Spherical homogeneous spaces of minimal rank

N. Ressayre

Abstract. Let $G$ be a complex connected reductive algebraic group and $G/B$ denote the flag variety of $G$. A $G$-homogeneous space $G/H$ is said to be spherical if $H$ has a finite number of orbits in $G/B$. A class of spherical homogeneous spaces containing the tori, the complete homogeneous spaces and the group $G$ (viewed as a $G \times G$-homogeneous space) has particularly nice properties. Namely, the pair $(G, H)$ is called a spherical pair of minimal rank if there exists $x$ in $G/B$ such that the orbit $H.x$ of $x$ by $H$ is open in $G/B$ and the stabilizer $H_x$ of $x$ in $H$ contains a maximal torus of $H$. In this article, we study and classify the spherical pairs of minimal rank.

1 Introduction

Let $G$ be a complex connected reductive algebraic group. Let $\mathcal{B}$ denote the flag variety of $G$. Let $H$ be an algebraic subgroup of $G$ which has a finite number of orbits in $\mathcal{B}$; the subgroup $H$ and the homogeneous space $G/H$ are said to be spherical.

In this article, we study and classify a class of spherical homogeneous spaces containing the tori, the complete homogeneous spaces and the group $G$ viewed as a $G \times G$-homogeneous space. Namely, the pair $(G, H)$ is called a spherical pair of minimal rank if there exists $x$ in $\mathcal{B}$ such that the orbit $H.x$ of $x$ by $H$ is open in $\mathcal{B}$ and the stabilizer $H_x$ of $x$ in $H$ contains a maximal torus of $H$. In [Kno95] the rank $\text{rk}(G/H)$ of the homogeneous space $G/H$ is defined. Moreover, we have $\text{rk}(G/H) \geq \text{rk}(G) - \text{rk}(H)$ (where $\text{rk}(G)$ and $\text{rk}(H)$ denotes the ranks of the groups $G$ and $H$) with equality if and only if $(G, H)$ is of minimal rank. This explains the name. The spherical pairs $(G, H)$ of minimal rank such that $H$ is a symmetric subgroup of $G$ firstly appear in [Bri04]. During the redaction of this article the compactifications of the spherical homogeneous spaces of minimal rank was studied in [Tch05] and [BJ06].

Let us state our main result. Propositions 3.1, 3.2 and 4.2 reduce the classification to the special case when $G$ is semi-simple adjoint and $H$ is simple. Indeed, any spherical pair of minimal rank is obtained from special ones and toric ones by products, finite covers and parabolic inductions. Next, we prove

**Theorem A** The spherical pairs $(G, H)$ of minimal rank with $G$ semi-simple adjoint and $H$ simple are:

(i) $G = H$.

(ii) $H$ is simple and diagonally embedded in $G = H \times H$.

(iii) $(\text{PSL}_{2n}, \text{PSp}_{2n})$ with $n \geq 2$.

(iv) $(\text{PSO}_{2n}, \text{SO}_{2n-1})$ with $n \geq 4$. 

1
We denote by $H(B)$ the set of the $H$-orbit closures in $B$. If $H = P$ is a Borel subgroup of $G$, the elements of $H(B)$ are the famous Schubert varieties. Most of combinatorial and geometric properties of the Schubert varieties cannot be generalized to the elements of $H(G/B)$ if $H$ is only spherical. However, if $H$ is of minimal rank the elements of $H(G/B)$ have nice properties. Let us give details.

The Weyl group $W$ of $G$ acts transitively on the set of Schubert varieties; this action parametrizes these varieties by $W/W_P$. In general, F. Knop has defined in [Kno95] an action of $W$ in $H(B)$; but, it seems to be difficult to deduce a parametrization of $H(B)$ from this action. We show in Proposition 2.1 that $G/H$ is of minimal rank if and only if the action of $W$ is transitive on $H(B)$. In this case, the isotropy groups are isomorphic to the Weyl group $W_H$ of $H$; and, $W/W_H$ parametrizes $H(B)$.

The Schubert varieties are normal; but, in general elements of $H(B)$ are not normal (see [Bri01] or [Pin01] for examples). By a result of Brion, if $G/H$ is of minimal rank, the elements of $H(B)$ are normal.

In [Kno95], F. Knop also defined an action of a monoid $\tilde{W}$ (constructed from the generators of $W$) on $H(B)$. Moreover, the inclusion defines an order on $H(B)$ which generalizes the Bruhat order for the Schubert varieties. The description of the Bruhat order from the action of $\tilde{W}$ is well known as the cancellation lemma. In general, no such description of this order is known. Corollary 2.1 is a cancellation lemma in the minimal rank case.

The number of Schubert varieties of dimension $d$ equal those of the codimension $d$. In Proposition 2.3 we show such a symmetry property of $H(B)$ for any spherical pair $(G, H)$ of minimal rank.

Let us explain another important motivation for this work. Let $T$ be a maximal torus of $G$ and $X$ be a $G$-equivariant embedding of a spherical homogeneous space $G/H$ of minimal rank. In Proposition 2.4, we show that for all fixed point $x$ of $T$ in $X$, $G.x$ is complete. This property seems to play a key role in several works about the embeddings of $G \times G/G$ (see for example, [Tch02]).

In Section 2, we study the properties of $H(B)$ and of the toroidal embeddings of $G/H$ for the spherical pairs $(G, H)$ of minimal rank. This allows us to give several characterizations of the minimal rank property. In Section 3, we reduce the classification to the case when $G$ and $H$ are semisimple. In Section 4, we classify such pairs by associating to $(G, H)$ an involution on the vertices of the Dynkin diagram of $G$.

2 Equivalent definitions and first properties

2.1 Minimal rank and orbits of $H$ in $B$

2.1.1 — Let us fix some general notation. If $X$ is a variety, $\dim(X)$ denotes the dimension

\((v) (SO_7, G_2)\).

\((vi) (E_6, F_4)\).
of $X$. It $x$ belongs to $X$, $T_x X$ denotes the Zariski-tangent space of $X$ at $x$. If $\Gamma$ is an algebraic group a $\Gamma$-variety $X$ is a variety endowed with an algebraic action of $\Gamma$. Let $\Gamma$ be an affine algebraic group and $X$ be a $\Gamma$-variety. For $x$ a point in $X$, we denote by $\Gamma_x$ the isotropy group of $x$ and by $\Gamma.x$ its orbit. We denote by $X^\Gamma$ the set of fixed point of $\Gamma$ in $X$. We denote by $\Gamma^u$ the unipotent radical of $\Gamma$.

2.1.2 — Let us recall that $G$ is a connected complex reductive group, $\mathcal{B}$ its flag variety, $H$ a spherical subgroup of $G$ and $\mathcal{H}(\mathcal{B})$ the set of the $H$-orbit closures in $\mathcal{B}$. If $V$ belongs to $\mathcal{H}(\mathcal{B})$, we denote by $V^\circ$ the unique open $H$-orbit in $V$.

We recall the definition of [Res04] of a graph $\Gamma(G/H)$ whose vertices are the elements of $\mathcal{H}(\mathcal{B})$. The original construction of $\Gamma(G/H)$ due to M. Brion is equivalent but very slightly different (see [Bri01]).

