Leading Isospin Breaking effects in nucleon and $\Delta$ masses

Simone Romiti

July 2021

Abstract

We present a lattice calculation of the leading corrections to the masses of nucleons and $\Delta$ resonances. These are obtained in QCD+QED at 1st order in the Isospin Breaking parameters $\alpha_{EM}$, the electromagnetic coupling, and $\frac{\hat{m}_d - \hat{m}_u}{\Lambda_{QCD}}$, coming from the mass difference between $u$ and $d$ quarks.

Keywords - Isospin Breaking, QCD+QED, nucleon, $\Delta$

*This work has been submitted to Suplemento de la Revista Mexicana de Física as a proceeding paper for the [HADRON2021] international conference.

1 Introduction

In this work the Leading Isospin Breaking Effects (LIBEs) in the spectrum of nucleons and $\Delta(1232)$ resonances are investigated using the RM123 method [1–3]. Our calculation is done on the lattice, using a mixed action approach with the twisted mass QCD (tmQCD) regularization over the $N_f = 2 + 1 + 1$ European Twisted Mass Collaboration (ETMC) gauge configurations [4]. A purely hadronic scheme is adopted in order to set the scale, tune the counterterms and extrapolate to the physical point. The results found in this work are the following. The uncertainties are only statistical and obtained using the jackknife resampling technique. We obtain

$$M_n - M_p = 1.73(69)\text{MeV},$$

and the Isospin Breaking (IB) mass splittings in the $\Delta(1232)$ quadruplet (see tab. (2))

| $\Delta^-$ | $\Delta^0$ | $\Delta^+$ | $\Delta^{++}$ |
|------------|------------|------------|---------------|
| $1.251(40)$ | $1.247(39)$ | $1.245(39)$ | $1.244(39)$ |

Table 1: Our results for the masses of the 4 lightest $\Delta$ resonances.

| $\Delta^{++} - \Delta^{-}$ | $\Delta^{++} - \Delta^{0}$ | $\Delta^{++} - \Delta^{-}$ | $\Delta^{++} - \Delta^{0}$ |
|-----------------------------|-----------------------------|-----------------------------|-----------------------------|
| $-0.48(26)$                 | $-2.06(38)$                 | $-4.76(55)$                 | $-4.41(50)$                 |

Table 2: Our results for the $\Delta(1232)$ mass splittings.

We also get a prediction for the masses of nucleons,

$$M_n = 0.961(20)\text{GeV},$$
$$M_p = 0.959(20)\text{GeV},$$

and of the $\Delta$ resonances (see tab. (1)).

The paper is organized as follows. In sec. 2 we review the RM123 method and set our notation for the Isospin Breaking Effects (IBEs). In sec. 3 we discuss the systematic effects, the tuning of counterterms and the extrapolations over the ensembles. Finally in sec. 4 we give our conclusions.

2 Leading IB effects on the lattice

At LO in IB we expand the path integral in the IB parameters $\Delta m_{ud} = (m_d - m_u)/2$ and $e^2$, taking into account $O(e^2)$ counterterms from QED diagrams divergences [5].

As we’ll see, at Leading Order (LO) in IB the knowledge of only 2 of them is sufficient to determine the others.

Note that the fine structure constant $\hat{\alpha}_{EM}$ renormalizes at higher orders [2], so that we can safely use the value $\alpha_{EM} = e^2/(4\pi) = 1/137.035999084$ from [6].
for both the physical and critical masses. The Leading Isospin Breaking correction to the mass of an hadron $H$ is then:

$$
\Delta M_H = \left[ e^2 \Delta_{EM} + \sum f a \Delta m_f^{\text{cr}} \Delta_f^C + \sum f a \Delta m_f \Delta_f^M \right] M_H ,
$$

(1)

where the $\Delta_{EM}$ and $\Delta_f^C$ ($x = C, M$) (for a flavor $f$) are the slopes induced by the couplings in front of them: $EM \rightarrow e^2$, $C \rightarrow$ (critical mass), $M \rightarrow$ (physical mass).

At 1st order these are evaluated in isoQCD from the corrections $\Delta^x$ in the euclidean correlators whose isoQCD ground state has mass $M^{(0)}_H$. The mass slope’s effective curve is:

$$
\Delta^x M(t) = -\partial_t \left[ \Delta^x C_H(t)/C^{(0)}_H(t) \right] ,
$$

(2)

where $\partial_t f(t) = f(t+1) - f(t)$ (in lattice units). In this work we extract the mass slopes fitting these curves to a constant in their plateaus.

