Kyoji Saito **

Abstract. We introduce two spaces \( \Omega(\Gamma, G) \) and \( \Omega(\mathcal{P}_{\Gamma, G}) \) of pre-partition functions and of opposite series, respectively, which are associated with a Cayley graph \((\Gamma, G)\) of a cancellative monoid \(\Gamma\) with a finite generating system \(G\) and with its growth function \(\mathcal{P}_{\Gamma, G}(t)\). Under mild assumptions on \((\Gamma, G)\), we introduce a fibration \(\pi_\Omega: \Omega(\Gamma, G) \to \Omega(\mathcal{P}_{\Gamma, G})\) equivariant with a \(\mathbb{Z}_{\geq 0}\)-action, which is transitive if it is of finite order. Then, the sum of pre-partition functions in a fiber is a linear combination of residues of the proportion of two growth functions \(\mathcal{P}_{\Gamma, G}(t)\) and \(\mathcal{P}_{\Gamma, GM}(t)\) attached to \((\Gamma, G)\) at the places of poles on the circle of the convergent radius.

* The present paper is a complete version of the announcement [Sa2] based on the preprint RIMS-726. We rewrote the introduction, left out the filtration by \((p, q)\), divided section §10 into §10 and 11, and updated the references. The §11, 12 are newly written, where, applying the results in §2-10 to Cayley graphs \((\Gamma, G)\) of a cancellative monoid, we introduce a fibration \(\Omega(\Gamma, G) \to \Omega(\mathcal{P}_{\Gamma, G})\) of our interest. In Winter semester 05-06 at RIMS, the author held a series of seminars on the present paper. He thanks to its participants Yohei Komori, Michihiko Fujii, Yasushi Yamashita, Masahiko Yoshinaga, Takefumi Kondo, and Makoto Fuchiwaki. Particular thanks go to Yohei Komori, without whose encouragement, this paper would not have appeared. The author is also grateful to Brian Forbes and Ken Shackleton for the careful reading of the manuscript.

§1. Introduction

Replacing the square lattice $\mathbb{Z}^2$ in the classical Ising model ([Cu][I][O][Ba]) by a Cayley graph $(\Gamma, G)$ of a cancellative monoid $\Gamma$ with a finite generating system $G$, we introduce the space $\Omega(\Gamma, G)$ of pre-partition functions. Here, the word pre-partition function is used only in the present introduction for a reason we explain now. Namely, for any finite region $T$ of the Cayley graph, we define the free energy $\frac{M(T)}{\#(T)}$ by the logarithm of the sum of configurations in $T$ ((5.1.5) and (6.1.1)), and then consider accumulating points set $\Omega(\Gamma, G)$ (in a suitable topological setting) of the sequence $\{\frac{M(\Gamma_n)}{\#(\Gamma_n)}\}_{n \in \mathbb{Z}_+}$ of free energies of balls $\Gamma_n$ of radius $n$ in $\Gamma, G$ (§11.1 Definition). In the case of $\Gamma = \mathbb{Z}^2$, $\Omega(\Gamma, G)$ consists of a single element. By inputting the data of Boltzmann weights to it, we get the partition function: an elliptic function dependent on the parameters involved in the Boltzmann weights. This fact, inspired the author to use the pre-partition functions to construct functions on the moduli of $\Gamma$ ([Sa1,3]).

In our new setting, the space $\Omega(\Gamma, G)$ is no longer a single element set but is a compact Hausdorff space. Under mild assumptions on $(\Gamma, G)$, we construct a fibration $\pi_\Omega : \Omega(\Gamma, G) \rightarrow \Omega(P_\Gamma, G)$ (11.2.12), where $\Omega(P_\Gamma, G)$ is another newly introduced compact space, consisting of opposite sequences of the growth function $P_\Gamma(t)$ (11.2.3). The fibration is equivariant with an action $\tau_\Omega$. If the action
Kyoji Saito

is of finite order, then it is transitive and the sum of the partition functions in
a fiber of $\pi_\Omega$ is given by a linear combination of the proportions of residues of
the two series $P_{\Gamma,G}\mathcal{M}(t) := \sum_{n=0}^{\infty} \mathcal{M}(\Gamma_n) t^n$ and $P_{\Gamma,G}(t) := \sum_{n=0}^{\infty} #(\Gamma_n) t^n$ at
their poles on the circle $|t| = r_{\Gamma,G}$ of convergent radius $r_{\Gamma,G}$. We publish these
results in the present paper, eventhough our original attempt is not achieved.

The paper is divided into two parts. In the first part $\S 2-10$, we develop a
general frame work on a topological Hopf algebra $R[\text{Conf}]$ called the
configuration algebra, where necessary concepts such as the configuration sums, the
free energies (called equally dividing points) etc. are introduced. The algebra
is equipped with two (one adic and the other classical) topologies in order to
discuss carefully limit process in it. Then, inside its subspace $L_{R,\infty}$ of Lie-like
elements at infinity, the set $\Omega_\infty := \log(\text{EDP})_\infty$ of all accumulation points of
all free energies is introduced. In the second half, $\S 11-12$, we consider a Cayley
graph $(\Gamma,G)$ of a monoid. Then, the set of pre-partition functions $\Omega(\Gamma,G)$ is
defined as the subset of $\Omega_\infty$ of all accumulating points of the sequence of free
energies of the balls $\Gamma_n$ of radius $n \in \mathbb{Z}_{\geq 0}$ in $(\Gamma,G)$. We also introduce another
limit set $\Omega(P_{\Gamma,G}) \subset R[s]$, called the space of opposite sequences, depending only
on the Poincare series $P_{\Gamma,G}(t)$ of $(\Gamma,G)$ (see (11.2.1-4) and (11.2.6)). The space $\Omega(P_{\Gamma,G})$ is the key to relate the space $\Omega(\Gamma,G)$ with the singularities of the
Poincare series $P_{\Gamma,G}(t)$ on the circle $|t| = r_{\Gamma,G}$ of convergence ($\S 11$ Theorems
1-5). Then, comparing the two limit spaces $\Omega(\Gamma,G)$ and $\Omega(P_{\Gamma,G})$, we arrive at
the goal: a residual presentation of pre-partition functions ($\S 11$ Theorem 6.)

Let us explain the contents of the present paper in more detail.

The isomorphism class of a colored oriented finite graph is called a configuration. The set of all configurations with fixed bounds of valency and colors,
denoted by $\text{Conf}$, has an additive monoid structure generated by $\text{Conf}_0$, isomor-
phism classes of connected graphs (by taking the disjoint union as the product)
and a partial ordering structure ($\S 2.3$). In $\S 2.4$, we introduce the basic invariant
$(s_1, \ldots, s_m) \in \mathbb{Z}_{\geq 0}$ for $s_1, \ldots, s_m$ and $S \in \text{Conf}$, called a covering coefficient.
We denote by $A[\text{Conf}]$ the completion of the semigroup ring $A \cdot \text{Conf}$ with re-
spect to the grading $\deg(S) : = \#(S)$, called the configuration algebra ($\S 3$), where
$A$ is the ring of coefficients. The algebra $A[\text{Conf}]$ carries a topological Hopf
algebra structure by taking the covering coefficients as structure constants ($\S 4$).

For a configuration $S \in \text{Conf}$, let $A(S) \in A \cdot \text{Conf}$ be the sum of all its sub-
graphs, the configuration sum. We put $\mathcal{M}(S) := \log(A(S))$, then $\{\mathcal{M}(S)\}_{S \in \text{Conf}_0}$
forms a basis of the Lie-like space of the noncomplete bi-algebra $A \cdot \text{Conf}$ ($\S 5$
and 6). However, this is not a topological basis of the Lie-like space $L_A$ of
the algebra $A[\text{Conf}]$. Therefore, we introduce a topological basis, denoted by
$\{\varphi(S)\}_{S \in \text{Conf}_0}$, of $L_A$. The coefficients of the transformation matrix between
$\{M(S)\}_{S \in \text{Conf}_0}$ and $\{\varphi(S)\}_{S \in \text{Conf}_0}$ are described by \textit{kabi-coefficients}, introduced in \S7. The base-change induces a linear map, called the \textit{kabi-map}, from $L_h$ to a formal module spanned by $\{M(S)\}_{S \in \text{Conf}_0}$. The kernel of the \textit{kabi-map} is denoted by $L_{h,\infty}$ and is called the \textit{Lie-like space at infinity} (\S8).

The group-like elements $\mathcal{G}_{Z,\text{finite}}$ of the configuration algebra $Z[\text{Conf}]$ is isomorphic to the fractional group of the monoid $\text{Conf}$ by the correspondence $A$ isomorphic to the fractional group of the monoid $\text{Conf}$ by the correspondence $A$.

In order to study the multi-accumulating cases, we introduce in \S11 another compact accumulating set $\Omega(P_{G,G})$: the \textit{space of opposite series of the growth series} $P_{G,G}(t) := \sum_{n=0}^{\infty} #(\Gamma_n) t^n$. Under mild Assumptions 1 in \S11.1 and 2 in \S11.2 on $(\Gamma, G)$, we show that a natural proper surjective map $\pi_\Omega : \Omega(\Gamma, G) \rightarrow \Omega(P_{G,G})$ equivariant with an action of $Z_{\geq 0}$ exists (see 11.2 Theorems 1, 2, 3 and 4., where i) $\pi_\Omega$ is a forgetful map which remembers only the portion $\lim_{n \rightarrow \infty} A(\Gamma_{n-k}, \Gamma_n) / \#(\Gamma_n)$ of the limit elements (here $A(\Gamma_{n-k}, \Gamma_n) := \#$ of subgraphs of $\Gamma_n$ isomorphic to $\Gamma_{n-k}$) and ii) the $Z_{\geq 0}$-action on $\Omega(\Gamma, G)$ is generated by the map $\tilde{\tau}_\Omega$: the limit element $\lim_{m \rightarrow \infty} A(\Gamma_{m-n}, \Gamma_m) / \#(\Gamma_m)$ is the limit element $\lim_{m \rightarrow \infty} A(\Gamma_{m-n}, \Gamma_m) / \#(\Gamma_m)$. This $\tilde{\tau}_\Omega$-action, up to an initial constant factor, has an interpretation by the fattening action on $\text{Conf}$: $S \mapsto S \Gamma_1$ (here, $S \Gamma_1$ is the equivalence class of $S \cdot \Gamma_1$ for a representative $S$ of $S$) in the level of $\Omega(\Gamma, G)$, and interpretation by the degree shift action $t^n \mapsto t^{n+1}$ in the level of $\Omega(P_{G,G})$.

Subsections 11.3 and 11.4 are devoted to the study of the space of opposite sequences $\Omega(P)$ for a power series $P(t)$ (11.2.1) in general with a constraint on the growth of coefficients. The main concern is to clarify a certain duality between the set $\Omega(P)$ and the set of singularities of $P(t)$ on the boundary of $\Omega(P)$. 

1 The logarithm $\log(A(S)^{1/#S}) = M(S)^{1/#S}$, which we call the logarithmic equal dividing point, is called the (Helmholz) free energy in statistical mechanics (\cite{Gr1, O1}).
the disc of radius \( r \) of convergence. It asks intricate analysis, and, in the present paper, we have clarified only when \( \Omega(P) \) is a finite set. Actually, if \( \Omega(P) \) is finite, then the \( \mathbb{Z}_{\geq 0} \)-action becomes a cyclic \( \mathbb{Z}/h\mathbb{Z} \) and simple-transitive action.