Consider the set $\Delta$ of conjugacy classes of minimal non solvable parabolic subgroups of $G$. If $\alpha$ belongs to $\Delta$, we denote by $\mathcal{P}_\alpha$ the $G$-homogeneous space with isotropy $\alpha$. Then, there exists a unique $G$-equivariant map $\phi_\alpha : \mathcal{B} \rightarrow \mathcal{P}_\alpha$ which is a $\mathbb{P}^1$-bundle.

Let $V \in \mathcal{H}(\mathcal{B})$ and $\alpha \in \Delta$. We assume that the restriction of $\phi_\alpha$ to $V^\circ$ is finite and we denote its degree by $d(V, \alpha)$. Then, $\phi_\alpha^{-1}(\phi_\alpha(V))$ is an element denoted $V'$ of $\mathcal{H}(\mathcal{B})$; in this case, we say that $\alpha$ raises $V$ to $V'$. One of the three following cases occurs.

- Type $U$: $H$ has two orbits in $\phi_\alpha^{-1}(\phi_\alpha(V^\circ))$ ($V^\circ$ and $V'^\circ$) and $d(V, \alpha) = 1$.
- Type $T$: $H$ has three orbits in $\phi_\alpha^{-1}(\phi_\alpha(V^\circ))$ and $d(V, \alpha) = 1$.
- Type $N$: $H$ has two orbits in $\phi_\alpha^{-1}(\phi_\alpha(V^\circ))$ ($V^\circ$ and $V'^\circ$) and $d(V, \alpha) = 2$.

DEFINITION. Let $\Gamma(G/H)$ be the oriented graph with vertices the elements of $\mathcal{H}(\mathcal{B})$ and edges labeled by $\Delta$, where $V$ is joined to $V'$ by an edge labeled by $\alpha$ if $\alpha$ raises $V$ to $V'$. This edge is simple (resp. double) if $d(V, \alpha) = 1$ (resp. 2). Following the above cases, we say that an edge has type $U$, $T$ or $N$.

2.1.3 — Let us fix a Borel subgroup $B$ of $G$. Let $Y$ be a $B$-variety. The character group $\mathcal{X}(Y)$ of $Y$ is the set of all characters of $B$ that arise as weights of eigenvectors of $B$ in the function field $\mathbb{K}(Y)$. Then $\mathcal{X}(Y)$ is a free abelian group of finite rank $\text{rk}(Y)$, the rank of $Y$ (see [Kno95]). It is well known that a $B$-orbit $\mathcal{O}$ is isomorphic as a variety to $\mathbb{K}^l \times (\mathbb{K}^*)^r$ where $r = \text{rk}(\mathcal{O})$ and $l = \dim(\mathcal{O}) - \text{rk}(\mathcal{O})$.

If $V$ belongs to $\mathcal{H}(\mathcal{B})$, we set:

$$V_H = \{gH/H : g^{-1}B/B \in V\}.$$  

Then, $V_H$ is a $B$-orbit closure in $G/H$. Moreover, the map $V \mapsto V_H$ is a bijection from $\mathcal{H}(\mathcal{B})$ onto the set of the $B$-orbit closures in $G/H$. The rank of $V_H$ is also denoted by $\text{rk}(V)$ and called the rank of $V$.

2.1.4 — Let $T$ be a maximal torus of $B$. Let $W$ denote the Weyl group of $T$. Every $\alpha$ in $\Delta$ has a unique representative $P_\alpha$ which contains $B$. Moreover, there exists a unique $s_\alpha$ in $W$ such that $B s_\alpha B$ is dense in $P_\alpha$; and this $s_\alpha$ is a simple reflexion of $W$. The map, $\Delta \rightarrow W, \alpha \mapsto s_\alpha$ is a bijection from $\Delta$ onto the set of simple reflexions of $W$.
F. Knop defined in [Kno95] an action of $W$ on the set $H(B)$ by describing the action of the $s_\alpha$, for any $\alpha \in \Delta$:

- **Type $U$:** $s_\alpha$ exchanges the two vertices of an edge of type $U$ labeled by $\alpha$.
- **Type $T$:** If $\alpha$ raises $V_1$ and $V_2$ to $V$, then $s_\alpha V_1 = V_2$ and $s_\alpha V = V$.
- **Type $N$:** $s_\alpha$ fixes the two vertices of a double edge labeled by $\alpha$.
- $s_\alpha$ fixes all others vertices of $\Gamma(G/H)$.

2.1.5 — We can now characterize the spherical pairs of minimal rank in terms of $H(B)$:

**Proposition 2.1** With above notation, the following are equivalent:

(i) There exists $x \in B$ such that $H.x$ is open in $B$ and $H_x$ contains a maximal torus of $H$.

(ii) $\text{rk}(G) - \text{rk}(H) = \text{rk}(G/H)$.

(iii) All the elements of $H(B)$ have same rank.

(iv) All the edges in $\Gamma(G/H)$ have type $U$.

(v) $W$ acts transitively on $\Gamma(G/H)$.

If $(G, H)$ satisfies these properties, we say that $(G, H)$ is of minimal rank.

**Proof.** The equivalence between the two first assertions follows from [Res05, Corollary 3.1].

Let us recall some properties of the graph $\Gamma(G/H)$ from [Bri01]. If $\alpha$ raises $V$ to $V'$ by an edge of type $U$ (resp. $T$ or $N$) then $\text{rk}(V') = \text{rk}(V)$ (resp. $\text{rk}(V') = \text{rk}(V) + 1$). Moreover, all $V$ in $H(B)$ is joined to $B$ by an increasing path in $\Gamma(G/H)$ (property of connectedness). Finally, the rank of a closed $H$-orbit in $B$ equals $\text{rk}(G) - \text{rk}(H)$.

Now, one easily checks the equivalence between Assertions (ii), (iii), (iv) and (v). □

2.1.6 — Let $(G, H)$ be a spherical pair of minimal rank. Then, the elements of $H(B)$ can be parametrized. Indeed, let $W_0$ be the stabilizer of $B$ for the action of $W$. In [Res05], it is shown that $W_0$ is isomorphic to the Weyl group $W_H$ of $H$. Moreover, Proposition 2.1 shows that the Knop’s action gives a bijection between $W/W_0$ and $H(B)$. In particular, we have: $|H(B)| = \frac{|W|}{|W_H|}$, where $|E|$ denotes the cardinality of the finite set $E$.

Each orbit closure $V$ of $H$ in $B$ is multiplicity-free in the sense of [Bri01]. In particular, by [Bri01, Theorem 5] $V$ is normal.

2.1.7 — In this paragraph, we are interested in reading the generalized Bruhat order off the graph $\Gamma(G/H)$. Let us start by showing the following nice property of this graph:

**Proposition 2.2** There exists a unique closed orbit of $H$ in $B$ and it is the only minimal element of $\Gamma(G/H)$. 
Proof. Let \( V_0 \) be a closed orbit of \( H \) in \( \mathcal{B} \). Let \( \mathcal{H}_0 \) be the set of the \( H \)-orbit closures in \( \mathcal{B} \) linked with \( V_0 \) by an oriented path in \( \Gamma(G/H) \). It is sufficient to prove that \( \mathcal{H}_0 = \mathcal{H}(\mathcal{B}) \).

