, D_3, \) and \( D_4 \) are distinct divisors with bi-degrees \( (1,0), (1,0), (0,1) \), and \( (0,1) \) respectively with \( D_i = V(f_i) \) for \( 1 \leq i \leq 4 \) with \( f_i \in \mathcal{O}(a_i, b_i) \). In order to achieve the above condition on the bi-degrees of \( D_1, \ldots, D_4 \), it may be necessary to add in “ghost divisors” (i.e. divisors with of the desired form with a coefficient 0). Also, note that, \( f_1 \) and \( f_2 \) are independent linear polynomials in \( u \) and \( v \) and \( f_3 \) and \( f_4 \) are independent linear polynomials in \( z \) and \( w \). Analogously to Proposition 2.1 for the case of \( \mathbb{P}^m \), all rational functions on \( F_m \) can be written uniquely in a form where their numerator is a function of only \( f_1, f_2, f_3, \) and \( f_4 \).

**Definition 3.1.** Define

\[
T_\pi(D) = \left\{ i \in \{1, \ldots, n\} : a_i \sum_{k=1}^n b_k \alpha_k = b_i \sum_{k=1}^n a_k \alpha_k \right\},
\]
\[ T_+(D) = \left\{ i \in \{1, \ldots, n\}: a_i \sum_{k=1}^{n} \alpha_k b_k > b_i \sum_{k=1}^{n} \alpha_k a_k \right\}, \]

and

\[ T_-(D) = \left\{ i \in \{1, \ldots, n\}: a_i \sum_{k=1}^{n} \alpha_k b_k < b_i \sum_{k=1}^{n} \alpha_k a_k \right\}. \]

**Lemma 3.2.** For \( D = \sum_{i=1}^{n} e_i \in \text{Div} \mathbb{Q} \otimes \mathbb{Z} F_m \), with \( \deg D_i = (a_i, b_i), \ell_i = \text{lcm}_{j \neq i} (k_j), \ell_{i,j} = \text{lcm}_{h \neq i,j} (k_h) \). Then, the generalized canonical ring \( R_D \) is generated in degrees at most

\[ (3.1) \quad \rho := \sum_{i \in T_+(D)} \gcd(a_i, b_i)\ell_i + \sum_{i \in T_+(D), j \in T_-(D)} (a_i b_j - a_j b_i)\ell_{i,j}. \]

**Proof.** Suppose \( g \in (R_D)_d \) is a monomial. Then

\[ g = u^d \prod_{i=1}^{n} f_i^{c_i} \]

for some \( c_i \geq -\alpha_i, d \) such that \( \sum_{i=1}^{n} c_i a_i = 0 \) and \( \sum_{i=1}^{n} c_i b_i = 0 \). We can view \( g \) as an element \( (d, c_1, \ldots, c_n) \) of the lattice

\[ \Sigma = \left\{ (d', c_1', \ldots, c_n') \in \mathbb{Z}_{\geq 0}^{n+1}: c_i' \geq -d\alpha_i \text{ for all } i \text{ and } \sum_{i=1}^{n} c_i' a_i = \sum_{i=1}^{n} c_i' b_i = 0 \right\}. \]

In order to determine a generating set for \((R_D)_d\), it suffices to find the extremal rays of \( \Sigma \). To do this, we extend the method of O’Dorney [15, Theorem 8]. We first consider the sub-cone \( \Sigma_1 \subset \Sigma \) given by

\[ \Sigma_1 = \left\{ (d, c_1, \ldots, c_n) \in \mathbb{Z}_{\geq 0}^{n+1}: c_i \geq -d\alpha_i \text{ for all } i \text{ and } \sum_{i=1}^{n} c_i(a_i + b_i) = 0 \right\}, \]

which has extremal rays given by

\[ \epsilon_i := \left( 1, -\alpha_1, \ldots, -\alpha_{i-1}, \frac{\sum_{j \neq i} \alpha_j (a_j + b_j)}{a_i + b_i}, -\alpha_{i+1}, \ldots, -\alpha_n \right). \]

for \( 1 \leq i \leq n \).