We explicitly determine \( \Omega(P) \) as a set of rational functions in the opposite variable \( s \) of \( t \) (i.e. \( st = 1 \)). In particular, their common denominator \( \Delta_{P}^{op}(s) \), which is a factor of \( 1 - (rs)^{h} \), has the degree equals to the rank of the space \( \mathbb{R}\Omega(P) \) spanned by \( \Omega(P) \). If, further, \( P(t) \) is meromorphic in a neighborhood of the convergent disc, then the top part \( \Delta_{P}^{top}(t) \) of the denominator of \( P(t) \) on the convergent circle of radius \( r \) (see (11.4.1)) and the opposite denominator \( \Delta_{P}^{op}(s) \) are related by the opposite transformation \( st = 1 \) (11.4 Theorem 5).

If \( \Omega(\Gamma, G) \) is finite, then again the \( \mathbb{Z}_{\geq 0} \)-action on \( \Omega(\Gamma, G) \) becomes cyclic \( \mathbb{Z}/\bar{h}\Gamma,G\mathbb{Z} \) and simple-transitive action for some \( \bar{h}\Gamma,G \in \mathbb{Z}_{\geq 0} \) such that \( h\Gamma,G|\bar{h}\Gamma,G \) for the period \( h\Gamma,G \) of the \( \mathbb{Z}_{\geq 0} \)-action on \( \Omega(P) \). Therefore, the map \( \pi_{\Omega} \) is equivalent to the Galois covering map \( \mathbb{Z}/\bar{h}\Gamma,G\mathbb{Z} \rightarrow \mathbb{Z}/h\Gamma,G\mathbb{Z} \). Let us call the kernel of the homomorphism the inertia group and the sum of elements in \( \Omega(\Gamma, G) \) of an orbit of the inertia group a trace element. As the goal of the present paper, we express the trace elements as linear combinations of the proportions \( \frac{P_{\Gamma,G,M}(t)}{P_{\Gamma,G}(t)} \) of the residues of meromorphic functions \( P_{\Gamma,G,M}(t) := \sum_{n=0}^{\infty} M(\Gamma_{n}) t^{n} \) and \( P_{\Gamma,G}(t) \) at the places \( x \) in the root of \( \Delta_{P}^{top}(t) = 0 \). (11.5 Theorem 6). In the proof, we essentially uses the duality theory in 11.4.

Finally in §12, we give a few concluding remarks. Since we are only at the starting of the study of the limit space \( \Omega(\Gamma, G) \), the questions are scattered in various directions of general nature or of specific nature.

As an immediate generalization of our goal Theorem 6 for the cases when \( \Omega(\Gamma, G) \) is not finite, in Problem 1.1, we ask measure theoretic approach for the duality between \( \Omega(P) \) and \( \text{Sing}(P) \), and give a conjectural formula.

Another important generalization of Theorem 6 is the globalization in the following sense: in many important examples, the growth function \( P_{\Gamma,G}(t) \) analytically extends to a meromorphic function in a covering regions of \( \mathbb{C} \) (and same for \( P_{\Gamma,G,M}(t) \)). Let \( x \) be a pole of order \( d \) of such a meromorphic function, then \( \left( \frac{d^{i}}{dt^{i}} \frac{P_{\Gamma,G,M}(t)}{P_{\Gamma,G}(t)} \right) \bigg|_{t=x} \) for \( 0 \leq i < d \) (which we call a residue of depth \( i \) at \( x \)) belongs to \( L_{C,\infty} \) (even though it is no longer a limit element). Theorem 6 treats only the extremal case \( |x| = r \) and \( i = 0 \). Therefore, we ask to study all residues at all possible poles together with a possible action of a Galois group, in particular, to clarify the meaning of the (higher) residues at \( x = 1 \).

We conjecture that hyperbolic groups and some groups of geometric significance (surface groups, mapping class groups and Artin groups for suitable choices of generators) are finite accumulating, i.e. \( \#(\Omega(\Gamma, G)) < \infty \).
§2. Colored graphs and covering coefficients

An isomorphism class of finite graphs with a fixed color-set and a bounded number of edges (valency) at each vertex is called a configuration. The set of all configurations carries the structure of an abelian monoid with a partial ordering. The goal of the present section is to introduce a numerical invariant, called the covering coefficient, and to show some of its basic properties.

2.1 Colored Graphs.

We first give a definition of colored graph which is used in the present paper.

Definition. 1. A pair \((\Gamma, B)\) is called a graph, if \(\Gamma\) is a set and \(B\) is a subset of \(\Gamma \times \Gamma \setminus \Delta\) with \(\sigma(B) = B\), where \(\sigma\) is the involution \(\sigma(\alpha, \beta) := (\beta, \alpha)\) and \(\Delta\) is the diagonal subset. An element of \(\Gamma\) is called a vertex and a \(\sigma\)-orbit in \(B\) is called an edge. A graph is called finite if \(\#\Gamma < \infty\). We sometimes denote a graph by \(\Gamma\) and the set of its vertices by \(|\Gamma|\).

2. Two graphs are isomorphic if there is a bijection of vertices inducing a bijection of edges. Any subset \(S\) of \(|\Gamma|\) carries a graph structure by taking \(B \cap (S \times S)\) as the set of edges for \(S\). The set \(S\) equipped with this graph structure is called a subgraph (or a full subgraph) of \(\Gamma\) and is denoted by the same \(S\). In the present paper, the word “subgraph” shall be used only in this sense, and the notation \(S \subset \Gamma\) shall mean also that \(S\) is a subgraph of \(\Gamma\) associated to the subset. Hence, we have the bijection: \(\{\text{subgraphs of } \Gamma\} \cong \{\text{subsets of } |\Gamma|\}\).

3. A pair \((G, \sigma_G)\) of a set \(G\) and an involution \(\sigma_G\) on \(G\) (i.e. a map \(\sigma_G : G \to G\) with \(\sigma_G^2 = \text{id}_G\)) is called a color set. For a graph \((\Gamma, B)\), a map \(c : B \to G\) is called a \((G, \sigma_G)\)-coloring, or \(G\)-coloring, if \(c\) is equivariant with respect to involutions: \(c \circ \sigma = \sigma_G \circ c\). The pair consisting of a graph and a \(G\)-coloring is called a \(G\)-colored graph. Two \(G\)-colored graphs are called \(G\)-isomorphic if there is an isomorphism of the graphs compatible with the colorings. Subgraphs of a \(G\)-colored graph are naturally \(G\)-colored.

If all points of \(G\) are fixed by \(\sigma_G\), then the graph is called un-oriented. If \(G\) consists of one orbit of \(\sigma_G\), then the graph is called un-colored.

The isomorphism class of a \(G\)-colored graph \(S\) is denoted by \([S]\). Sometimes we will write \(S\) instead of \([S]\) (for instance, we put \(\#[S] := \#S\), and call \([S]\) connected if \(S\) is topologically connected as a simplicial complex).

Example. (Colored Cayley graph of a monoid with cancellation conditions). Let \(\Gamma\) be a monoid satisfying the left and right cancellation conditions: if \(axb = ayb\) in \(\Gamma\) for \(a, b, x, y \in \Gamma\) then \(x = y\) in \(\Gamma\). In the other words, for any two
elements $a, b \in \Gamma$, if there exists $g \in \Gamma$ such that $a = bg$ (resp. $a = gb$) then $g$ is uniquely determined from $a$ and $b$, which we shall denote by $b^{-1}a$ (resp. $ab^{-1}$).

Let $G$ be a finite generating system of $\Gamma$ with $e \notin G$. Then, we equip $\Gamma$ with a graph structure by taking $B := \{(\alpha, \beta) \in \Gamma \times \Gamma : \alpha^{-1}\beta \text{ or } \beta^{-1}\alpha \in G\}$ as the set of edges. Due to the left cancellation condition, it becomes a colored graph by taking $G \cup G^{-1}$ as the color set and by putting $c(\alpha, \beta) = \alpha^{-1}\beta$ for $(\alpha, \beta) \in B$, where $G^{-1}$ is a formally defined set consisting of elements of symbols $\alpha^{-1}$ for $\alpha \in G$ and identifying $\alpha^{-1}$ with $\beta \in G$ if $\alpha\beta = e$ in $\Gamma$ (such $\beta$ may not always exists). Due to the right cancellation condition, for any vertex $x$ and any $\alpha \in G$, vertices connected with $x$ by the edges of color $\alpha$ (i.e. $y \in \Gamma$ s.t. $y\alpha = x$) is unique.

Let us call the graph, denoted by $(\Gamma, G)$ or $\Gamma$ for simplicity, the colored Cayley graph of the monoid $\Gamma$ with respect to the generating system $G$. The left action of $g \in \Gamma$ on $\Gamma$ is a color preserving graph embedding map from $(\Gamma, G)$ to itself.

If $G = G^{-1}$, then $\Gamma$ is a group and the above definition coincides with the usual definition of a Cayley graph of a group.

### 2.2 Configuration.

For the remainder of the paper, we fix a finite color set $(G, \sigma_G)$ (i.e. $\#G < \infty$) and a non-negative integer $q \in \mathbb{Z}_{\geq 0}$, and consider only the $G$-colored graphs such that the number of edges ending at any vertex (called valency) is at most $q$. The isomorphism class $[S]$ of such a graph $S$ is called a $(G, q)$-configuration (or, a configuration). The set of all (connected) configurations is defined by:

(2.2.1) $\text{Conf} := \{G\text{-isomorphism classes of } G\text{-colored graphs such that the number of edges ending at any given vertex is at most } q\}$

(2.2.2) $\text{Conf}_0 := \{S \in \text{Conf} \mid S \text{ is connected}\}$.

The isomorphism class $[\emptyset]$ of an empty graph is contained in Conf but not in $\text{Conf}_0$. Sometimes it is convenient to exclude $[\emptyset]$ from Conf. So put:

(2.2.3) $\text{Conf}_+ := \text{Conf} \setminus \{[\emptyset]\}$.

**Remark.** To be exact, the set of configurations (2.2.1) should have been denoted by $\text{Conf}^{G, q}$. If there is a map $G \to G'$ between two color sets compatible with their involutions and an inequality $q \leq q'$, then there is a natural map $\text{Conf}^{G, q} \to \text{Conf}^{G', q'}$. Thus, for any inductive system $(G_n, q_n)_{n \in \mathbb{Z}_{>0}}$ (i.e. $G_n \to G_{n+1}$ and $q_n \leq q_{n+1}$ for $n$), we get the inductive limit $\lim_{n \to \infty} \text{Conf}^{G_n, q_n}$. In [S2], we used such limit set. However, in this paper, we fix $G$ and $q$, since the key limit processes (3.2.2) and (10.1.1) can be carried out for fixed $G$ and $q$. 
2.3 Semigroup structure and partial ordering structure on Conf.

We introduce the following two structures 1. and 2. on Conf.

1. The set Conf naturally has an abelian semigroup structure by putting
   \[ [S] \cdot [T] := [S \sqcup T] \quad \text{for } [S], [T] \in \text{Conf}, \]
   where \( S \sqcup T \) is the disjoint union of graphs \( S \) and \( T \) representing the isomorphism classes \([S]\) and \([T]\). The empty class \([\emptyset]\) plays the role of the unit and is denoted by 1. It is clear that Conf is freely generated by Conf_0. The power \( S^k \) or \([S]^k\) \((k \geq 0)\) denotes the class of a disjoint union \( S \sqcup \cdots \sqcup S \) of \( k \)-copies of \( S \).