We assume that \( \mathcal{H}(\mathcal{B}) - \mathcal{H}_0 \) is not empty. Since \( \mathcal{B} \) belongs to \( \mathcal{H}_0 \) and all the orbits are joined to \( \mathcal{B} \) by an oriented path, there exists \( Z \in \mathcal{H}(\mathcal{B}) - \mathcal{H}_0 \) and \( \alpha \in \Delta \) such that \( \alpha \) raises \( Z \) to an element \( Z' \) of \( \mathcal{H}_0 \) (it is sufficient to take \( Z \) of maximal dimension in \( \mathcal{H}(\mathcal{B}) - \mathcal{H}_0 \)). Let us fix such a pair \((Z, \alpha)\) such that \( Z \) is of minimal dimension.

Since \( Z' \neq V_0 \), there exists \( \beta \in \Delta \) and \( Y \in \mathcal{H}_0 \) such that \( \beta \) raises \( Y \) to \( Z' \). Since the edges of \( \Gamma(G/H) \) are of type \( U \) and \( Y \neq Z \), we have \( \beta \neq \alpha \).

Using [Bri01, Lemma 3], one easily checks that one of the two following graphs is a subgraph of \( \Gamma(G/H) \):

\[
\begin{array}{c}
\text{Y} & \alpha & \text{Z} \\
\beta & \text{V} & \text{V}' \\
\end{array}
\]

In the first case, \( Z, V' \) and \( V'' \) does not belong to \( \mathcal{H}_0 \). By minimality of the dimension of \( Z \) and by considering \((V'',\beta)\) we deduce that \( V \) does not belong to \( \mathcal{H}_0 \). Now, the pair \((V,\alpha)\) contradicts the minimality of the dimension of \( Z \). A similar argue works in the second case. \( \square \)

Let \( V \) in \( \mathcal{H}(\mathcal{B}) \) and \( V_0 \) denote the unique closed \( H \)-orbit \( \mathcal{B} \). By Proposition 2.2, there exists an increasing path in \( \Gamma(G/H) \) from \( V_0 \) to \( V \). Let \( (\alpha_1, \ldots, \alpha_s) \) be the sequence of the labels of the edges of such a path. Notice that \( s = \dim(V) - \dim(V_0) \). The inclusion relation \( \mathcal{H}(\mathcal{B}) \) can be read off the graph \( \Gamma(G/H) \) by the following cancellation corollary:

**Corollary 2.1** We use above notation and fix \( V' \) in \( \mathcal{H}(\mathcal{B}) \). Set \( k = \dim(V') - \dim(V_0) \). Then, \( V' \subset V \) if and only if there exists \( i_1 < \cdots < i_k \) such that the increasing path starting from \( V_0 \) and with labels \( (\alpha_{i_1}, \ldots, \alpha_{i_k}) \) ends at \( V' \).

**Proof.** Using Proposition 2.2, the proof of [RS90] works here. \( \square \)

2.1.8 — Let \( d_G \) (resp. \( d_H \)) denote the dimension of the complete flag variety of \( G \) (resp. \( H \)). Then, we have the following “symmetry” on the set \( \mathcal{H}(\mathcal{B}) \):

**Proposition 2.3** Here we assume that \( H \) is connected. For all \( 0 \leq \delta \leq d_G - d_H \), the number of elements in \( \mathcal{H}(\mathcal{B}) \) of dimension \( d_G - \delta \) equal those of dimension \( d_H + \delta \).

**Proof.** Consider \( P_G(t) \) and \( P_H(t) \) the Poincaré polynomials of the complete flag varieties of \( G \) and \( H \). By Poincaré duality, they are symmetric polynomials of degrees \( d_G \) and \( d_H \); that is, \( t^{d_G} P_G(1/t) = P_G(t) \) and \( t^{d_H} P_H(1/t) = P_H(t) \).
Consider the following polynomial:

\[ Q(t) = \sum_{V \in H(B)} t^{\dim(V) - d_H}. \]

We claim that \( Q(t) \cdot P_H(t) = P_G(t) \). The claim implies that \( Q(t) \) is symmetric and so the proposition.

Let \( B_H \) denote the flag variety of \( H \). For any \( x \in B \), \( H_x \) is a solvable subgroup of \( H \) containing a maximal torus of \( H \). It follows that \( H_x \) is contained in a Borel subgroup of \( H \); consider \( \varphi_x : H.x \to B_H \) the map induced by this inclusion. Moreover, the fiber \( \varphi_x^{-1}(\varphi_x(x)) \) is isomorphic to an affine space of dimension \( \dim(H.x) - d_H \).

We choose one point in each orbit of \( H \) in \( B \) and consider the associated morphisms \( \varphi_x \). There exists a finitely generated extension \( K \) of \( \mathbb{Q} \) such that \( G, H \), the inclusion of \( H \) in \( G \), the chosen points in \( B \), the morphisms \( \varphi_x \), the isomorphisms between the fibers the \( \varphi_x \) and affine spaces are all defined. By taking an extension if necessary, we may (and shall) also assume that the Schubert cells (for fixed Borel subgroups of \( G \) and \( H \)) of \( B \) and \( B_H \) are defined and isomorphic to affine spaces over \( K \).

Now, we consider a finite quotient \( \mathbb{F}_q \) of \( K \) and the points \( B(\mathbb{F}_q^n) \) of \( B \) over \( \mathbb{F}_q^n \) for all positive integer \( n \). By using the decompositions of \( B \) and \( B_H \) in Schubert cells, one obtain:

\[ |B(\mathbb{F}_q^n)| = P_G(q^n) \quad \text{and} \quad |B_H(\mathbb{F}_q^n)| = P_H(q^n). \]

Now, we count the points in \( B(\mathbb{F}_q^n) \) by using the decomposition in \( H \)-orbits:

\[ |B(\mathbb{F}_q^n)| = \sum_{V \in H(B)} |V(\mathbb{F}_q^n)| = \sum_{V \in H(B)} |B_H(\mathbb{F}_q^n)| \cdot (q^n)^{\dim(V) - d_H} = P_H(q^n) \cdot Q(q^n). \]

The claim follows.

\[ \square \]

## 2.2 Minimal rank and toroidal embeddings

**2.2.1** — In this subsection, \((G, H)\) is a spherical pair not necessarily of minimal rank. An **embedding** of \( G/H \) is a pair \((X, x)\) where \( X \) is a normal and irreducible \( G \)-variety and \( x \) is a point of \( X \) such that \( G.x \) is open in \( X \) and \( G_x = H \). Such an embedding is said to be **toroidal** if any irreducible \( B \)-stable divisor of \( X \) which contains a \( G \)-orbit is \( G \)-stable.

**Lemma 2.1** Let \( G/H \) be a spherical homogeneous space (not necessarily of minimal rank). Let \((X, x)\) be a toroidal embedding of \( G/H \) and \( y \) be a point in \( X \).