We can then write the LIBEs in terms of Feynman diagrams reading $\Box$ for mesons and easily extending $\Box$ for baryons. For the latter we set a shorthand notation for the slopes $\Delta^x C_H^{(i)}$ $\Box$, where $x$ corresponds to the current insertion(s) and $i = 1, 2, 3$ is the quark propagator index. When $x = M, C$ we insert the scalar or pseudoscalar current respectively on the $i$-th quark leg, while $x = \text{self}$ comes from its electromagnetic self-energy. When $x = \text{exch}$ we exchange a photon between the 2 quarks different from the $i$-th one. We define the ratios $R_{H,x} = -\partial_t[\Delta^x C_H^{(i)} / C^{(0)}_H]$ for $x \in \{M, C, \text{self, exch}\}$ and $R_{H,ij} = -\partial_t[\Delta^x C_H^{(i,f)} / C^{(0)}_H]$, where the latter comes from the exchange of a photon between the $i$-th quark with a quark loop of flavor $f$ (from the sea).

The LIBEs for nucleons then assume the following form:

$$
\Delta M_n = -\Delta m_u R_{N_1}^M + \Delta m_d R_{N_2}^M - \Delta m_s R_{N_3}^M \\
+ \Delta m_u^{\text{cr}} R_{N_1}^C + \Delta m_d^{\text{cr}} R_{N_2}^C + \Delta m_s^{\text{cr}} R_{N_3}^C \\
+ q_u^2 R_{N_1}^{\text{self}} + q_d^2 R_{N_2}^{\text{self}} + q_s^2 R_{N_3}^{\text{self}} + q_u q_d R_{N_2}^{\text{exch}} + q_u q_s R_{N_3}^{\text{exch}} + q_d q_s R_{N_1}^{\text{exch}} \\
+ \sum_{f \in \{\text{sea}\}} q_{uf} \left[ q_u R_{N_1}^{\text{loop}} + q_d R_{N_2}^{\text{loop}} + q_s R_{N_3}^{\text{loop}} \right] \\
+ \text{[isosymm. vac. pol. diag.]} ,
$$

(3)

and $\Delta M_p$ is found via the exchange symmetry $u \leftrightarrow d$. For the $\Delta s$ we have:

$$
\Delta M_{\Delta^{++}} = -\Delta m_u [R_{\Delta_1}^M + R_{\Delta_2}^M + R_{\Delta_3}^M] + \Delta m_u^{\text{cr}} [R_{\Delta_1}^C + R_{\Delta_2}^C + R_{\Delta_3}^C] \\
+ q_u^2 [R_{\Delta_1}^{\text{self}} + R_{\Delta_2}^{\text{self}} + R_{\Delta_3}^{\text{self}} + R_{\Delta_1}^{\text{exch}} + R_{\Delta_2}^{\text{exch}} + R_{\Delta_3}^{\text{exch}}] \\
+ \sum_{f \in \{\text{sea}\}} q_{uf} \left[ R_{\Delta_1}^{\text{loop}} + R_{\Delta_2}^{\text{loop}} + R_{\Delta_3}^{\text{loop}} \right] \\
+ \text{[isosymm. vac. pol. diag.]} ,
$$

(4)

3This formula holds in absence of backward signals, namely for baryonic correlators with given parity $\Box \Box$, while for mesons it gets slightly modified $\Box$.

4The baryonic correlators $C_H$ are built from the interpolators of $\Box$. 
\[ 3\Delta M_{\Delta^+} = -\Delta m_d R^M_\Delta - \Delta m_u R^M_\Delta - \Delta m_u R^M_\Delta - \Delta m_u R^M_\Delta \]
\[ + \Delta m_d^{(cr)} R^C_\Delta + \Delta m_u^{(cr)} R^C_\Delta + \Delta m_u^{(cr)} R^C_\Delta \]
\[ + q_d R^\text{self}_\Delta + q_d R^\text{self}_\Delta + q_d R^\text{self}_\Delta + q_d R^\text{self}_\Delta + q_d R^\text{self}_\Delta + q_d R^\text{self}_\Delta \]
\[ + \sum_{f \in \{\text{sea}\}} q_f \left[ q_d R^{\text{loop}}_{\Delta f} + q_u R^{\text{loop}}_{\Delta f} + q_u R^{\text{loop}}_{\Delta f} \right] \]
\[ (5) \]
\[ + \{ (d, u, u) \rightarrow (u, d, u) \} + \{ (d, u, u) \rightarrow (u, u, d) \} \]
\[ \Delta M_{\Delta^-} \text{ and } \Delta M_{\Delta^0} \text{ have the same form of } \Delta M_{\Delta^{++}} \text{ and } \Delta M_{\Delta^+} \text{ respectively, found via the flavor exchange } u \leftrightarrow d. \text{ It’s easy to verify that at LO only 2 of the 4 } \Delta \text{ mass splittings are independent. The IB correction to } M_{\Omega^-} \text{ is like } \Delta M_{\Delta^{++}}, \text{ obtained replacing } u \rightarrow s \text{ (and the } \Delta \text{ interpolator with the } \Omega \text{’s)}. \]

3 Systematics, tuning and extrapolations

In this work we neglect the disconnected isosymmetric vacuum polarization diagrams [10]. We also work in the electroquenched approximation [11], so that all the diagrams with photons attached to quark loops vanish. We introduce QED in a non-compact way [12], with the QED regularization for the photon propagator [13-14]. The universal QED Finite Volume Effects (FVEs) in the hadronic spectrum [17] are corrected for each ensemble, leaving only the structure-dependent FVEs starting from \( O(1/L^3) \).