2. The set Conf is partially ordered, where we define, for \( S \) and \( T \in \text{Conf} \),
   \[ S \leq T \quad \text{def.} \iff \text{there exist graphs } S \text{ and } T \text{ with } S = [S], T = [T] \text{ and } S \subset T. \]
   The unit 1 = \([\emptyset]\) is the unique minimal element in Conf by this ordering.

2.4 Covering coefficients.

For \( S_1, \ldots, S_m \) and \( S \in \text{Conf} \), we introduce a non-negative integer:

\[
(2.4.1) \quad \binom{S}{S_1, \ldots, S_m} := \# \left( \binom{S}{S_1, \ldots, S_m} \right) \in \mathbb{Z}_{\geq 0}
\]

and call it the covering coefficient, where \( \binom{S}{S_1, \ldots, S_m} \) is defined by the following:

i) Fix any \( G \)-graph \( S \) with \([S] = S\).

ii) Define a set:

\[
(2.4.2) \quad \binom{S}{S_1, \ldots, S_m} := \{ (S_1, \ldots, S_m) \mid S_i \subset S \text{ such that } [S_i] = S_i \text{ (i = 1, \ldots, m) and } \cup_{i=1}^{m} |S_i| = |S| \}.\]

iii) Show: an isomorphism \( S \simeq S' \) induces a bijection \( \binom{S}{S_1, \ldots, S_m} \simeq \binom{S'}{S_1', \ldots, S_m'} \).

Remark. In the definition \((2.4.2)\), one should notice that

i) Each \( S_i \) in \((2.4.2)\) should be a full subgraph of \( S \) (see \((2.1)\) Def. 2.).

ii) The union of the edges of \( S_i \) \((i = 1, \ldots, k)\) does not have to cover all edges of \( S \).

iii) The set of vertices \(|S_i| \) \((i = 1, \ldots, k)\) may overlap the set \(|S|\).

Example. Let \( X_1, X_2 \) be elements of Conf_0 with \( \sharp X_i = i \) for \( i = 1, 2 \). Then \( \binom{X_2}{X_1, X_1} = 0 \) and \( \binom{X_2}{X_1, X_1} = 2 \).

The covering coefficients are the most basic tool in the present paper. We shall give their elementary properties in \((2.5)\) and their two basic rules: the composition rule in \((2.6)\) and the decomposition rule in \((2.7)\).
2.5 Elementary properties for covering coefficients.

Some elementary properties of covering coefficients, as immediate consequences of the definition, are listed below. They will be used in the study of the Hopf algebra structure on the configuration algebra in §4.

i) \((S_{1},\ldots,S_{m}) = 0\) unless \(S_{i} \leq S\) for \(i = 1,\ldots,m\) and \(\sum S_{i} \geq S\).

ii) \((S_{1},\ldots,S_{m})\) is invariant by permutations of \(S_{i}\)’s.

iii) For \(1 \leq i \leq m\), one has an elimination rule:

\[
(2.5.1) \quad \left( \begin{array}{c} S \\ S_{1},\ldots,S_{i-1},[\emptyset],S_{i+1},\ldots,S_{m} \end{array} \right) = \left( \begin{array}{c} S \\ S_{1},\ldots,S_{i-1},S_{i+1},\ldots,S_{m} \end{array} \right).
\]

iv) For the case \(m = 0\), the covering coefficients are given by

\[
(2.5.2) \quad \left( \begin{array}{c} S \\ [\emptyset] \end{array} \right) = \begin{cases} 1 & \text{if } S = [\emptyset], \\ 0 & \text{otherwise}, \end{cases}
\]

v) For the case \(m = 1\), the covering coefficients are given by

\[
(2.5.3) \quad \left( \begin{array}{c} S \\ T \end{array} \right) = \begin{cases} 1 & \text{if } S = T, \\ 0 & \text{otherwise}, \end{cases}
\]

vi) For the case \(S = [\emptyset]\), the covering coefficients are given by

\[
(2.5.4) \quad \left( \begin{array}{c} [\emptyset] \\ S_{1},\ldots,S_{m} \end{array} \right) = \begin{cases} 1 & \text{if } \bigcup S_{i} = \emptyset, \\ 0 & \text{otherwise}. \end{cases}
\]

2.6 Composition rule.

**Assertion.** For \(S_{1},\ldots,S_{m},T_{1},\ldots,T_{n}, S \in \text{Conf} (m,n \in \mathbb{Z}_{\geq 0})\), one has

\[
(2.6.1) \quad \sum_{U \in \text{Conf}} \left( \begin{array}{c} U \\ S_{1},\ldots,S_{m} \end{array} \right) \left( \begin{array}{c} S \\ U,T_{1},\ldots,T_{n} \end{array} \right) = \left( \begin{array}{c} S \\ S_{1},\ldots,S_{m},T_{1},\ldots,T_{n} \end{array} \right).
\]

**Proof.** If \(m = 0\), then the formula reduces to 2.5 iii) and iv). Assume \(m \geq 1\) and consider the map

\[
\begin{array}{ccl}
S_{1},\ldots,S_{m},T_{1},\ldots,T_{n} & \mapsto & \bigsqcup_{U \in \text{Conf}} S_{1},\ldots,S_{m},T_{1},\ldots,T_{n} \\
S_{1},\ldots,S_{m},T_{1},\ldots,T_{n} & \mapsto & (\bigcup_{i=1}^{m} S_{i},T_{1},\ldots,T_{n}).
\end{array}
\]

Here, \(\bigcup_{i=1}^{m} S_{i}\) means the subgraph of \(S\) whose vertices are the union of the vertices of the \(S_{i}\) (\(i = 1,\ldots,m\)) (cf. 2.1 Def. 2.) and the class \([\bigcup_{i=1}^{m} S_{i}]\) is denoted by \(U\). The fiber over a point \((U,T_{1},\ldots,T_{n})\) is bijective to the set \((S_{1},\ldots,S_{m},T_{1},\ldots,T_{n})\) so that one has the bijection

\[
\left( \begin{array}{c} U \\ S_{1},\ldots,S_{m},T_{1},\ldots,T_{n} \end{array} \right) \sim \bigsqcup_{U \in \text{Conf}} \left( \begin{array}{c} U \\ S_{1},\ldots,S_{m} \end{array} \right) \left( \begin{array}{c} S \\ U,T_{1},\ldots,T_{n} \end{array} \right).
\]

**Note.** The LHS of 2.6.1 is a finite sum, since the only positive summands arise with \(U \leq S\) due to 2.5.1.
2.7 Decomposition rule.

**Assertion.** Let $m \in \mathbb{Z}_{\geq 0}$. For $S_1, \ldots, S_m, U$ and $V \in \text{Conf}$, one has

\[(2.7.1) \quad \left( U \cdot V \right)_{S_1, \ldots, S_m} = \sum_{R_1, T_1 \in \text{Conf}} \cdots \sum_{R_m, T_m \in \text{Conf}} \left( U_{R_1, \ldots, R_m} \right) \left( V_{T_1, \ldots, T_m} \right). \]

Here $R_i$ and $T_i \in \text{Conf}$ run over all possible decompositions of $S_i$ in $\text{Conf}$.

**Proof.** If $m = 0$, this is (2.5.2). Consider the map

\[
\left( U \cdot V \right)_{S_1, \ldots, S_m} \rightarrow \bigcup_{S_1 = R_1 \cdot T_1} \cdots \bigcup_{S_m = R_m \cdot T_m} \left( U_{R_1, \ldots, R_m} \right) \times \left( V_{T_1, \ldots, T_m} \right),
\]

\[
(S_1, \ldots, S_m) \mapsto \left( S_1 \cap U, \ldots, S_m \cap U \right) \times \left( S_1 \cap V, \ldots, S_m \cap V \right).
\]

One checks easily that the map is bijective. \[\square\]

**Note.** The RHS of (2.7.1) is a finite sum, since the only positive summands arises when $R_i \leq U$ and $T_i \leq V$.

§3. Configuration algebra.

We complete the semigroup ring $\mathbb{A} \cdot \text{Conf}$, where $\mathbb{A}$ is a commutative associative unitary algebra, by use of the adic topology with respect to the grading $\text{deg}(S) := \#S$, and call the completion the configuration algebra. It is a formal power series ring of infinitely many variables $S \in \text{Conf}_0$. We discuss several basic properties of the algebra, including topological tensor products.

3.1 The polynomial type configuration algebra $\mathbb{Z} \cdot \text{Conf}$.

The free abelian group generated by $\text{Conf}$:

\[(3.1.1) \quad Z \cdot \text{Conf} \]

naturally carries the structure of an algebra by the use of the semigroup structure on $\text{Conf}$ (recall 2.3), where $[\emptyset] = 1$ plays the role of the unit element. It is isomorphic to the free polynomial algebra generated by $\text{Conf}_0$, and hence is called the polynomial type configuration algebra. The algebra is graded by taking $\text{deg}(S) := \sharp(S)$ for $S \in \text{Conf}$, since one has additivity:

\[
(3.1.2) \quad \sharp(S \cdot T) = \sharp(S) + \sharp(T).
\]
3.2 The completed configuration algebra $Z \{\text{Conf}\}$.

The polynomial type algebra $Z \{\text{Conf}\}$ is not sufficiently large for our purposes, since it does not contain certain limit elements which we want to investigate (cf 4.6 Remark 3 and 6.4 Remark 2). Therefore, we localize the algebra by the completion with respect to the grading given in 3.1.

For $n \geq 0$, let us define an ideal in $Z \cdot \text{Conf}$

$$J_n := \text{the ideal generated by } \{S \in \text{Conf} \mid \sharp(S) \geq n\}.$$  

Taking $J_n$ as a fundamental system of neighborhoods of $0 \in Z \cdot \text{Conf}$, we define the adic topology on $Z \cdot \text{Conf}$ (see Remark below). The completion

$$(3.2.2) \quad Z \{\text{Conf}\} := \varprojlim_n Z \cdot \text{Conf} / J_n$$

will be called the completed configuration algebra, or, simply, the configuration algebra. More generally, for any commutative algebra $A$ with unit, we put

$$(3.2.3) \quad A \{\text{Conf}\} := \varprojlim_n A \cdot \text{Conf} / A J_n,$$

and call it the configuration algebra over $A$, or, simply, the configuration algebra. The augmentation ideal of the algebra is defined as

$$A \{\text{Conf}\}^+ := \text{the closed ideal generated by } \text{Conf}^+ = \text{the closure of } J_1 \text{ with respect to the adic topology.}$$

Let us give an explicit expression of an element of the configuration algebra by an infinite series. The quotient $A \cdot \text{Conf} / A J_n$ is naturally bijective to the free module $\prod_{S \in \text{Conf}, \sharp(S) < n} A \cdot S$ of finite rank. Taking the inverse limit of the bijection, we obtain

$$A \{\text{Conf}\} \simeq \prod_{S \in \text{Conf}} A \cdot S.$$  

In the other words, any element $f$ of the configuration algebra is expressed uniquely by an infinite series

$$(3.2.4) \quad f = \sum_{S \in \text{Conf}} S \cdot f_S$$

for some constants $f_S \in A$ for all $S \in \text{Conf}$. The coefficient $f_{\emptyset}$ of the unit element is called the constant term of $f$. The augmentation ideal is nothing but the collection of those $f$ having vanishing constant term.
Remark. The topology on $A[\text{Conf}]$ (except for the case $q = 0$) defined above is not equal to the topology defined by taking the powers of the augmentation ideal as the fundamental system of neighborhoods of 0. More precisely, for $n > 1$ and $q \neq 0$, the image of the product map:

\[(3.2.5) \quad (A[\text{Conf}])^n \rightarrow A\mathcal{J}_n\]

cannot generate (topologically) the target ideal on the RHS (the closure in $A[\text{Conf}]$ of the ideal $A\mathcal{J}_n = \{ f \in A[\text{Conf}] \mid \deg S \geq n \text{ for } f_S \neq 0 \}$), since there exists a connected configuration $S$ with $\deg S = n$, but $S$, as an element in $\mathcal{J}_n$, cannot be expressed as a function of elements of $\mathcal{J}_m$ for $m < n$. In this sense, the name “adic topology” is misused here.