Let \( \Sigma_1 \otimes \mathbb{Q} \) be the \( \mathbb{Q}_{\geq 0} \) span of \( \epsilon_1, \ldots, \epsilon_n \). We can intersect \( \Sigma_1 \otimes \mathbb{Q} \) with the hyperplane \( H := V(\sum_{i=1}^{n} a_i x_i) \) to get the subspace \( \Sigma \otimes \mathbb{Q} = H \cap \{ \Sigma_1 \otimes \mathbb{Q} \} \). Then, the extremal rays of \( \Sigma \) are precisely the extremal rays of \( \Sigma \otimes \mathbb{Q} \).

The extremal rays of \( \Sigma \otimes \mathbb{Q} \) can be represented by points lying only on the edges \( \overline{e_i e_j} \). The extremal rays are given by multiples of those \( \epsilon_i \)’s which are contained in \( H \) together with intersection points \( e_{i,j} \) which can be expressed as \( H \cap \overline{e_i e_j} \), where \( i \neq j \) and \( e_{i,j} \notin H \). Note that \( e_{i,j} \) is only defined in the case \( \#(H \cap \overline{e_i e_j}) = 1 \).

From this geometric description of the extremal rays, we can write the extremal rays algebraically as follows. For \( i \in T_+(D) \), define \( e_i \in \mathbb{k}[\Sigma] \) in degree

\[ d_i = \ell_i \gcd(a_i, b_i) \]

by

\[ e_i := d_i e_i. \]
For \( i \in T_+(D) \) and \( j \in T_+(D) \), with \( i < j \), define \( e_{i,j} \in k[\Sigma] \) in degree
\[
d_{i,j} = \ell_{i,j}(a_ib_j - a_jb_i)
\]
by
\[
e_{i,j} := \frac{a_j \sum_{k \neq i,j} d_{i,j} \alpha_k b_k - b_j \sum_{k \neq i,j} d_{i,j} \alpha_k a_k}{a_i b_j - a_j b_i} e_i + \frac{a_i \sum_{k \neq i,j} d_{i,j} \alpha_k b_k - b_i \sum_{k \neq i,j} d_{i,j} \alpha_k a_k}{a_i b_j - a_j b_i} e_j.
\]

Since these \( e_i \) are multiples of \( e_i \) and these \( e_{i,j} \) are points of intersection of \( H \) with \( \sum \), such that neither \( e_i \) nor \( e_j \) are contained in \( H \), these form a set of extremal rays of \( \Sigma \).

Thus, Proposition 2.11 implies that \( R_D \) is generated in degrees less than the sum of the degrees of the \( e_i \) and \( e_{i,j} \), which is
\[
\rho = \sum_{i \in T_+(D)} \gcd(a_i, b_i)\ell_i + \sum_{i \in T_+(D), j \in T_+(D)} (a_i b_j - a_j b_i)\ell_{i,j}.
\]

Let \( w_1, \ldots, w_r \) be the generators of \( R_D \) in degrees less than \( \rho \) (as given by Lemma 3.2), and let \( \phi \) be the surjection \( k[w_1, \ldots, w_r] \to R_D \). As in Section 2, we can factor \( \phi \) through the semigroup ring
\[
k[\Sigma] = \left\langle u^d z_1^{c_1} \cdots z_n^{c_n} : c_i \geq -d\alpha_i, \sum_{i=1}^n a_i c_i = \sum_{i=1}^n b_i c_i \right\rangle,
\]
by
\[
\begin{align*}
\kappa[\Sigma] &\xrightarrow{\chi} k[\Sigma] \xrightarrow{\psi} R_D \\
w_i &\xrightarrow{u^d_i z_i^c_1} \cdots \xrightarrow{u^d_i z_i^c_n} \cdots \xrightarrow{u^d_i f_1^{c_1} \cdots f_n^{c_n}}.
\end{align*}
\]