In tmQCD the presence of IB leads to counterterms to both the critical and physical masses. Analogously to \[ 3 \], the former are tuned using the PCAC Ward Identity requiring to preserve the maximal twist in isoQCD [18] also at \( O(\epsilon^2) \). For an observable \( O \), the quarks masses physical point in isoQCD and QCD+QED is defined by the ratios \( r_s = (2(M_{\pi^+}^2 + M_{\pi^0}^2) - (M_{\pi^+}^2 + M_{\pi^0}^2))/2M_{\Omega^-}^2 \), \( r_{\ell} = (M_{\pi^+}^2 + M_{\pi^0}^2)/2M_{\Omega^-}^2 \) and \( r_p = M_{\pi^+}^2/M_{\Omega^-}^2 \), requiring them to match their experimental values. As a consequence, at the physical point their total IB corrections vanishes. We impose the latter condition at fixed ensemble in order to tune the counterterms \( a\Delta m_{\ell} \).

This allows to evaluate (in the full theory and for each ensemble) any observable \( O \), whose physical point is reached by contraction after the aforementioned extrapolation. The latter is done in separate steps, on the slice \( r_s = \delta_{\text{phys}}^{(\text{exp})} \) of the hyper-surface \( O(r_s, r_{\ell}, L, a) \).

We extrapolate to the physical point, \( L \rightarrow \infty \), and \( a \rightarrow 0 \) with global fits among the ensembles using phenomenological ansätze inspired by LO ChPT [19-21]. The previously mentioned masses \( M_i \) are fitted among the ensembles using the following functional forms:

\[ M_i(L, r_{\ell}, a) = A_i \left[ 1 + \alpha_{EM} \frac{c_3}{L^3} + c_1 a^2 + c_2 r_{\ell} + c_3 a^2 \ell_{\ell}^{3/2} \right] \]
\[ (7) \]

\[ 8 \]

In this work the lattice spacings \( a_{\beta(i)} \) (\( \beta = 1.90, 1.95, 2.10 \), see [2]) are set by the \( \Omega^- \) mass, extrapolating \( a M_{\Omega^-} \) among the ensembles with the polynomial ansätze:

\[ (a M_{\Omega})_i(L, r_{\ell}) = a_{\beta(i)} M_{\Omega}^{\text{exp}} \left[ 1 + c_L \frac{\alpha_{EM}}{L^3} + c_L r_{\ell} + c_L^2 r_{\ell}^2 \right] \]
\[ (6) \]

and setting the extrapolated values equal to \( a_{\beta(i)} M_{\Omega}^{\text{exp}} \). The coefficients \( a_{\beta(i)}, c_L, \ldots \) are free parameters of the fit.
while for the IB mass splittings $\Delta M_i$ we use a simple polynomial ansatz:

$$\Delta M_i(L, r_\ell, a) = D_i \left[ 1 + \alpha_{EM} \frac{c^{(i)}_a}{L^3} + d^{(i)}_a a^2 + d^{(i)}_r r_\ell \right],$$  \hspace{1cm} (8)

The coefficients $A_i, c^{(i)}_a, ...$ and $D_i, d^{(i)}_a, ...$ are left as free parameters of the fits. Given the maximal twist (and hence the $O(a)$ improvement), discretization effects start at $O(a^2)$, while the $\sim 1/L^3$ term accounts for the residual structure-dependent QED FVEs in the $a\Delta m_I$ and the masses themselves. Higher orders in $1/L$ and QCD FVEs are found to be numerically negligible at our level of precision.

4 Conclusion

In this work we’ve computed on the lattice the LIBEs in the spectrum of mesons and baryons, getting a prediction for the masses and IB mass splittings of nucleons and the $\Delta(1232)$ resonances. In particular, we note that the full spectrum of the $\Delta(1232)$ quadruplet is not completely determined experimentally yet, motivating its investigation. The values we found are compatible within at most 1.5$\sigma$ with the experimental predictions. This is so despite the approximations introduced in the calculation, indicating that at our level of precision the neglected diagrams are physically suppressed as expected. Their neglect introduce nevertheless systematic effects which can be known only by direct evaluation, and which we aim to include in a future work.