The notation $A[\text{Conf}]$ should not be mistaken for the algebra of formal power series in Conf. In fact, it is the set of formal series in $\text{Conf}_0$.

3.3 Finite type element in the configuration algebra.

The support for the series $f$ (3.2.4) is defined as

\[(3.3.1) \quad \text{Supp}(f) := \{ S \in \text{Conf} \mid f_S \neq 0 \}.

Definition. An element $f$ of a configuration algebra is said to be of finite type if $\text{Supp}(f)$ is contained in a finitely generated semigroup in Conf. Note that $f$ being of finite type does not mean that $f$ is a finite sum, but means that it is expressed only by a finite number of “variables”. The subset of $A[\text{Conf}]$ consisting of all elements of finite type is denoted by $A[\text{Conf}]_{\text{finite}}$. The polynomial type configuration algebra $A \cdot \text{Conf}$ is a subalgebra of $A[\text{Conf}]_{\text{finite}}$.

3.4 Saturated subalgebras of the configuration algebra.

The configuration algebra is sometimes a bit too large. For later applications, we introduce a class of its subalgebras, called the saturated subalgebras.

A subset $P \subseteq \text{Conf}$ is called saturated if for $S \in P$, any $T \in \text{Conf}_0$ with $T \leq S$ belongs to $P$. For a saturated set $P$, let us define a subalgebra

\[(3.4.1) \quad A[P] := \{ f \in A[\text{Conf}] \mid \text{Supp}(f) \subseteq \text{the semigroup generated by } P \}.

We shall call a subalgebra of the configuration algebra of the form (3.4.1) for some saturated $P$ a saturated subalgebra. A saturated algebra $R$ is characterized by the properties: i) $R$ is a closed subalgebra under the adic topology of the configuration algebra, and ii) if $S \in \text{Supp}(f)$ for $f \in R$ then any connected component of $S$ (as a monomial) belongs to $R$. We call the set

\[(3.4.2) \quad \text{Supp}(R) := \bigcup_{f \in R} \text{Supp}(f)\]
the support of $R$. Obviously, $\text{Supp}(R)$ is the saturated subsemigroup of $\text{Conf}$
generated by $P$. The algebra $R$ is determined from $\text{Supp}(R)$.

It is clear that if $R$ is a saturated subalgebra of $\mathbb{A} [\text{Conf}]$ then $R \cap (\mathbb{A} \cdot \text{Conf})$
is a dense subalgebra of $R$ and that $R$ is naturally isomorphic to the completion
of $R \cap (\mathbb{A} \cdot \text{Conf})$ with respect to the induced adic topology.

**Example.** We give two typical examples of saturated sets.

1. For any element $S \in \text{Conf}$, we define its saturation by

   \[(3.4.3) \langle S \rangle := \{T \in \text{Conf} : T \leq S\} \]

2. Let $(\Gamma, G)$ be a Cayley graph of an infinite monoid $\Gamma$ with respect to
   a finite generating system $G$. Then, by choosing $G \cup G^{-1}$ as the color set and
   $q := \#(G \cup G^{-1})$ as the bound of valence, we define a saturated subset of $\text{Conf}$ by

   \[(3.4.4) \langle \Gamma, G \rangle := \{\text{isomorphism classes of finite subgraphs of } (\Gamma, G)\}.\]

   Obviously, the saturated subalgebra $\mathbb{A} [\langle S \rangle]$ consists only of finite type el-
ments, whereas the algebra $\mathbb{A} [\langle T, G \rangle]$ contains non-finite type elements. This
makes the latter algebra interesting when we study limit elements in §11.

3.5 Completed tensor product of the configuration algebra.

The tensor product over $\mathbb{A}$ of $m$-copies of $\mathbb{A} \cdot \text{Conf}$ for $m \in \mathbb{Z}_{\geq 0}$ is denoted
by $\otimes^m (\mathbb{A} \cdot \text{Conf})$. In this section, we describe the completed tensor product
$\hat{\otimes}^m \mathbb{A} [\text{Conf}]$ of the configuration algebra, $\mathbb{A} [\text{Conf}]$ is defined by the inverse limit

\[(3.5.1) \hat{\otimes}^m \mathbb{A} [\text{Conf}] := \lim_{\rightarrow \mathbb{N}} \otimes^m (\mathbb{A} \cdot \text{Conf})/(\otimes^m \mathbb{A} \mathcal{J})_n,\]

where $(\otimes^m \mathbb{A} \mathcal{J})_n$ is the ideal in $\otimes^m (\mathbb{A} \cdot \text{Conf})$ given by

\[(3.5.2) (\otimes^m \mathbb{A} \mathcal{J})_n := \sum_{n_1 + \cdots + n_m \geq n} \mathbb{A} \mathcal{J}_{n_1} \otimes \cdots \otimes \mathbb{A} \mathcal{J}_{n_m},\]

where $\hat{\otimes}^0 \mathbb{A} [\text{Conf}] = \mathbb{A}$ and $\hat{\otimes}^1 \mathbb{A} [\text{Conf}] = \mathbb{A} [\text{Conf}]$.

We list some basic properties of $\hat{\otimes}^m \mathbb{A} [\text{Conf}]$ (proofs are left to the reader).

i) Since $\cap_{n=0} (\mathbb{A} \mathcal{J} \hat{\otimes}^m)_n = \{0\}$, we have the natural inclusion map

\[(3.5.3) \otimes^m (\mathbb{A} \cdot \text{Conf}) \subset \hat{\otimes}^m (\mathbb{A} [\text{Conf}])\]

whose image is a dense subalgebra with respect to the $\mathbb{A} [\text{Conf}]$-adic topology.
ii) There is a natural algebra homomorphism

\[(3.5.4) \quad \otimes^m (A \llbracket \text{Conf} \rrbracket) \rightarrow \hat{\otimes}^m (A \llbracket \text{Conf} \rrbracket)\]

with a suitable universal property. The image of an element \(f_1 \otimes \cdots \otimes f_m\) is denoted by \(\hat{f}_1 \hat{\otimes} \cdots \hat{\otimes} \hat{f}_m\). We also denote it by \(f_1 \hat{\otimes} \cdots \hat{\otimes} f_m\) if \(f_i \in A \cdot \text{Conf} \) (\(i = 1, \ldots, m\)) because of i).

iii) If \(\Psi_i : \otimes^{m_i} (A \cdot \text{Conf}) \rightarrow \otimes^{n_i} (A \cdot \text{Conf}) \) (\(i = 1, \ldots, l\)) are continuous homomorphisms, then one has the completed homomorphism

\[(3.5.5) \quad \hat{\otimes}_{i=1}^l \Psi_i : \hat{\otimes}_{i=1}^l m_i (A \llbracket \text{Conf} \rrbracket) \rightarrow \hat{\otimes}_{i=1}^l n_i (A \llbracket \text{Conf} \rrbracket)\]

with some natural characterizing properties. In particular, the completed product map \(A \llbracket \text{Conf} \rrbracket \otimes A \llbracket \text{Conf} \rrbracket \rightarrow A \llbracket \text{Conf} \rrbracket\) is sometimes denoted by \(M\).

### 3.6 Exponential and logarithmic maps.

Let \(\varphi(t) = \sum_{n=0}^{\infty} \varphi_n t^n \in A \llbracket t \rrbracket\) be a formal power series in the indeterminate \(t\). Then the substitution of \(t\) by an element \(f\) of \(A \llbracket \text{Conf} \rrbracket\) to give \(\varphi(f) := \sum_{n=0}^{\infty} \varphi_n f^n \in A \llbracket \text{Conf} \rrbracket\) defines a map \(\varphi : A \llbracket \text{Conf} \rrbracket \rightarrow A \llbracket \text{Conf} \rrbracket\) (c.f. (3.2.5)). The map is equivariant with respect to any continuous endomorphism of the configuration algebra. The map can be restricted to any closed subalgebra of the configuration algebra to itself. If \(f\) is of finite type, then \(\varphi(f)\) is also of finite type.

In particular, if \(A\) contains \(\mathbb{Q}\), then we define the exponential, logarithmic and power (with an exponent \(c \in A\)) maps as follows:

\[(3.6.1) \quad \exp(f) : = \sum_{n=0}^{\infty} \frac{1}{n!} f^n \quad \text{for } f \in A \llbracket \text{Conf} \rrbracket_+ , \]

\[(3.6.2) \quad \log(1 + f) : = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} f^n \quad \text{for } f \in A \llbracket \text{Conf} \rrbracket_+ , \]

\[(3.6.3) \quad (1 + f)^c : = \sum_{n=0}^{\infty} \frac{c(c-1)\cdots(c-n+1)}{n!} f^n \quad \text{for } f \in A \llbracket \text{Conf} \rrbracket_+ . \]

They satisfy the standard functional relations: \(\exp(f + g) = \exp(f) \cdot \exp(g)\), \(\log((1 + f)(1 + g)) = \log(1 + f) + \log(1 + g)\), \((1 + f)^{c_1} \cdot (1 + f)^{c_2} = (1 + f)^{c_1+c_2}\) and \(\log((1 + f)^c) = c \cdot \log(1 + f)\).

**Fact.** Let \(A = \sum_{S \in \text{Conf}^+} S \cdot A_S\) and \(M = \sum_{S \in \text{Conf}^+} S \cdot M_S \in A \llbracket \text{Conf} \rrbracket\) by
related by $A = \exp(M)$ (⇔ $M = \log(A)$). Then their coefficients are related by

$$A_S = \sum_{m=0}^{\infty} \sum_{S_1, \ldots, S_m \in \text{Conf}_+} \frac{1}{k_1! \cdots k_m!} M_{S_1}^{k_1} \cdots M_{S_m}^{k_m},$$

and

$$M_S = \sum_{m=0}^{\infty} \sum_{S_1, \ldots, S_m \in \text{Conf}_+} \frac{(k_1 + \cdots + k_m - 1)!(-1)^{k_1+\cdots+k_m-1}}{k_1! \cdots k_m!} A_{S_1}^{k_1} \cdots A_{S_m}^{k_m}.$$  

Here the summation index runs over the set of all decompositions of $S$:

$$S = S_1^{k_1} \cdot \cdots \cdot S_m^{k_m}$$

for pairwise distinct $S_i \in \text{Conf}_+$ ($i = 1, \ldots, m$) (which may not necessarily be connected) and for positive integers $k_i \in \mathbb{Z}_{>0}$. Two decompositions $S_1^{k_1} \cdots S_m^{k_m}$ and $T_1^{l_1} \cdots T_n^{l_n}$ are regarded as the same if $m = n$ and there is a permutation $\sigma \in \mathfrak{S}_n$ such that $k_i = l_{\sigma(i)}$ and $S_i = T_{\sigma(i)}$ for $i = 1, \ldots, m$. The RHS’s of (3.6.4) and (3.6.5) are finite sums, since the $S_i$’s and $k_i$’s are bounded by $S$.