By Lemma 2.14, we can bound the degree of generation of \( \ker \chi \) below \( 2\rho \). Finally, we calculate the degree of generation of \( \psi \):

**Lemma 3.3.** Let \( \rho \) be as in Equation (3.1). Then, \( \ker \psi \) is generated in degrees less than
\[
\tau := \rho + \max \left( \max_{i \in T_+} (\ell_i \gcd(a_i, b_i)), \max_{i,j \in T_+} (\ell_{i,j}(a_i b_j - a_j b_i)) \right).
\]

**Proof.** We first claim that there exist \( u^{d_i} z_i^\beta_1, \ldots, u^{d_i} z_i^\beta_n \in k[uz_1, uz_2, uz_3, uz_4] \) such that \( \ker \psi \) has relations of the form
\[
u^d(z_i - \beta_i) \prod_{j=1}^n z_j^{c_j}
\]
lying in some degree \( d \in \mathbb{N} \) with \( c_j \geq -\alpha_j d \) (for all \( j \)) satisfying \( a_i + \sum_{j=1}^n a_j c_j = 0 \) and \( b_i + \sum_{j=1}^n b_j c_j = 0 \). Specifically, \( \beta_i \) is the polynomial \( \beta_i(z_1, z_2, z_3, z_4) \) so that \( \beta_i(z_1, z_2, z_3, z_4) - z_i \in \ker \psi \). Such an element \( \beta \) exists and is unique because rational functions whose numerators are polynomials in \( f_1, f_2, f_3, f_4 \) form a basis.
of all rational functions in \( \mathbb{P}_2 \). Furthermore, these generate all relations, since they allow us to reduce any monomial \( u^d \prod_{i=1}^n z_j^{c_i} \) to the canonical form where \( r_j = -\lceil d \alpha_j \rceil \) whenever \( j > 4 \). To bound the degree of generation of these relations, we bound the degree of generation of the ideal \( (\beta_i - z_i) \cap \ker(\psi) \) for each \( i \).

For the remainder of this proof: we fix \( i \in \{1, \ldots, n\} \) and fix a relation of the form \( u^d \prod_{i=1}^n z_j^{c_i} \) as we seek to bound the degree of generation of the ideal \( (\beta_i - z_i) \cap \ker(\psi) \). Note that there are no relations for \( i \in \{1, 2, 3, 4\} \) as then \( \beta_i - z_i = 0 \in \mathbb{Z}^n \). Thus we restrict attention to \( i \geq 5 \). Our goal is to show that if \( u^d (\beta_i - z_i) \prod_{i=1}^n z_j^{c_i} \) has sufficiently high degree, then there is another relation dividing it. We do so by considering the lattice points corresponding to the monomials appearing in the relation \( u^d (\beta_i - z_i) \prod_{i=1}^n z_j^{c_i} \), and finding a fixed \( \lambda \in \Sigma \) that we can simultaneously factor out of all monomials.

Consider a relation \( u^d (\beta_i - z_i) \prod_{i=1}^n z_j^{c_i} \) and let it correspond to the lattice point \( \sigma := (d, c_1, \ldots, c_{i-1}, c_i + 1, c_{i+1}, \ldots, c_n) \in \Sigma \). Then we can write \( \sigma \) as a sum of \( s_j \)’s for \( j \in T_+ \) and \( s_j \)’s for \( j \not\in T_+ \); for convenience, define \( d_j := \deg_e(c_j) \) (when it exists) and let the \( j \)th component of \( \sigma \) be \( -\alpha_i d_j + \kappa_j \) for some \( \kappa_j \in \mathbb{Z} \). Also, let \( d_{j,k} := \deg_e(c_j) \) (when it exists) and let the \( j \)th component of \( \sigma \) be \( -\alpha_k d_{j,k} + \kappa_j' \) for \( \kappa_j' \in \mathbb{Z} \).