Then, we have the inequality:

\[ \rk(G/H) + \rk(H) \geq \rk(G.y) + \rk(G_y). \]

In particular, if \( G/H \) is of minimal rank, \( G.y \) is.
Proof. Firstly, we prove that it is sufficient to show the lemma when \( \dim(G.y) = \dim(X) - 1 \). By [BL87, Lemma 2.1.1], since \( X \) is toroidal, there exists \( G \)-orbits \( O_0, \ldots, O_s \) such that \( G.y = O_0 \subset O_1 \subset \cdots \subset O_s = X \) (where \( \overline{O_i} \) denotes the closure of \( O_i \) in \( X \)) and \( \dim(O_{i+1}) = \dim(O_i) + 1 \) for all \( i = 0, \ldots, s - 1 \). For all \( i \) we fix a point \( y_i \) in \( O_i \). Since \( \overline{O_i} \) is normal, we can apply the case when \( \dim(G.y) = \dim(X) - 1 \) to each \( O_i \subset \overline{O_{i+1}} \) showing that:

\[
\text{rk}(G.y_{i+1}) + \text{rk}(G.y_i) \geq \text{rk}(G.y_i) + \text{rk}(G.y_i).
\]

The inequality of the lemma follows.

We now assume that \( \dim(G.y) = \dim(X) - 1 \). Set \( O = G.y \). Consider the linear action of the group \( G_y \) acts on quotient \( T_yX/T_yO \) of \( T_yX \) by \( T_yO \). Since \( X \) is normal, it is smooth at \( y \) and \( T_yX/T_yO \) is a line. So, the action of \( G_y \) defines a character \( \chi : G_y \rightarrow \mathbb{K}^* \).

Let \( T_y \) be a maximal torus of \( G_y \). Let \( S \) denote the neutral component of the kernel of the restriction of \( \chi \) to \( T_y \). We claim that \( S \) has fixed points in \( G.x \). Set \( \Omega = G.x \cup O \); it is open in \( X \) and hence it is a smooth variety. By a result of Bialynicki-Birula, we have \( T_x(\Omega^S) = (T_x\Omega)^S \). In particular, \( \Omega^S \) is not contained in \( O \). This proves the claim.

By the claim, a subgroup conjugated to \( S \) fixes \( x \) and:

\[
\text{rk}(H) \geq \dim(S) = \dim(T_y) - 1 = \text{rk}(G.y) - 1.
\]

Moreover, since \( X \) is toroidal \( \text{rk}(G/H) = \text{rk}(O) + 1 \). The lemma follows. \( \square \)

2.2.2 — The fixed points of a maximal torus of \( G \) in the toroidal embeddings of spherical homogeneous spaces of minimal rank are easy to localize. Indeed, we have:

**Proposition 2.4** Let \((G, H)\) be a spherical pair and \( T \) be a maximal torus of \( G \). The following are equivalent:

(i) \((G, H)\) is of minimal rank.

(ii) There exists a complete toroidal embedding \((X, x)\) of \( G/H \) such that for all \( x \in X^T \) \( G.x \) is complete.

(iii) For all complete toroidal embedding \((X, x)\) of \( G/H \) and for all \( x \in X^T \), \( G.x \) is complete.

**Proof.** We assume that \((G, H)\) is of minimal rank and fix a complete toroidal embedding \((X, x)\) of \( G/H \). Let \( y \in X^T \). Lemma 2.1 shows that \( \text{rk}(G.y) = 0 \); that is \( G.y \) is complete. This proves that Assertion (i) implies Assertion (iii).

Conversely, let \((X, x)\) satisfying Assertion (ii). It remains to prove that \((G, H)\) is of minimal rank.

Let \( \lambda \) be a one-parameter subgroup of \( T \) such that \( T \) is the centralizer of the image of \( \lambda \) (that is, \( \lambda \) is regular) and \( X^\lambda = X^T \) (where \( X^\lambda \) denote the set of fix points of the image of \( \lambda \)). Since \( \lambda \) is regular, the set \( g \in G \) such that \( \lim_{t \to 0} \lambda(t)g\lambda(t^{-1}) \) exists in \( G \) is a Borel subgroup of \( G \) denoted by \( B(\lambda) \). By Proposition 2.1, it is sufficient to prove that for all
y ∈ G.x we have \( \text{rk}(B(\lambda).y) = \text{rk}(G/H) \). This holds by Lemma 2.2 below since the rank of a complete G-orbit equals zero.

\[ \text{Lemma 2.2} \]

Let \((X, x)\) be a complete toroidal embedding of the spherical homogeneous space \(G/H\). Let \(y\) be a point in the open G-orbit in \(X\) Let \(\lambda\) be a regular one-parameter subgroup of \(T\) such that \(X^\lambda = X^T\). Set \(z = \lim_{t \to 0} \lambda(t)y\).

Then, we have:

\[ \text{rk}(G/H) - \text{rk}(B(\lambda).y) = \text{rk}(G.z). \]

**Proof.** Let us introduce some material and notation from [BL87]. There exists a parabolic subgroup \(P\) of \(G\) containing \(T\) such that \(P_z\) is reductive. Let \(Q\) denote the parabolic subgroup of \(G\) containing \(T\) and opposite to \(P\). We have \(G_u z \subset Q_u z\) and there exists a closed subvariety \(A \subset Q_u z\) -stable such that the product in \(G\) induces an isomorphism \(A \times Q_u z \rightarrow Q_u z\).

By [BL87, Lemma 1.1], there exists a locally closed affine normal and irreducible subvariety \(S\) of \(X\) such that \(S \cap G.z = \{z\}\), \(S\) is \(P_z\)-stable and the morphism \(G \times S \rightarrow X\) induced by the action is smooth at \((1, z)\). In particular, we have:

\[ \dim(S) = \dim(G/H) - \dim(G.z) = \text{rk}(G/H) - \text{rk}(G.z). \tag{1} \]

Let \(P \times_P (A \times S)\) denote the quotient of \(P \times A \times S\) by the action of \(P_z\) defined by \(p.(q, a, s) = (qp^{-1}, pap^{-1}, ps)\), where \(p \in P_z\), \((q, a, s) \in P \times A \times S\). The group \(P\) acts naturally on this variety. By [BL87, Theorem 5], the morphism

\[ \Theta : P \times_P (A \times S) \rightarrow X \]

\[(p : (a, s)) \mapsto (pa).s\]

is an open immersion.

Consider the Bialynicki-Birula cell

\[ X(\lambda, z) = \{p \in X : \lim_{t \to 0} \lambda(t)p = z\}. \]

Notice that \(y \in X(\lambda, z)\). By [BL87, Propositions 2.1 and 2.3], \(X(\lambda, z) \cap G.x = B(\lambda).y\) and \(G.x \cap S = T.y'\) for some \(y' \in B(\lambda).y\). Then, the proof of [BL87, Proposition 2.3] shows that \(\Theta\) induces by restriction an isomorphism:

\[ \left(P \cap B(\lambda)\right) \times_{B(\lambda)z} \left((A \cap B(\lambda)) \times T.y'\right) \rightarrow B(\lambda).y. \]

Since \(T\) is contained in \(B(\lambda)z\), this isomorphism implies that

\[ \text{rk}(B(\lambda).y) = \dim(T.y') = \dim S. \tag{2} \]

The lemma follows from Equalities 1 and 2. \qed
3 Reduction to the case when $G$ and $H$ are semi-simple

The goal of this section is to reduce the classification of the spherical pairs $(G, H)$ to those with $G$ semi-simple adjoint and $H$ semi-simple.