We omit the proof since it is a straightforward calculation of formal power series in the infinite generating system $\text{Conf}_0$.

**Corollary.** Let $A$ and $M \in \mathbb{A}[\text{Conf}]$ be related as above. Then one has

$$A_S = M_S \quad \forall S \in \text{Conf}_0.$$  

§4. The Hopf algebra structure

We construct a topological commutative Hopf algebra structure on the configuration algebra $\mathbb{A}[\text{Conf}]$. More precisely, we construct in §4.1 a sequence of co-products $\Phi_n$ ($n \in \mathbb{Z}_{\geq 0}$) by the use of the covering coefficients and, in §4.4, the antipode $\iota$, which together satisfy the axioms of a topological Hopf algebra.

### 4.1 Coproduct $\Phi_m$ for $m \in \mathbb{Z}_{\geq 0}$.

For a non-negative integer $m \in \mathbb{Z}_{\geq 0}$ and $U \in \text{Conf}$, define an element

$$\Phi_m(U) := \sum_{S_1 \in \text{Conf}} \cdots \sum_{S_m \in \text{Conf}} \left( S_1^{U}, S_2, \ldots, S_m \right) S_1 \otimes \cdots \otimes S_m$$

in the tensor product $\otimes^m(\mathbb{Z} \cdot \text{Conf})$ of $m$-copies of the polynomial type configuration algebra. Due to (2.5) v), one has,

$$\Phi_m([\emptyset]) = [\emptyset] \ (= 1).$$
The map $\Phi_m$ is \textit{multiplicative}. That is, for $U, V \in \text{Conf}$, one has
\begin{equation}
\Phi_m(U \cdot V) = \Phi_m(U) \cdot \Phi_m(V).
\end{equation}

\textit{Proof.} The decomposition rule (2.7.1) implies the formula. \hfill \square

Thus, the linear extension of $\Phi_m$ induces an algebra homomorphism from $\mathbb{Z} \cdot \text{Conf}$ to its $m$-tensor product $\otimes^m(\mathbb{Z} \cdot \text{Conf})$, which we denote by the same $\Phi_m$ and call this the \textit{$m$th coproduct}. The coproduct $\Phi_m$ can be further extended to a coproduct on the completed configuration algebra.

\textbf{Assertion.} 1. The \textit{$m$th coproduct} $\Phi_m$ ($m \in \mathbb{Z}_{\geq 0}$) on the polynomial type configuration algebra is continuous with respect to the adic topology. The induced homomorphism is denoted again by $\Phi_m$ and called the \textit{$m$th coproduct}:
\begin{equation}
\Phi_m : \mathbb{A}[\text{Conf}] \rightarrow \hat{\otimes}^m \mathbb{A}[\text{Conf}] := \mathbb{A}[\text{Conf}] \hat{\otimes} \cdots \hat{\otimes} \mathbb{A}[\text{Conf}]
\end{equation}

2. The completed homomorphism $\Phi_m$ has the multiplicativity
\begin{equation}
\Phi_m(f \cdot g) = \Phi_m(f) \cdot \Phi_m(g)
\end{equation}
for any $f, g \in \mathbb{A}[\text{Conf}]$.

3. Any saturated subalgebra $R$ of $\mathbb{A}[\text{Conf}]$ is preserved by $\Phi_m$:
\begin{equation}
\Phi_m(R) \subset \hat{\otimes}^m R.
\end{equation}

\textit{Proof.} 1. Recall the fundamental system $(\otimes^m \mathbb{A}\mathcal{J})_n$ (3.5.2) of neighborhoods of the $m$-tensor algebra $\otimes^m(\mathbb{Z} \cdot \text{Conf})$. Let us show the inclusion
\begin{equation}
\Phi_m(\mathbb{A}\mathcal{J}_n) \subset (\otimes^m \mathbb{A}\mathcal{J})_n
\end{equation}
for any $m, n \in \mathbb{Z}_{\geq 0}$. The ideal $\mathcal{J}_n$ is generated by $U \in \text{Conf}$ with $\deg(U) := \#U \geq n$, and $\Phi_m(U)$ is a sum of monomials $S_1 \otimes \cdots \otimes S_m$ for $S_i \in \text{Conf}$ such that $(\frac{S_1, \ldots, S_m}{U}) \neq 0$. We have $\#S_1 + \cdots + \#S_m \geq \#(U) \geq n$ because of (2.5) i), implying $\Phi_m(U) \in (\otimes^m \mathcal{J})_n$.

2. The multiplicativity of the monomials (4.1.3) implies the multiplicativity of the configuration algebra of polynomial type. This extends to multiplicativity on infinite series (3.2.4) because of the continuity of the product with respect to the adic topology.

3. Let $f$ be an element of $R$ and $f = \sum S f_S$ be its expansion. Then $\Phi_m(f)$ is a series of the form $\sum S_1 \otimes \cdots \otimes S_m(\frac{S_1, \ldots, S_m}{S}) f_S$. Thus, $(\frac{S_1, \ldots, S_m}{S}) f_S \neq$
0 implies each factor $S_i$ satisfies $S_i \leq S$ and $S \in \text{Supp}(f) \subset \text{Supp}(R)$. By the definition of saturation, $S_i \in \text{Supp}(R)$ and $\Phi_m(f) \in \hat{\otimes}^m R$.

**Co-commutativity** of the coproduct $\Phi_m$.

The symmetric group $S_m$ acts naturally on the $m$-tensors (3.5.1) by permuting the tensor factors. The image of $\Phi_m$ lies in the subalgebra consisting of $S_m$-invariant elements, because of (2.5 ii): $\Phi_m(\mathbb{A}[[\text{Conf}]]) \subset (\hat{\otimes}^m \mathbb{A}[[\text{Conf}]])^{S_m}$. We shall call this property the *co-commutativity* of the coproduct $\Phi_m$.

**4.2 Co-associativity**

**Assertion.** For $m, n \in \mathbb{Z}_{\geq 0}$, one has the formula:

\[(4.2.1) \quad (\hat{\otimes}^1 \cdots \hat{\otimes}^1 \hat{\otimes} \Phi_m) \circ \Phi_{n+1} = \Phi_{m+n}\]

**Proof.** This follows immediately from the composition rule (2.6.1).

Using the co-commutativity of $\Phi_2$, $\Phi_3$ can be expressed in two different ways:

\[(\Phi_2 \hat{\otimes} 1) \circ \Phi_2 = (1 \hat{\otimes} \Phi_2) \circ \Phi_2.\]

This equality is the *co-associativity* of the coproduct $\Phi_2$. More generally, $\Phi_m$ is expressed by a composition of $m - 1$ copies of $\Phi_2$’s in any order.

**4.3 The augmentation map $\Phi_0$.**

The augmentation map for the algebra is defined by $\Phi_0$ (recall (2.5.2)):

\[(4.3.1) \quad \text{aug} := \Phi_0 : \mathbb{A}[[\text{Conf}]] \rightarrow \mathbb{A}, \quad S \in \text{Conf}_+ \mapsto 0, \quad [\emptyset] \mapsto 1\]

**Assertion.** The map $\text{aug}$ is the co-unit with respect to the coproduct $\Phi_2$.

\[(4.3.2) \quad (\text{aug} \hat{\otimes} \text{id}) \circ \Phi_2 = \text{id}_Z[[\text{Conf}]].\]

**Proof.** This is the case $m = 0$ and $n = 1$ of the formula (4.2.1). Alternatively, for any $S \in \text{Conf}_+$, using (2.5 iii) and iv), one calculates: $(\text{aug} \hat{\otimes} \text{id}) \circ \Phi_2(S) = \sum_{T,U \in \text{Conf}} \left( S_{T,U} T \cdot \text{aug}(U) = \sum_{T \in \text{Conf}} S_{T,\emptyset} = S. \]
4.4 The antipodal map $\iota$

The coproduct and the co-unit exist both on the polynomial type and the completed configuration algebras. The co-inverse (or antipode), which we construct in the present section, exists only on the localized configuration algebra.

Assertion. There exists an $\mathbb{A}$-algebra endomorphism

\begin{equation}
\iota : \mathbb{A} \{\text{Conf}\} \to \mathbb{A} \{\text{Conf}\},
\end{equation}

satisfying the following properties i)-v).

i) $\iota$ is an involution. That is, $\iota$ is an automorphism with $\iota^2 = \text{id}_{\mathbb{A} \{\text{Conf}\}}$.

ii) $\iota$ is the co-inverse map with respect to the coproduct $\Phi_2$, that is,

\begin{equation}
M \circ (\iota \otimes \text{id}) \circ \Phi_2 = \text{aug}.
\end{equation}

where $M$ is the product defined on the completed tensor product (recall 3.5).

iii) $\iota$ is continuous with respect to the adic topology. More precisely,

\begin{equation}
\iota(J_n) \subset J_n
\end{equation}

for $n \in \mathbb{Z}_{\geq 0}$, where $\overline{J_n}$ is the closure of the ideal $J_n$ (3.2.1).

iv) $\iota$ leaves any saturated subalgebra of $\mathbb{A} \{\text{Conf}\}$ invariant.

v) Any $\mathbb{A}$-endomorphism of $\mathbb{A} \{\text{Conf}\}$ satisfying ii) and iii) is equal to $\iota$.

Proof. The proof is divided into two parts. In Part 1, we construct an endomorphism $\varphi$ of the algebra $\mathbb{A} \{\text{Conf}\}$, satisfying i), ii), iii) and iv). In Part 2, we show that any endomorphism $\psi$ of $\mathbb{A} \{\text{Conf}\}$ satisfying the properties ii) and iii) coincides with $\iota$.

Part 1. Let us fix a bijection $i \in \mathbb{Z}_{\geq 1} \mapsto S_i \in \text{Conf}_0$ such that if $S_i \leq S_j$ then $i \leq j$ (such linearization exists since one can linearize the partially ordered structure on the finite set of configurations for a fixed number of vertices). Note that this condition implies that the set $\{S_1, S_2, \ldots, S_i\}$ for $i \in \mathbb{Z}_{>0}$ is saturated in the sense of 3.4. Consider the increasing sequence $R_0 := \mathbb{A}, R_i := \mathbb{A}[S_1, S_2, \ldots, S_i] \ (i \in \mathbb{Z}_{>0})$ of saturated subalgebras of $\mathbb{A}[\text{Conf}]$. Let us show:

Claim: there exists a sequence $\{\varphi_i\}_{i \in \mathbb{Z}_{\geq 0}}$ of continuous endomorphisms $\varphi_i : R_i \to R_i$ satisfying the following relations:

a) $\varphi_i^2 = \text{id}_{R_i}$ for $i \in \mathbb{Z}_{\geq 0}$.

b) $\varphi_i |_{R_{i-1}} = \varphi_{i-1}$ for $i \in \mathbb{Z}_{\geq 1}$.

c) $M \circ (\varphi_i \cdot \text{id}) \circ \Phi_2 |_{R_i} = \text{aug} |_{R_i}$ for $i \in \mathbb{Z}_{\geq 0}$.

d) $\varphi_i(\overline{J_n} \cap R_i) \subset \overline{J_n} \cap R_i$ for $i \in \mathbb{Z}_{\geq 0}$ and for $n \in \mathbb{Z}_{\geq 0}$. 

c) \( \varphi_i(S_k) \in \mathbb{Z} \left[ \langle S_k \rangle \right] \) for \( 1 \leq k \leq i \) (see \( 3.4.1 \) and \( 3.4.3 \) for notation).