Since \( u^d (\beta_i - z_i) \prod_{i=1}^n z_j^{c_i} \) is a relation, each monomial of it must be an element of \( \Sigma \). This implies that \( s_i \kappa_i \geq 1 \), \( \sum_{j \in T_+} s_i j \kappa_j'_{i,j} \geq 1 \), and \( \sum_{j \in T_+} s_i j \kappa_j''_{i,j} \geq 1 \) if \( i \in T_+ \), \( i \in T_+ \), and \( i \in T_+ \), respectively.

If \( i \in T_+ \) define \( r_i := \lambda_i \). If \( i \in T_+ \) choose \( r_i \) such that \( \sum_{j \in T_+} r_{i,j} \kappa_{i,j} \geq 1 \); similarly, if \( i \in T_+ \) choose \( r_{i,j} \) such that \( \sum_{j \in T_+} r_{i,j} \kappa_{i,j} \geq 1 \). For \( j \neq i \), define \( r_j := 0 \). For all pairs \( (j, k) \) so that \( j \neq i \) and \( k \neq i \) define \( r_{j,k} := 0 \). Define \( E \) by

\[
E := \sum_{j \in T_+} (s_j - |s_j - r_j|) c_j + \sum_{j \in T_+} \sum_{k \in T_+} (s_j, k - |s_j - r_j|, k) c_{j,k}.
\]

Note that

\[
\deg(E) \leq \rho + \begin{cases} \ell_i \gcd(a_i, b_i) & \text{if } i \in T_+ \\ \max_{j \in T_+} (\ell_{i,j}(a_i b_j - a_j b_i)) & \text{if } i \in T_+ \\ \max_{j \in T_+} (\ell_{i,j}(a_i b_j - a_j b_i)) & \text{if } i \in T_+ 
\end{cases}
\]

where \( \rho \) is as in Equation (3.1). To obtain the bound given in Equation (3.3), the \( \rho \) term corresponds to the sums of fractional parts of \( s_j - r_j \)’s and \( s_j, k - r_j, k \)’s whereas the second term corresponds to the sums of \( r_j \)’s and \( r_j, k \)’s (noting that in Equation 6.2 \( s_j - |s_j - r_j| = r_j + \text{frac}(s_j - r_j) \)).

Define

\[
\lambda := \sigma - E = \sum_{j \in T_+} (|s_j - r_j|) c_j + \sum_{j \in T_+} \sum_{k \in T_+} (|s_j, k - r_j, k|) c_{j,k} \in \Sigma.
\]

Let \( M_i \) be the set of monomials terms of \( \beta_i = \beta_i(z_1, \ldots, z_4) \). Let \( \mu = \prod_{j=1}^4 z_j^{h_j} \in M_i \) and consider the lattice point

\[
\sigma_\mu = (d, c_1 + h_1, \ldots, c_4 + h_4, c_5, \ldots, c_n).
\]

where \( d = \deg \sigma \). Define

\[
E_\mu = \sigma_\mu - \lambda.
\]
From the definitions, $E_\mu$ lies in $\Sigma$ and has the same degree as $E$.

By construction, $E - \sum_{\mu \in M} E_\mu \in \ker \psi$ and divides $u^d(z_1 - \beta_i) \prod_{j=1}^n z_j^{e_{ij}}$. Furthermore, we have already bounded $\deg(E)$ in Equation (3.3). Finally, recall $\ker \psi$ is generated by relations of the form $u^d(z_1 - \beta_i) \prod_{j=1}^n z_j^{e_{ij}}$ as $i$ ranges between 1 and $n$. Thus, taking the maximum over all $i$ of our bound in Equation (3.3), we see $\ker \psi$ is generated in degrees at most

$$\tau = \rho + \max \left( \max_{i \in T_+} (\ell_i \gcd(a_i, b_i)), \max_{i \in T_+} (\ell_{i,j} (a_i b_j - a_j b_i)) \right) \leq 2\rho. \tag{3.3}$$

By combining the above results, we get our main theorem bounding the generator and relation degrees of the canonical ring of $\mathbb{Q}$-divisors on Hirzebruch surfaces.