**Proposition 3.1** Let $(G, H)$ be a spherical pair of minimal rank.

Then, there exists a parabolic subgroup $P$ of $G$ with a Levi decomposition $P = P^u L$ and a reductive subgroup $K$ of $L$ such that:

(i) $H = P^u K$

(ii) $(L, K)$ is a spherical pair of minimal rank.

**Proof.** We can write $H = H^u K$, where $K$ is a reductive subgroup of $H$. But, by [Humphreys, 30.3], there exists a parabolic subgroup $P = P^u L$ of $G$ such that $H^u \subseteq P^u$ and $K \subseteq L$. We claim that $P$ and $L$ satisfy the proposition.

Let firstly prove that $P^u = H^u$.

Let $T(H)$ be a maximal torus of $K$ (and hence of $H$). The variety $\mathcal{B}$ contains an open subset stable by $P$ (and hence by $H$) isomorphic to $P^u \times \mathcal{B}(L)$ (with obvious notation). By assumption, there exists a point $x$ in $\mathcal{B}$ fixed by $T(H)$ such that $H^u x$ is open in $\mathcal{B}$. But, $x = (u, y)$ belongs to $P^u \times \mathcal{B}(L)$. Since the $H$-orbit of $x$ is open in $P^u \times \mathcal{B}(L)$, so is its intersection with $P^u \times \{y\}$. Hence, the set of the $hkuk^{-1} \in P^u$ such that $h \in H^u$ and $k \in K$ is open and dense in $P^u$. In particular, the $K_y$-orbit $K_y.(uH^u)$ is open and dense in $P^u/H^u$.

Since $x \in \mathcal{B}^{T(H)}$, $uH^u \in (P^u/H^u)^{T(H)}$. But, $K_y$ is a solvable group with $T(H)$ as maximal torus. So, $K_y^u.uH^u$ is one orbit of the unipotent radical $K_y^u$ of $K_y$. In particular, it is closed in the affine variety $P^u/H^u$. But it is also open. We deduce that $K_y$ acts transitively on $P^u/H^u$.

But $K_y^u$ is contained in $K$ and normalizes $H^u$. So, $H^u$ is a fix point of $K_y$ in $P^u/H^u$. We deduce that $P^u/H^u$ has only one point ; that is, that $P^u = H^u$.

On the other hand, $K.y$ is open in $\mathcal{B}(L)$ and $y$ is fixed by the maximal torus $T(H)$ of $K$. We deduce that $(L, K)$ is a spherical pair of minimal rank. □

Since the parabolic subgroups of a given reductive group are very well known, Proposition 3.1 reduces the problem of classification of the spherical pairs $(G, H)$ of minimal rank to the case when $H$ is reductive.

**Proposition 3.2** Let $G$ be a connected reductive group. Set $G_{ad} = G/Z(G)$ and consider the projection $p : G \rightarrow G_{ad}$. Let $H$ be a reductive subgroup of $G$. Then,

(i) The pair $(G, H)$ is spherical of minimal rank if and only if the pair $(G_{ad}, p(H))$ is.

(ii) The pair $(G, H)$ is spherical of minimal rank if and only if the pair $(G, H^u)$ is.

9
If $G/H$ is of minimal rank, the neutral component $p(H)^\circ$ of $p(H)$ is semi-simple.

Proof. Assertions (i) and (ii) are obvious from Assertion (i) of Proposition 2.1.

To prove the last assertion, it is sufficient to prove that the connected center $S$ of $H$ is contained in the center of $G$. There exists $x \in \mathcal{B}$ fixed by $S$ such that $H.x$ is open in $\mathcal{B}$. Since, $H \subset G^S$, $G^S.x$ is open in $\mathcal{B}$. But, $G^S.x$ is an irreducible component of $\mathcal{B}^S$. Therefore, $\mathcal{B}^S = \mathcal{B}$ and $S$ is central in $G$. □

Proposition 3.2 reduces the problem of classification of the spherical pairs $(G, H)$ of minimal rank to the case when $G$ is semi-simple adjoint and $H$ is semi-simple. From now on, we only consider such pairs.

4 Classification of Lie algebras

Let $(G, H)$ be a spherical pair of minimal rank with $G$ semi-simple adjoint and $H$ semi-simple. Let $\mathfrak{g}$ (resp. $\mathfrak{h}$) denote the Lie algebra of $G$ (resp. $H$).

4.1 Root systems of $\mathfrak{g}$ and $\mathfrak{h}$

Let $T(H)$ be a maximal torus of $H$. Let $T \supset T(H)$ be a maximal torus of $G$. Let $\mathcal{X}(T) = \text{Hom}(T, \mathbb{K}^*)$ (resp. $\mathcal{X}(T(H)) = \text{Hom}(T(H), \mathbb{K}^*)$) denote the character group of $T$ (resp. $T(H)$). Let $\phi_\mathfrak{g} \subset \mathcal{X}(T)$ (resp. $\phi_\mathfrak{h} \subset \mathcal{X}(T(H))$) be the set of roots of $\mathfrak{g}$ (resp. $\mathfrak{h}$). Let $\rho : \mathcal{X}(T) \longrightarrow \mathcal{X}(T(H))$ be the restriction map.

In this subsection, we will prove some very constraining relations between $\phi_\mathfrak{g}$, $\phi_\mathfrak{h}$ and $\rho$.

4.1.1

The following stability of the set spherical pairs of minimal rank will be used to localize the study over some fixed roots of $\mathfrak{h}$:

Lemma 4.1 Let $S$ be a subtorus of $H$.
Then, $(G^S, H^S)$ is a spherical pair of minimal rank.

Proof. Let $T(H)$ be a maximal torus of $H$ which contains $S$. Let $x$ be a fixed point of $T(H)$ in $\mathcal{B}$ such that $H.x$ is open in $\mathcal{B}$. Since $V \cap G^S.x$ is open in $G^S.x$, it is irreducible. So, it is an irreducible component of $V^S$. Now, [Ric82] implies that $V \cap G^S.x = H^S.x$. In particular, $H^S.x$ is open in $G^S.x \simeq \mathcal{B}(G^S)$ and $x$ is fixed by the maximal torus $T(H)$ of $H^S$. The lemma follows. □

Lemma 4.2 With the above notation, we have $\rho(\phi_\mathfrak{g}) = \phi_\mathfrak{h}$. 

10
Proof. Let \( \alpha \in \phi_g \). Set \( S = \text{Ker}(\rho(\alpha))^\circ \subset T(H) \). By Lemma 4.1, \( H^S \) is a spherical subgroup of \( G^S \) and \( \text{rk}(G^S/H^S) = \text{rk}(G^S) - \text{rk}(H^S) \). Since the semi-simple rank of \( G^S \) is one, this implies that \( H^{Sg} \) is not a torus. So, \( \rho(\alpha) \) is a root of \( h \).

Moreover, since \( h \subset g \), \( \phi_h \subset \rho(\phi_g) \).

By Lemma 4.2, we can define the map \( \rho_\phi : \phi_g \rightarrow \phi_h \), \( \alpha \mapsto \rho(\alpha) \).

Lemma 4.3 The spherical pairs \((G, H)\) of minimal rank with \( G \) semi-simple adjoint, \( H \) connected and \( h = \mathfrak{sl}_2 \) are:

(i) \((\text{PSL}_2, \text{PSL}_2)\).