**Proof of Claim.** We construct the sequence \( \varphi_i \) inductively. Put \( \varphi_0 := \text{id}_A \).

For \( j \in \mathbb{Z}_{\geq 0} \), suppose that \( \varphi_0, \ldots, \varphi_j \) satisfying a)-e) for \( i \leq j \) are given.

For any given element \( X \in \mathbb{Z} \left[ \langle S_{j+1} \rangle \right] \cap \mathcal{F}(S_{j+1}) \), define an endomorphism \( \psi_X \) of \( R_j[S_{j+1}] \) by \( \psi_X|_{R_j} = \varphi_j \) and \( \psi_X(S_{j+1}) = X \). Since \( X \in \mathcal{F}(S_{j+1}) \), we have \( \psi_X(\mathcal{F}(S_{j+1}) \cap \mathcal{F}(S_{j+1})^\wedge) \subset \mathcal{F}(S_{j+1})^\wedge \in \mathbb{Z}_n \). Hence the endomorphism is continuous in the adic topology and is extended to an endomorphism of \( R_{j+1} = R_j[S] \). We denote the extended homomorphism again by \( \psi_X \).

Let us show that \( \varphi_{j+1} := \psi_X \) for a suitable choice of \( X \) satisfies a)-e) for \( i = j + 1 \). Actually, b), d) and e) are already satisfied by the construction. In order to satisfy a) and c), we have only to solve the following two equations on \( X \):

\[
a^*) \quad \psi_X(S_{j+1}) = S_{j+1} \quad \text{and} \quad c^*) \quad M \circ (\psi_X \otimes 1) \circ \Phi_2(S_{j+1}) = 0.
\]

In the following, we show an existence of a simultaneous solution of a)* and c)*.

c)* Let us write down the equation c)* explicitly by using \( 4.1.1 \).

\[
M \circ (\psi_X \otimes \text{id}) \circ \Phi_2(S_{j+1}) = \sum_{U, V \in \text{Conf}} \left( \frac{S_{j+1}}{U, V} \right) \psi_X(U) \cdot V = 0.
\]

The summation index \( (U, V) \) runs over the finite set \( \langle S_{j+1} \rangle \times \langle S_{j+1} \rangle \) (2.5 i)). Decompose the set into three pieces: \{\( S_{j+1} \)\} \times \{\( S_{j+1} \)\}, \{\( S_{j+1} \)\} \times \{\( S_{j+1} \)\}, \{\( S_{j+1} \)\} \times \{\( S_{j+1} \)\}, and \{\( S_{j+1} \)\} \times \{\( S_{j+1} \)\}. Since \( S_{j+1} \) is a monomial of \( S_k \)'s for \( 1 \leq k \leq j \). Therefore, by the induction hypothesis e), \( \varphi_j(A(S_{j+1}) - S_{j+1}) \in R_j \).

i) By definition \( 4.4.5 \), each term of \( A(S_{j+1}) - S_{j+1} \) is an element \( \langle S_{j+1} \rangle \setminus \{ S_{j+1} \} \), i.e. is a monomial of \( S_k \)'s for \( 1 \leq k \leq j \). Therefore, by the induction hypothesis e), \( \varphi_j(A(S_{j+1}) - S_{j+1}) \in R_j \).

ii) By the hypothesis d) for \( \varphi_j \), \( \varphi_j(U) \) belongs to \( \mathcal{F}(U) \cap \mathbb{Z} \left[ \langle U \rangle \right] \) for \( \forall U \leq S_{j+1} \) with \( U \neq S_{j+1} \). Hence, in view of 2.5 i), \( \frac{S_{j+1}}{U, V} \neq 0 \) implies \( \varphi_j(U) \cdot V \in \mathcal{F}(U) \), and, therefore, \( 4.5.5^* \) implies \( B(S_{j+1}) \in \mathcal{F}(S_{j+1}) \cap \mathbb{Z} \left[ \langle S_{j+1} \rangle \right] \).

iii) By definition \( 4.4.5 \), \( A(S_{j+1}) - 1 \) belongs to the augmentation ideal. Hence, in view of the inclusion \( 3.2.5 \), the sum \( \sum_{m \geq 0} (1 - A(S_{j+1}))^m \) converges in \( \mathbb{Z} \left[ \langle S_{j+1} \rangle \right] \) to the inverse \( A(S_{j+1})^{-1} \).
Therefore the equation (4.4.4) for $X$ has a unique solution in $\mathbb{Z}[[S_{j+1}]]$:

\[(4.4.6) \quad X := \frac{-1}{A(S_{j+1})} B(S_{j+1}) + \varphi_j (A(S_{j+1}) - S_{j+1}) \cdot S_{j+1}.)\]

As a consequence of the above Facts i) and ii), we have

*) The right hand side of (4.4.6) belongs to $\mathcal{J}_2(S_{j+1}) \cap \mathbb{Z}[[S_{j+1}]].$

This what we have asked for $X$ at the beginning. Thus, c)* is solved.

a) We need to show: $\psi^2_X(S_{j+1}) = S_{j+1}$ under the choice (4.4.6). Apply $\psi_X$ to the equality (4.4.4). Using the induction hypothesis a) and b), one gets

\[\psi^2_X(S_{j+1}) (\varphi_j(A(S_{j+1}) - S_{j+1})+\psi_X(S_{j+1})) + \varphi_j B(S_{j+1})+(A(S_{j+1}) - S_{j+1}) X = 0\]

Here, we have $\varphi_j B(S) = B(S)$, by applying the symmetry (2.5) ii) and the induction hypothesis a) to the expression (4.4.5)*. Subtract (4.4.4) from **):

\[(\psi^2_X(S_{j+1}) - S_{j+1}) (\varphi_j(A(S_{j+1}) - S_{j+1}) + \psi_X(S_{j+1})) = 0.\]

Since $A(S_{j+1}) - 1 \in \mathcal{J}_1$ and $\varphi_j(A(S_{j+1}) - S_{j+1}) + \psi_X(S_{j+1}) - 1 \in \mathcal{J}_1$, $\varphi_j(A(S_{j+1}) - S_{j+1}) + \psi_X(S_{j+1})$ is invertible in the algebra $R_{j+1}$. This implies $\psi^2_X(S_{j+1}) - S_{j+1} = 0$. That is, $\psi_X$ for (4.4.6) satisfies a)*.

Thus, by the choice $\varphi_{j+1} := \psi_X$, the induction step for $j+1$ is achieved. □

We define the endomorphism $\varphi$ of the subalgebra $R := \cup_{i=1}^{\infty} R_i$ by $\varphi[R_i] := \varphi_i$ for $i \in \mathbb{Z}_{\geq 0}$. Here, we note that $R$ comprise exactly the finite type elements, i.e. $R = A \otimes \mathbb{Z}[[\text{Conf}]]_{\text{finite}}$, which is dense in the configuration algebra. Then d) implies continuity of $\varphi$ on $R$, and therefore $\varphi$ extends to the full configuration algebra. The extended homomorphism, denoted by $\varphi$ again, satisfies involutivity since this is so on the dense subalgebra $R$. This implies $\varphi$ is invertible.

Finally in Part 1, let us show that $\varphi$ satisfies iv).

We remark that, for any element $S \in \text{Conf}$, one has $\varphi(S) \in \mathbb{Z}[[S]]$ (proof. apply e) to each connected component of $S$). Let $R$ be any saturated subalgebra of the configuration algebra. For any $f = \sum_S S f_S \in R$, by applying the above considerations, one has $\text{Supp}(\varphi(f)) \subset \cup_{f_S \neq 0} \text{Supp}(\varphi(S)) \subset \cup_{f_S \neq 0}$ semigroup generated by $\langle S \rangle \subset \text{Supp}(R)$. That is, $\varphi(f) \in R$ and $\varphi(R) \subset R$.

Part 2. Uniqueness of $\varphi$. Let $\psi$ be any endomorphism of the configuration algebra satisfying ii) and iii). Let $S_1, S_2, \cdots$ be the linear ordering of $\text{Conf}_0$ used in Part 1. We show that $\psi(S_j) = \varphi(S_j)$ by induction on $j \in \mathbb{Z}_{\geq 1}$. Let $j \in \mathbb{Z}_{\geq 0}$, and assume $\varphi(S_i) = \psi(S_i)$ for $1 \leq i \leq j$ (there is no assumption if $j = 0$). By ii), $\psi(S_{j+1})$ should satisfy the same equation (4.4.4) for $X$, where, by the induction hypothesis, one has the equality: $\varphi(A(S_{j+1}) - S_{j+1}) = \psi(A(S_{j+1}) - S_{j+1})$. 

\[\sum_{S_i} S_i f_{S_i} \in Z[[S]] \]
The uniqueness of the solution (4.4.6) implies \( \psi(S_i) = \varphi(S_i) \). This implies the coincidence of \( \varphi \) and \( \psi \) on \( \mathbb{Z} \cdot \text{Conf} \). Then, by the continuity iii), we have the coincidence of \( \varphi \) and \( \psi \) on the completed configuration algebra.

Equation (4.4.4) for \( n = 1 \) implies that \( \iota \) preserves the augmentation ideal of \( \mathbb{A} \left[ \text{Conf} \right] \). Hence, we have

\[
\text{aug} \circ \iota = \text{aug}.
\]

Let us state an important consequence of our construction.

**Assertion.** Any saturated subalgebra of the configuration algebra is a topological Hopf algebra. In particular, for any monoid \( \Gamma \) with a finite generating system \( G \) and commutative ring \( \mathbb{A} \) with a unit, \( \mathbb{A} \left[ \langle \Gamma, G \rangle \right] \) is a Hopf algebra.

**Proof.** We need only to remember that \( \Phi_m \) (\( m \geq 0 \)) and \( \iota \) preserve any saturated subalgebra (4.1 Assertion 3. and 4.4 Assertion iv)).

4.5 Some remarks on \( \iota \).

**Remark.** 1. In section 5., the functions \( \mathcal{A}(S) \) (\( S \in \text{Conf} \)) will be reintroduced and investigated. In particular we shall show the equality:

\[
\iota(\mathcal{A}(S)) \cdot \mathcal{A}(S) = 1
\]

for \( S \in \text{Conf} \). This can be also directly shown by use of (2.71) and (4.2.1). This relation gives a more natural definition of \( \iota \).

2. The polynomial ring \( \mathbb{A} \cdot \text{Conf} \) for any \( \mathbb{A} \) is not closed under the map \( \iota \). For example, let \( X \) (resp. \( Y \)) be a graph of one (resp. two) vertices. Then,

\[
\iota(X) = -\frac{X}{1+X} \quad \text{and} \quad \iota(Y) = \frac{-Y + 2X^2 + XY}{(1+X)(1+2X+Y)}.
\]

3. Because of above Remark 2, the localization: \( (\mathbb{Z} \cdot \text{Conf})_{\mathfrak{M}} = \{ f/g : f \in \mathbb{Z} \cdot \text{Conf}, g \in \mathfrak{M} \} \) for the multiplicative set \( \mathfrak{M} := \{ \mathcal{A}(S) : S \in \text{Conf} \} \) is the smallest necessary extension of the algebra \( \mathbb{Z} \cdot \text{Conf} \) to define \( \iota \). However, the space \( (\mathbb{Z} \cdot \text{Conf})_{\mathfrak{M}} \) is still too small for our later applications (see 6.3 Remark).