**Theorem 3.4.** Let $D = \sum_{i=1}^n \alpha_i D_i \in \mathbb{Q} \otimes \mathbb{Z}$ Div $\mathbb{F}_m$ where $\alpha_i = \frac{f_i}{k_i} \in \mathbb{Q}$ is written in reduced form. Write $\ell_i := \ell_m h_{i1} (k_h)$. Let $u, v, z, w$ be the coordinates for the Hirzebruch surface $\mathbb{F}_m$, as described at the beginning of Section 3 and suppose that $\{f_1, \ldots, f_n\}$ contains two independent linear polynomials in $u, v$ and two independent linear polynomials in $w, x$ (with corresponding $\alpha_j$ possibly zero). Recall $T_\nu, T_\tau, \text{ and } T_\tau$ as given in Definition 3.1 and let each $D_i = V(f_i)$ where $f_i \in O(a_i, b_i)$.

Then $R_D$ is generated in degrees at most

$$\rho = \sum_{i \in T_+ (D)} \gcd(a_i, b_i) \ell_i + \sum_{j \in T_+ (D)} (a_i b_j - a_j b_i) \ell_{i,j}$$

with relations generated in degrees at most $2\rho$.

**Proof.** The generation degree bound is as stated in Lemma 3.2. By Proposition 2.13 the degree of generation of $\ker \phi$ is at most the maximum of the generation degrees of $\ker \chi$ and $\ker \psi$, giving us the desired relations bound. The bound on $\ker \chi$ follows from Lemma 2.14 and the bound on $\ker \psi$ follows from Lemma 3.3. \hfill $\square$

### 4. Further Questions

Recall that every minimal rational surface is either isomorphic to $\mathbb{P}^2$ or $\mathbb{F}_m$ for some $m \geq 0, m \neq 1 \text{ [EH87].}$ By Theorems 1.3 and 1.5 we have given bounds for the generators and relations of arbitrary generalized canonical rings on any minimal rational surface. A natural extension of our results is the following.

**Question 4.1.** Can we describe generators and relations of $R_D$ for a divisor $D$ on an arbitrary rational surface $X$?

Every rational surface can be obtained from a minimal rational surface by a sequence of blow-ups [EH87]. Therefore, to answer Question 4.1 affirmatively, it suffices to bound the degree of generators and relations of the generalized canonical ring of a divisor on a blow-up of a given surface in terms of the generalized canonical rings of some associated divisors that given surface.

Another direction to generalize the work in this paper would be to try to express generalized canonical rings of $\mathbb{Q}$-divisors on $X \times Y$ in terms of those on $X$ and $Y$. In this paper, we bounded the degrees of presentations on generalized canonical rings on $\mathbb{P}^1 \times \mathbb{P}^1 \cong \mathbb{F}_0$. Perhaps similar techniques can be used to bound degrees of presentations on generalized canonical rings on $(\mathbb{P}^1)^k$ or more generally on...
$(\mathbb{P}^1)^i \times \cdots (\mathbb{P}^k)^i_k$. One might further try to generalize this to bounding degrees of presentations on bundles over $\mathbb{P}^m$ or on more general products of schemes.

5. ACKNOWLEDGMENTS

We are grateful to David Zureick-Brown for offering great advice on this project, for many useful suggestions on this paper, and for many valuable conversations. We thank Peter Landesman and Shou-Wu Zhang for offering helpful comments and suggestions for this paper. We also thank Ken Ono and the Emory University Number Theory REU for arranging our project and for the great support that we have received. Finally, we would like to acknowledge the support of the National Science Foundation (grant number DMS-1250467).