(ii) \(\text{PSL}_2 \) diagonally embedded in \(\text{PSL}_2 \times \text{PSL}_2\).

Proof. By Assertion (i) of Proposition 2.1, the dimension of \( B \) is at most 2. We deduce that \( G = \text{PSL}_2 \) or \( \text{PSL}_2 \times \text{PSL}_2 \). The lemma follows easily. \( \Box \)

Lemma 4.4 Let \( \alpha \in \phi_h \).

Then, \( \rho_\phi^{-1}(\alpha) \) contains either one root of \( g \) or two orthogonal roots of \( g \). Moreover, if \( \rho_\phi^{-1}(\alpha) = \{\alpha^o\} \) then \( h_\alpha = g_{\alpha^o} \); and if \( \rho_\phi^{-1}(\alpha) = \{\alpha^-, \alpha^+\} \) with \( \alpha^- \neq \alpha^+ \in \phi_g \) then \( h_\alpha \neq g_{\alpha^+} \).

Proof. Set \( S = \text{ker}(\alpha)^o \). Since \( h^S \simeq \mathfrak{sl}_2 \) and by Lemma 4.1, we can apply Lemma 4.3 to \((G^S/S, H^S/S)\). The lemma follows immediately. \( \Box \)

Lemma 4.4 divides the set of roots of \( h \) in two kinds:

\[ \phi_h^1 := \{ \alpha \in \phi_h : |\rho_\phi^{-1}(\alpha)| = 1 \} \quad \text{and} \quad \phi_h^2 := \{ \alpha \in \phi_h : |\rho_\phi^{-1}(\alpha)| = 2 \} \]

We denote by \( W_H \) the Weyl group \( N_H(T(H))/T(H) \) of \( H \).

Lemma 4.5 The sets \( \phi_h^1 \) and \( \phi_h^2 \) are stable by the action of \( W_H \).

Proof. By Lemma 4.1, \((G^{T(H)}, T(H))\) is a spherical pair of minimal rank. So, \( G^{T(H)} \) is a torus and \( G^{T(H)} = T \). In particular, \( N_H(T(H)) \) is contained in \( N_G(T) \); this inclusion induces an injection of \( W_H = N_H(T(H))/T(H) \) into \( W = N_G(T)/T \). By this injection, we obtain an action of \( W_H \) on \( X(T) \) such that \( \rho \) is \( W_H \)-equivariant. The lemma follows. \( \Box \)

4.1.2 Simple roots

In Section 4.1.1, we just proved that \( \rho \) induces a map from \( \phi_h \) onto \( \phi_h \). In this section, we will prove that \( \rho \) induces a map from the Dynkin diagram of \( g \) onto those of \( h \).

Let us fix a choice \( \phi_h^+ \) of positive roots for \( h \). Set \( \phi_g^+ = \rho_\phi^{-1}(\phi_h^+) \). Let \( \Delta_g \) (resp. \( \Delta_h \)) be the set of simple roots of \( \phi_g \) (resp. \( \phi_h \)).
Lemma 4.6 Let $\alpha$ be a root of $g$. Then, $\alpha \in \Delta_g$ if and only if $\rho_\phi(\alpha) \in \Delta_h$.

Proof. Since $\alpha \in \phi^+_g$ if and only if $\rho(\alpha) \in \phi^+_h$, we may assume that $\alpha \in \phi^+_g$.

Let us assume that $\alpha \notin \Delta_g$. Then, there exists $\beta$ and $\gamma$ in $\phi^+_g$ such that $\alpha = \beta + \gamma$. By applying $\rho$, we see that $\rho(\alpha)$ does not lie in $\Delta_h$.

Let us assume that $\alpha \in \Delta_g$. By absurd, we assume that there exists $\beta$ and $\gamma$ in $\phi^+_g$ such that $\rho(\alpha) = \beta + \gamma$. Three cases occurs:

Case 1: $\beta$ and $\gamma$ belong to $\phi^+_h$.

Let $\beta^o$ and $\gamma^o$ be in $\phi_g$ such that $\rho(\beta^o) = \beta$ and $\rho(\gamma^o) = \gamma$. By Lemma 4.3, $g_{\beta^o} = h_\beta$ and $g_{\gamma^o} = h_\gamma$. So, we have:

$$[g_{\beta^o}, g_{\gamma^o}] = [h_\beta, h_\gamma] = h_{\rho^o(\alpha)}.$$  

In particular this bracket is non zero and $\beta^o + \gamma^o$ is a root of $g$. Moreover, $g_{\beta^o + \gamma^o} = h_{\rho^o(\alpha)}$. So, Lemma 4.3 shows that $\rho(\alpha) \in \phi^+_h$. But $\alpha$ and $\beta^o + \gamma^o$ belong to $\rho^o(\rho(\alpha))$. So, $\alpha = \beta^o + \gamma^o$; and this root is not simple.

Case 2: $\beta \in \phi^+_h$ and $\gamma \in \phi^+_g$.

Let $\beta^o$ as above. We can write $\rho^{-1}(\gamma) = \{\gamma^+, \gamma^-, \gamma^0\}$. We have:

$$g_{\beta^o + \gamma^+} + g_{\beta^o + \gamma^-} \supset [g_{\beta^o}, g_{\gamma^+} + g_{\gamma^-}] \supset [g_{\beta^o}, h_{\gamma}] = [h_\beta, h_\gamma] = h_{\beta + \gamma} = h_{\rho(\alpha)}.$$  

Moreover, since $h_\gamma$ is different from $g_{\gamma^+}$ and $g_{\gamma^-}$, $h_{\rho(\alpha)}$ is different from $g_{\beta^o + \gamma^+}$ and $g_{\beta^o + \gamma^-}$. In particular, $\beta^o + \gamma^+$ and $\beta^o + \gamma^-$ are roots of $g$; and $\rho^{-1}(\rho(\alpha)) = \{\beta^o + \gamma^+, \beta^o + \gamma^-, \beta^o + \gamma^0\}$. So, $\alpha = \beta^o + \gamma^+$ or $\beta^o + \gamma^-$; and this root is not simple.

Case 3: $\beta$ and $\gamma$ belong to $\phi^+_h$.

With obvious notation, we have:

$$g_{\beta^o + \gamma^+} + g_{\beta^o + \gamma^-} + g_{\beta^o - \gamma^+} + g_{\beta^o - \gamma^-} \supset [h_\beta, h_\gamma] = h_{\beta + \gamma}.$$  

If $h_{\beta + \gamma}$ equals one of the four spaces $g_{\beta^o \pm \gamma^o}$, Lemma 4.4 shows that $\alpha$ equals $\beta^o \pm \gamma^o$ and is not a simple root. Else, two of the four spaces $g_{\beta^o \pm \gamma^o}$ are not zero and $\alpha$ equals one of the two corresponding roots; in particular $\alpha$ is not simple. \hfill $\square$

Consider the map

$$\rho_\Delta : \Delta_g \longrightarrow \Delta_h$$  

$$\alpha \longmapsto \rho_\phi(\alpha).$$

Set $\Delta^2_h = \Delta_h \cap \phi^2_h$ and $\Delta^1_h = \Delta_h \cap \phi^1_h$.