4. There is another coalgebra structure studied in combinatorics (\[\text{[R]}\]).

§5. Growth functions for configurations

For any \( S \in \text{Conf} \), the sum of isomorphism classes of all subgraphs of a graph representing \( S \) is denoted by \( \mathcal{A}(S) \). It is a group-like element in the Hopf algebra \( \mathbb{A} \left[ \text{Conf} \right] \) and shall play a fundamental role in the sequel. We shall call it a *growth function* (one shuld not confuse with the same terminology in [M]).
5.1 Growth functions

For \( S \) and \( T \in \text{Conf} \), we introduce a numerical invariant

\[
A(S, T) := \#A(S, T),
\]

by the following steps i)-iii).

i) Fix a graph \( T \), with \([T] = T\).

ii) Put

\[
A(S, T) := \#\{ S \mid S \text{ is a subgraph of } T \text{ such that } [S] = S\}.
\]

iii) Show that \( A(S, T) \simeq A(S, T') \) if \([T] = [T']\). (The proof is omitted.)

We shall call \( A(S, T) \) the growth coefficient of \( T \) at \( S \in \text{Conf} \).

\[
A([\emptyset], T) = 1 \quad \text{for} \quad T \in \text{Conf},
\]

\[
A(S, T) \neq 0 \quad \text{if and only if} \quad S \in \langle T \rangle.
\]

Let us introduce the generating polynomial of the growth coefficients:

\[
A(T) := \sum_{S \in \text{Conf}} S \cdot A(S, T),
\]

and call it the growth function of \( T \). In fact, this is a finite sum and \( A(T) \in \mathbb{Z} \cdot \text{Conf} \). The definition of \( A(T) \) can be reformulated as:

\[
A(T) = \sum_{S \in 2^T} [S],
\]

where \( 2^T \) denote the set of all subgraphs of \( T \) (cf. \( 2.1 \) Definition 2.).

The following multiplicativity follows immediately from the expression (5.1.6). For \( T_1 \) and \( T_2 \in \text{Conf} \)

\[
A(T_1 \cdot T_2) = A(T_1) \cdot A(T_2).
\]

Remark. 1. By comparing the definition (5.1.1) with (2.4.1), we see immediately \( A(S, T) = \binom{T}{T, S} \) for \( S \) and \( T \in \text{Conf} \). Hence the two definitions (4.4.5) and (5.1.5) for \( A(T) \) coincide.

2. By definition (5.1.1), we have additivity:

\[
A(S, T_1 \cdot T_2) = A(S, T_1) + A(S, T_2)
\]

for \( S \in \text{Conf}_0 \) and \( T_i \in \text{Conf} \).
5.2 A numerical bound of the growth coefficients

In our later study on the existence of limit elements in §10, the following estimates on the growth rates of growth coefficients play a crucial role.

Lemma. For $S, T \in \text{Conf}$, we have

$$A(S, T) \leq \frac{1}{\# \text{Aut}(S)} \cdot T^{n(S)} \cdot (q - 1)^{q - n(S)}.$$  \hfill (5.2.1)

Here $n(S) := \sharp$ of connected components of $S$, $q$ is the upper-bound of the number of edges at each vertex of $T$ (recall §2.2), and $\text{Aut}(S)$ means the isomorphism class of $\text{Aut}(S)$ for a representative $S$ of $S$ and we put $\# \text{Aut}(S) := \# \text{Aut}(S)$.

Note. In the original version [S2], the factor $q - 1$ in (5.2.1) was $q$. The author is grateful to the readers pointing out this improvement.

Proof. Let $S$ and $T$ be representatives of the $G$-colored graphs $S$ and $T$ respectively. We divide the proof into three steps.

i) Assume $S$ is connected. Let us show:

$$A(S, T) \leq \frac{1}{\# \text{Aut}(S)} \cdot T : (q - 1)^{q - 1}.$$  \hfill (5.2.2)

Proof. Let $S_1, \ldots, S_a$ be an increasing sequence of connected subgraphs of $S$ such that $\sharp S_i = i$ ($i = 1, \ldots, a = \sharp S$). Put $\text{Emb}(S_i, T) := \{ \varphi : S_i \to T \mid \text{embeddings as a } G\text{-colored graph} \}$. Then, for $i \geq 2$, the natural restriction map $\text{Emb}(S_i, T) \to \text{Emb}(S_{i-1}, T)$ has at most $q - 1$ points in its fiber. Hence

$$\sharp \text{Emb}(S_i, T) \leq (q - 1) \cdot \sharp \text{Emb}(S_{i-1}, T) \quad (i = 2, \ldots, a).$$

On the other hand, since

$$A(S, T) = \sharp \text{Emb}(S, T)/\# \text{Aut}(S),$$

one has the inequality:

$$A(S, T) = \sharp \text{Emb}(S_a, T)/\# \text{Aut}(S_a)$$

$$\leq (q - 1)^{a - 1} \cdot \sharp \text{Emb}(S_1, T)/\# \text{Aut}(S_a) = (q - 1)^{a - 1} \cdot T/\# \text{Aut}(S).$$

ii) Assume that $S$ decomposes as: $S = S_1^{k_1} \cdots S_m^{k_m}$ for pairwise distinct $S_i \in \text{Conf}_0$ ($i = 1, \cdots, m$) so that $\sum_{i=1}^{m} k_i = n(S)$. Let us show

$$A(S, T) \leq \frac{1}{k_1! \cdots k_m!} \prod_{i=1}^{m} A(S_i, T)^{k_i},$$  \hfill (5.2.3)

Proof. For $1 \leq i \leq m$, the subgraph of $S \in A(S, T)$ corresponding to the factor $S_i^{k_i}$, denoted by $S_i^{k_i}$, defines an off-diagonal element of $(\prod_{i=1}^{m} A(S_i, T))/S_i^{k_i}$,
where $\mathcal{G}_{k_i}$ is the symmetric group of $k_i$ elements acting freely on the set of off-diagonal elements. Then, the association $\mathcal{S} \mapsto (\mathcal{S}|_{S_i^{k_i}})_{i=1}^m$ defines an embedding:
\[ \Lambda(S, T) \to \prod_{i=1}^m \left( \left( \prod_{k_i} \Lambda(S_i, T) \right) / \mathcal{G}_{k_i} \right) \]
into the off-diagonal part.

iii) Let $S$ be as in ii). Then, $\text{Aut}(S) = \prod_{i=1}^m \text{Aut}(S_i^{k_i})$ and each factor $\text{Aut}(S_i^{k_i})$ is a wreath direct product of $\text{Aut}(S_i)$ and $\mathcal{G}_{k_i}$. Then (5.2.1) is a consequence of a combination of (5.2.2) and (5.2.3).

This completes the proof of the Lemma.

\textbf{5.3 Product-expansion formula for growth coefficients}

The coefficients of a growth function of $T$ are not algebraically independent.

\textbf{Lemma.} Let $S_1, \ldots, S_m$ $(m \geq 0)$ and $T \in \text{Conf}$ be given. Then,
\begin{equation}
\prod_{i=1}^m A(S_i, T) = \sum_{S \in \text{Conf}} \left( \left( \prod_{i=1}^m S \right) A(S, T) \right).
\end{equation}

\textbf{Proof.} Let $\mathcal{T}$ be a graph representing $T$. For $m \in \mathbb{Z}_{\geq 0}$, consider a map
\[(S_1, \ldots, S_m) \in \prod_{i=1}^m A(S_i, T) \mapsto \mathcal{S} := \bigcup_{i=1}^m S_i \in 2^\mathcal{T},
\]
whose fiber over $\mathcal{S}$ is $(S_1, \ldots, S_m)$ so that one has the decomposition
\[ \prod_{i=1}^m A(S_i, T) \simeq \bigcup_{S \in 2^\mathcal{T}} \left( \left( \prod_{i=1}^m S \right) \right). \]
By counting the cardinality of the both sides, one obtains the formula.

\textbf{Remark.} The formula (5.3.1) is trivial for $m \in \{0, 1\}$, and can be reduced to the case $m = 2$ for $m \geq 2$ by an induction on $m$ as follows.

Multiply $A(S_{m+1}, T)$ to (5.3.1) and apply the formula for $m = 2$.
\begin{align*}
\prod_{i=1}^{m+1} A(S_i, T) &= \sum_{S \in \text{Conf}} \left( \left( \prod_{i=1}^m S \right) A(S, T) A(S_{m+1}, T) \right) \\
&= \sum_{S \in \text{Conf}} \left( \left( \prod_{i=1}^m S \right) \sum_{U \in \text{Conf}} \left( \prod_{i=1}^m U \right) A(U, T) \right).
\end{align*}
Using the composition rule (2.6.1), this is equal to
\[ \sum_{U \in \text{Conf}} \left( \left( \prod_{i=1}^m U \right) A(U, T). \right]
5.4 Group-like property of the growth function

An element $g \in \mathbb{A}[\text{Conf}]$ is called group-like if it satisfies

$$(5.4.1) \quad \Phi_m(g) = g \otimes \cdots \otimes g$$

for all $m \in \mathbb{Z}_{\geq 0}$. This in particular implies the conditions $\Phi_0(g) = 1$ and $\iota(g) = g^{-1}$ (c.f. (4.3.1) and (4.4.2)). For any group-like elements $g$ and $h$, the power product $g^a h^b$ for $a, b \in \mathbb{A}$ (c.f. (3.6.3)) is also group-like. We put

$$(5.4.2) \quad \mathfrak{G}_\mathbb{A} := \{ \text{the set of all group-like elements in } \mathbb{A}[\text{Conf}] \}$$

$$(5.4.3) \quad \mathfrak{G}_\mathbb{A},_{\text{finite}} := \{ g \in \mathfrak{G}_\mathbb{A} | g \text{ is of finite type.} \}$$

Lemma. The generating polynomial $A(T)$ for any $T \in \text{Conf}$ is group-like. That is, for any $m \in \mathbb{Z}_{\geq 0}$ and $T \in \text{Conf}$, we have

$$(5.4.4) \quad A(T) \otimes \cdots \otimes A(T) = \Phi_m(A(T)).$$

Proof. By the definition of $A(T)$ (5.1.3), the tensor product of $m$-copies

*)

$A(T) \otimes \cdots \otimes A(T)$

can be expanded into a sum of $m$ variables $S_1, \ldots, S_m$:

***)

$\sum_{S_1 \in \text{Conf}} \cdots \sum_{S_m \in \text{Conf}} S_1 \otimes \cdots \otimes S_m \left( \prod_{i=1}^{m} A(S_i, T) \right)$.