On the Dynkin diagram of $\mathfrak{h}$, we color in black the simple roots in $\Delta^2_h$. The so obtained diagram is called the colored Dynkin diagram of $\mathfrak{h}$ and is denoted by $\overline{D}_\mathfrak{h}$. From now on, when we draw the Dynkin diagram $D_\mathfrak{g}$ of $\mathfrak{g}$, two simple roots $\alpha$ and $\beta$ are placed on the same vertical line if and only if $\rho_\Delta(\alpha) = \rho_\Delta(\beta)$; in such a way, $\rho_\Delta$ identifies with the vertical projection. Note that by Lemma 4.4, $\alpha$ and $\beta$ are orthogonal. For $(\text{PSL}_4, \text{PSp}_4)$, we obtain the following picture:
By exchanging the simple roots in a fiber of $\rho_\Delta$, we define an involution $\sigma_h$ on the set of vertices of the Dynkin diagram of $\mathfrak{g}$.

4.2 A result of unicity

**Proposition 4.1** For a fixed pair $(\mathcal{D}_g, \sigma_h)$ there exists at most one (up to conjugacy by an element of $G$) spherical pair $(G, H)$ where $G$ is adjoint and $H$ connected.

**Proof.** Obviously, $G$ is determined by $\mathcal{D}_g$. Let us fix a Borel subgroup $B$ of $G$ and a maximal torus $T$ of $B$. Let $\Delta_g$ denote the set of simple roots of $G$. For any $\alpha \in \Delta_g$, we fix a $\mathfrak{sl}_2$-triple $(X_\alpha, Y_\alpha, H_\alpha)$. Consider

$$\Theta : T \longrightarrow (\mathbb{K}^*)^{\Delta^2_g} \quad t \longmapsto (\beta(t)\alpha(t^{-1}))_{\alpha \neq \beta \in \Delta_g} \quad \rho_\Delta(\alpha) = \rho_\Delta(\beta).$$

The neutral component $S$ of the kernel of $\Theta$ is a subtorus of $T$ of dimension $|\Delta_g| - |\Delta^2_g| = |\Delta_h|$. Moreover, $\Theta$ is surjective.

Let $H$ be a semi-simple subgroup of $G$ such that $(G, H)$ is a spherical pair of minimal rank with $(\mathcal{D}_g, \mathcal{D}_h, \rho_\Delta)$ as associated triple. Let $T(H)$ be a maximal torus of $G$. Up to conjugacy, we may assume that $T(H)$ is contained in $T$. But, $T(H)$ is contained in $S$; by an argument of dimension, we conclude that $T(H) = S$.

For all $\alpha \in \Delta^1_g$, we have $\mathfrak{g}_\alpha = \mathfrak{h}_{\rho(\alpha)}$. Moreover, we claim that up to conjugacy, we may assume that for all $\alpha \neq \beta \in \Delta_g$ such that $\rho_\Delta(\alpha) = \rho_\Delta(\beta)$ we have $\mathfrak{h}_{\rho(\alpha)} = \mathbb{K}(X_\alpha + X_\beta)$.

We write $\Delta^2_g = \{\alpha_1, \ldots, \alpha_k\}$ and $\Delta^2_h = \{\alpha_1^+, \ldots, \alpha_k^+\} \cup \{\alpha_1^-, \ldots, \alpha_k^-\}$ such that for all $i = 1, \ldots, k$, $\rho(\alpha_i^+) = \alpha_i$. By Lemma 4.4, there exist $(x_1, \ldots, x_k) \in \mathbb{K}^k$ such that for all $i = 1, \ldots, k$, $\mathfrak{h}_{\alpha_i} = \mathbb{K}(X_{\alpha_i^-} + x_iX_{\alpha_i^+})$. Since $\Theta$ is surjective, there exists $t \in T$ such that $\Theta(t) = (x_1, \ldots, x_k)$. By conjugating $H$ by $t$, we obtain the claim.

Let $i \in \{1, \ldots, k\}$. There exists $y \in \mathbb{K}^*$ such that $\mathfrak{h}_{-\alpha_i} = \mathbb{K}(Y_{\alpha_i^-} + yY_{\alpha_i^+})$. Since $\alpha_i^-$ and $\alpha_i^+$ are orthogonal, $\xi := [X_{\alpha_i^-} + X_{\alpha_i^+}, Y_{\alpha_i^-} + yY_{\alpha_i^+}] = H_{\alpha_i^-} + yH_{\alpha_i^+}$. But, $\xi$ belongs to the Lie algebra of $T(H)$, that is to $S$, so $(\alpha_i^- - \alpha_i^+)(\xi) = 0$. We conclude that $y = 1$.

Finally, since $\mathfrak{h}$ is generated as Lie algebra by the $\mathfrak{h}_{\pm \alpha}$ for $\alpha \in \Delta_h$; $\mathfrak{h}$ is generated by:

$$\{X_\alpha\}_{\alpha \in \Delta^1_h} \cup \{Y_\alpha\}_{\alpha \in \Delta^2_h} \cup \{X_{\alpha_i^-} + X_{\alpha_i^+}\}_{\alpha \in \Delta^2_h} \cup \{Y_{\alpha_i^-} + Y_{\alpha_i^+}\}_{\alpha \in \Delta^2_h}.$$

In particular, $\mathfrak{h}$ only depends on the triple $(\mathcal{D}_g, \sigma_h)$. □
4.2.1 The case when $\text{rk}(H) = 2$

Lemma 4.3 considers the case when $\text{rk}(H) = 1$. We now consider the case when $\text{rk}(H) = 2$:

**Lemma 4.7** We assume that $\text{rk}(H) = 2$. Then, the possibilities for $(D_g, \sigma_h)$ are:

(i) $(D_h, \text{Identity})$ obtained with $G = H$.

(ii) $(D_h \cup D_h, \text{Exchange})$ obtained with $H$ embedded diagonally in $H \times H$.

(iii) $D_g = A_3$ and $\sigma_h$ fixes the central vertex and exchanges the two others; obtained with $H = \text{PSp}_4 \subset G = \text{PSL}_4$:

\[
\begin{array}{c}
\circ \\
\circ \\
\end{array}
\]

(iv) $D_g = B_3$ and $\sigma_h$ fixes the central vertex and exchanges the two others; obtained with $G_2 \subset \text{SO}_7$:

\[
\begin{array}{c}
\circ \\
\circ \\
\end{array}
\]

**Proof.** If $\phi_h^2$ is empty, the dimensions of $g$ and $h$ are equal and hence $g = h$. From now on, we assume that $\phi_h^2$ is not empty. Since $\phi_h^2$ is stable by the action of the Weyl group $W_H$ of $H$, $\Delta_h^2$ is non empty.

By invariance by $W_H$ the possibilities for colored Dynkin diagrams of $h$ are:

\[
\begin{array}{cccccccc}
\circ & \circ & \circ & \circ & \circ & \circ & \circ & \circ \\
\circ & \circ & \circ & \circ & \circ & \circ & \circ & \circ \\
\circ & \circ & \circ & \circ & \circ & \circ & \circ & \circ \\
\circ & \circ & \circ & \circ & \circ & \circ & \circ & \circ \\
\end{array}
\]

In each case, using the action of $W_H$, one can determine $\phi_h^1$ and $\phi_h^2$ and thus, compute the cardinality $|\phi_g|$ of $\phi_g$ which equals $|\phi_h^1| + 2|\phi_h^2|$. Moreover, by Lemma 4.3 the two simple roots of $g$ which map on a simple root of $\phi_h^2$ are orthogonal. These constraints imply a small number of possibilities for $(D_g, D_h, \rho_D)$. In the following tabular, we list these possibilities omitting those corresponding to $h \subset h \times h$ and $\mathfrak{sl}_2 \times \mathfrak{sl}_2 \rightarrow \mathfrak{sl}_2 \times \mathfrak{sl}_2 \times \mathfrak{sl}_2, (\xi, \eta) \mapsto (\xi, \xi, \eta)$.
| Case | $\mathfrak{h}$ | Colored Dynkin diagram of $\mathfrak{h}$ | $(|\phi^1_\mathfrak{h}|, |\phi^2_\mathfrak{h}|)$ | $|\phi_\mathfrak{g}|$ | Dynkin diagram of $\mathfrak{g}$  |
|------|----------------|---------------------------------------------|---------------------------------|----------------|---------------------------------|
| 1    | $\mathfrak{sl}_3$ | ![Dynkin diagram of $\mathfrak{sl}_3$](#) | $(0,6)$ | 12 | $\mathfrak{sp}_4 \times \mathfrak{sl}_2 \times \mathfrak{sl}_2$ |
| 2    | $\mathfrak{sp}_4$ | ![Dynkin diagram of $\mathfrak{sp}_4$](#) | $(0,8)$ | 16 | $\mathfrak{sp}_4 \times \mathfrak{sp}_4$ |
| 3    | $\mathfrak{sp}_4$ | ![Dynkin diagram of $\mathfrak{sp}_4$](#) | $(4,4)$ | 12 | $\mathfrak{sl}_4$ |
| 4    | $\mathfrak{sp}_4$ | ![Dynkin diagram of $\mathfrak{sp}_4$](#) | $(4,4)$ | 12 | $\mathfrak{sl}_4$ |
| 5    | $G_2$ | ![Dynkin diagram of $G_2$](#) | $(0,12)$ | 24 | $\mathfrak{sp}_8$ |
| 6    | $G_2$ | ![Dynkin diagram of $G_2$](#) | $(6,6)$ | 18 | $\mathfrak{so}_7$ |
| 7    | $G_2$ | ![Dynkin diagram of $G_2$](#) | $(6,6)$ | 18 | $\mathfrak{so}_7$ |

There is no nontrivial action of the group $\text{PSL}_3$ on $\mathbb{P}^1$. But in Case 1, $\mathbb{P}^1$ is a factor of $\mathcal{B}$; and $H$ cannot have a dense orbit in $\mathcal{B}$. In Case 2, the projections of $\mathfrak{h}$ on each factor of $\mathfrak{g}$ are isomorphisms: Case 2 also cannot occur.

Consider Case 3. Let $\alpha$ (resp. $\beta$) denote the short (resp. long) simple root of $\mathfrak{h}$. Set $\alpha^o = \rho_\Delta^{-1}(\alpha)$ and $(\alpha + \beta)^o = \rho_\Delta^{-1}(\alpha + \beta)$. By Lemma 4.5, $\alpha + \beta \in \phi^1_\mathfrak{h}$. So,

$$\mathfrak{h}_{2\alpha+\beta} = [\mathfrak{h}_\alpha, \mathfrak{h}_{\alpha+\beta}] = [\mathfrak{g}_{\alpha^o}, \mathfrak{g}_{(\alpha+\beta)^o}] = \mathfrak{g}_{\alpha^o+(\alpha+\beta)^o}.$$
Now, Lemma 4.4 shows that $2\alpha + \beta \in \phi^1_\alpha$. With Lemma 4.5, this contradicts $\beta \in \phi^2_\beta$.

By elimination, the inclusion of $\text{PSp}_4$ in $\text{PSL}_4$ corresponds to Case 4.

Consider Case 5. We label the simple roots of $g$ and $h$ as follows:

![Dynkin diagram of g]

$$
\begin{align*}
\alpha_3 & \quad \alpha_4 \\
\alpha_1 & \quad \alpha_2 \\
\alpha & \quad \beta
\end{align*}
$$

We have $\rho(\alpha_3 + \alpha_4) = \rho(\alpha_2 + \alpha_1) = \alpha + \beta$; but $\alpha_3 + \alpha_4$, $\alpha_2 + \alpha_1$ and $\alpha_2 + \alpha_3$ are three distinct roots of $g$. This contradicts Lemma 4.4.

Consider Case 6. Let $\alpha$ (resp. $\beta$) denote the short (resp. long) simple root of $h$. By Lemma 4.5, $\beta + 2\alpha$ belongs to $\phi^1_h$. By the argument used in Case 3 before, one easily checks that $\beta + 3\alpha = (\beta + 2\alpha) + \alpha$ belongs to $\phi^1_h$. This contradicts Lemma 4.5, since $\beta + 3\alpha$ is a long root.

Case 7 corresponds to the inclusion of $G_2$ in $\text{SO}_7$. □

We may now assume that $H$ is simple. Indeed, we have:

**Proposition 4.2** Let $(G, H)$ be a spherical pair of minimal rank with $G$ semi-simple adjoint and $H$ connected. If $H$ is not simple then there exist two spherical pairs $(G_1, H_1)$ and $(G_2, H_2)$ of minimal rank such that $G = G_1 \times G_2$ and $H = H_1 \times H_2$.

**Proof.** By assumption, $D_h$ is the disjoint union of two Dynkin diagrams $D_1$ and $D_2$. By Lemmas 4.7 and 4.1, for all $\alpha, \beta \in \Delta_g$ such that $\rho(\alpha)$ and $\rho(\beta)$ are orthogonal, $\alpha$ and $\beta$ are orthogonal. We deduce that $D_g$ is the disjoint union of $\rho^{-1}_\Delta(D_1)$ and $\rho^{-1}_\Delta(D_2)$. The proposition follows. □

By Proposition 4.2, to classify all the spherical pairs $(G, H)$ of minimal rank with $G$ simple-simple adjoint and $H$ semi-simple, we may assume that $H$ is simple. The Theorem A stated in the introduction lists all such spherical pairs. We can now prove this classification.

**Proof.**[of Theorem A] By Proposition 4.1, it is sufficient to classify the possible triples $(D_g, D_h, \rho_\Delta)$. By Lemma 4.7, we may assume that $\text{rk}(H) \geq 3$. Moreover, we may assume that $\Delta^2_h$ is non-empty and different from $\Delta_h$. Let $\alpha \in \Delta^2_h$ and $\beta \in \Delta^1_h$. By Lemma 4.7, either $\alpha$ and $\beta$ are orthogonal or $\alpha$ is the short root joined to the long root $\beta$ by a double edge.

One easily deduces that the colored Dynkin diagram of $h$ is one of the following:

![Dynkin diagram of h]
One easily deduces from Lemmas 4.1 and 4.7 than in the three preceding case the Dynkin diagram $D_6$ is respectively:

The theorem follows.