By use of the product-expansion formula (5.3.1), this is equal to

$\sum_{S_1 \in \text{Conf}} \cdots \sum_{S_m \in \text{Conf}} S_1 \otimes \cdots \otimes S_m \left( \sum_{S \in \text{Conf}} \left( \sum_{S_1, \ldots, S_m} S \right) A(S, T) \right)$

Recalling the definition of the map $\Phi_m$ (4.1.4), this is equal to

****

$\sum_{S \in \text{Conf}} \Phi_m(S) \cdot A(S, T) = \Phi_m \left( \sum_{S \in \text{Conf}} S \cdot A(S, T) \right) = \Phi_m(A(T)).$

5.5 A characterization of the antipode.

Equation (5.4.4) provides formulae,

(5.5.1) \quad $\nu(A(T)) A(T) = 1$ for $T \in \text{Conf}$,

(5.5.2) \quad $\Phi_m \circ \nu = (\nu \otimes \cdots \otimes \nu) \circ \Phi_m$ for $m \in \mathbb{Z}_{\geq 0}$.
Proof of (5.5.1). Apply (5.4.1) to \((\iota \cdot 1) \circ \Phi_2(T) = \text{aug}(T)\) (4.4.2).

Proof of (5.5.2). It is enough to show the case \(m = 2\) due to (4.2.1). Apply \(\Phi_2\) to (5.5.1). Recalling (5.4.1), one obtains a relation
\[
\Phi_2(\iota(A(T)) \cdot (A(T) \otimes (A(T))) = 1 .
\]
Multiply \(\iota(A(T))\) and apply again (5.5.1) so that one obtains
\[
\Phi_2(\iota(A(T))) = \iota(A(T) \otimes (A(T))) = (\iota \otimes \iota)(A(T) \otimes A(T)) = (\iota \otimes \iota)\Phi_2(A(T)).
\]
Thus (5.5.2) is true for \(A(T)\) \((T \in \text{Conf})\). Since \(A(T)\) \((T \in \text{Conf})\) span \(\mathbb{A} \cdot \text{Conf}\), which is dense in the whole algebra, (5.5.2) holds on \(\mathbb{A} \cdot \text{Conf}\).

§6. The logarithmic growth function

The growth coefficients \(A(S,T)\) in \(S \in \langle T \rangle\) were bounded from above in (5.2.1). However in the sequel, we also need to bound its lower terms. This is achieved by introducing a logarithmic growth coefficient \(M(S,T) \in \mathbb{Q}\) in \(S \in \langle T \rangle\), and showing linear relations (6.2.2).

6.1 The logarithmic growth coefficient

For \(T \in \text{Conf}\), define the logarithm of the growth function:
\[
M(T) : = \log(A(T)),
\]
in \(\mathbb{Q} \llbracket \langle T \rangle \rrbracket\) (cf (6.1.5) and (3.6.2)). Expand \(M(T)\) in a series
\[
M(T) = \sum_{S \in \text{Conf}} S \cdot M(S,T).
\]
The coefficient \(M(S,T)\) is the logarithmic growth coefficient at \(S \in \langle T \rangle\).

By definition, \(M(T)\) does not have a constant term, i.e.
\[
M([\emptyset], T) : = 0 \quad \text{for} \quad T \in \text{Conf}.
\]

For later applications, we write the explicit relations among growth-functions
and logarithmic growth-functions (cf. (3.6.4) and (3.6.5)).

\begin{align*}
\text{(6.1.4)} \quad A(S, T) &= \sum_{S = S_1^{k_1} \cdots S_m^{k_m}} \frac{1}{k_1! \cdots k_m!} M(S_1, T)^{k_1} \cdots A(S_m, T)^{k_m} \\
\text{(6.1.5)} \quad M(S, T) &= \sum_{S = S_1^{k_1} \cdots S_m^{k_m}} \frac{(k_1 + \cdots + k_m - 1)!(-1)^{k_1+\cdots+k_m-1}}{k_1! \cdots k_m!} \\
&\quad \times A(S_1, T)^{k_1} \cdots A(S_m, T)^{k_m}.
\end{align*}

Remark. 1. From the formula, we see that for a connected \( S \in \text{Conf}_0 \),
(6.1.6)

\[ A(S, T) = M(S, T). \]

That is, the logarithmic growth coefficients coincide with the growth coefficients
at connected configurations. This elementary fact shall be used repeatedly.

2. The multiplicativity of \( A(T) \) (5.1.7) implies the additivity

\[ \mathcal{M}(T_1 \cdot T_2) = \mathcal{M}(T_1) + \mathcal{M}(T_2) \]
for \( T_i \in \text{Conf} \) and hence the additivity:

\[ (6.1.7)^* \quad M(S, T_1 \cdot T_2) = M(S, T_1) + M(S, T_2) \quad \text{for} \quad S \in \text{Conf}. \]

3. The invertibility (5.5.1) implies

\[ (6.1.8) \quad \iota(\mathcal{M}(T)) = -\mathcal{M}(T). \]

6.2 The linear dependence relations on the coefficients

Lemma. The polynomial relation (5.4.4) implies the linear relation:

\[ (6.2.1) \quad \sum_{i=1}^m 1 \otimes \cdots \otimes 1 \otimes \mathcal{M}(T) \otimes 1 \otimes \cdots \otimes 1 = \Phi_m(\mathcal{M}(T)), \]
on the logarithmic growth-function for \( T \in \text{Conf} \) and \( m \in \mathbb{Z}_{\geq 0} \).

Proof. Put \( \mathcal{M}_i(T) := 1 \otimes \cdots \otimes 1 \otimes \mathcal{M}(T) \otimes 1 \otimes \cdots \otimes 1 \) so that \( \exp(\mathcal{M}_i(T)) = 1 \otimes \cdots \otimes 1 \otimes A(T) \otimes 1 \otimes \cdots \otimes 1 \). Then (5.4.4) can be rewritten as:

\[ (6.2.1)^* \quad \exp(\mathcal{M}_1(T)) \cdot \ldots \cdot \exp(\mathcal{M}_m(T)) = \Phi_m(\exp(\mathcal{M}(T))) \]
where the left hand side is equal to \( \exp(\mathcal{M}_1(T) + \cdots + \mathcal{M}_m(T)) \) due to the commutativity of the \( \mathcal{M}_i \)'s and the addition rule for \( \exp \). The right hand side of \( \ast \)
can be rewritten as \( \Phi_m(\exp(\mathcal{M}(T))) = \Phi_m\left(\sum_{n=0}^{\infty} \frac{1}{n!} \mathcal{M}(T)^n\right) = \sum_{n=0}^{\infty} \frac{1}{n!} \Phi_m(\mathcal{M}(T))^n = \exp(\Phi_m(\mathcal{M}(T))) \). By taking the logarithm of both sides, we obtain (6.2.1).

**Corollary.** Let \( m \geq 2 \). For \( S_1, \ldots, S_m \in \text{Conf}_+ \) and \( T \in \text{Conf} \),

\[
\sum_{S \in \text{Conf}} \left( \sum_{S_i} M(S, T) \right) = 0.
\]

**Proof.** Expand both sides of (6.2.1) in a series of the variables \( S_i := 1 \otimes \cdots \otimes 1 \otimes S_i \otimes 1 \otimes \cdots \otimes 1 \) \( (i = 1, \ldots, m) \). Since the left hand side of (6.2.1) does not have a mixed term \( S_1 \otimes \cdots \otimes S_m \) for \( S_i \in \text{Conf}_+ \) and \( m \geq 2 \), the corresponding coefficients in the right hand side vanish. By (4.1.1) and (6.1.2), this implies the formula (6.2.2).

**Remark.** 1. The formula (6.2.2) is reduced to the case \( m = 2 \) with \( S_i \neq \emptyset \) \( (i = 1, 2) \) by induction on \( m \). Recalling the composition rule (2.6)

\[
\sum_S \left( \sum_{U} (S_1, \ldots, S_m) M(S, T) \right) = \sum_S \left( \sum_{U} (S_1, \ldots, S_{m-1}) (U, S_m) M(S, T) \right)
\]

\[
eq \sum_{U} (S_1, \ldots, S_{m-1}) \left( \sum_S (U, S_m) M(S, T) \right) + (S_1, \ldots, S_{m-1}) \left( \sum_S (\emptyset, S_m) M(S, T) \right)
\]

\[= 0 + 0 = 0.
\]

2. The linear dependence relations (6.2.2) among \( M(S, T) \)'s for \( S \in \text{Conf} \) are the key facts of the present paper. The Hopf algebra structure was introduced only to deduce this relation. We shall solve this relation in (8.3.2) by use of kabi coefficients, which we introduce in the next paragraph § 7.

### 6.3 Lie-like elements

An element \( \mathcal{M} \) satisfying (6.2.1) has a name in Hopf algebra theory [9].

**Definition.** Let \( \mathbb{A} \) be a commutative algebra with a unit. An element \( \mathcal{M} \) of \( \mathbb{A}[\text{Conf}] \) is called **Lie-like** if it satisfies the relation:

\[
\Phi_m(\mathcal{M}) = \sum_{i=1}^{m} \mathcal{M}^i \otimes \cdots \otimes 1 \otimes \cdots \otimes 1
\]

for all \( m \in \mathbb{Z}_{\geq 0} \). This, in particular, implies the conditions \( \Phi_0(\mathcal{M}) = 0 \) and \( \iota(\mathcal{M}) + \mathcal{M} = 0 \) (c.f. (4.3.1) and (4.4.2)). The linear combinations (over \( \mathbb{A} \)) of
Lie-like elements are also Lie-like. We put

\[(6.3.2) \quad \mathcal{L}_A := \{ \text{all Lie-like elements in } A \left[ \text{Conf} \right] \}, \]

and

\[(6.3.3) \quad \mathcal{L}_{A, \text{finite}} := \{ M \in \mathcal{L}_A \mid M \text{ is of finite type} \}. \]

In this terminology, \((6.2)\) Lemma can be rewritten as: suppose \(Q \subset A\), then one has \(\mathcal{M}(T) \in \mathcal{L}_{A, \text{finite}}\) for \(T \in \text{Conf}\).

\textbf{Remark.} We shall see in \(8.4\) that \(\mathcal{L}_R\) is essentially an extension of \(\mathcal{L}_{R, \text{finite}}\) by a space \(\mathcal{L}_{R, \infty}\), which is the main objective of the present paper. On the other hand, one has \(\mathcal{L}_A \cap (A \cdot \text{Conf})_{2R} \subset \mathcal{L}_{A, \text{finite}}\) (actually equality holds, see §\(8\)), since \((A \cdot \text{Conf})_{2R}\) consists only of finite type elements.

\section{Kabi coefficients}

We describe the inverse matrix of the infinite matrix \(A := (A(S, T))_{S, T \in \text{Conf}_0}\) explicitly in terms of kabi coefficients introduced in \((7.2)\). The construction shows that the inverse matrix has only bounded number of nonzero entries \((7.5)\). This fact leads to the comparison of the two topologies on \(\mathcal{L}_{A, \text{finite}}\), which plays a key role in the sequel in construction of the infinite space \(\mathcal{L}_{A, \infty}\).

\subsection{The unipotency of \(A\)}

The matrix \(A\) is unipotent in the sense that i) \(A(S, S) = 1\) and ii) \(A(S, T) = 0\) for \(S \not\preceq T\) \(\Box\). Then a matrix \(A^{-1} := E + A^* + A^{*2} + A^{*3} + \cdots\), where \(E := (\delta(U, V))_{U, V \in \text{Conf}_0}\) and \(A^* := E - A\), is well defined. Precisely,

\[
A^{-1}(S, T) = \begin{cases} 
0 & \text{for } S \not\preceq T, \\
1 & \text{for } S = T, \\
\sum_{k>0} (-1)^k \left( \sum_{S=S_0<\cdots<S_k=T} (\prod_{i=1}^{k} A(S_{i-1}, S_i)) \right) & \text{for } S < T.
\end{cases}
\]

The matrix \(A^{-1}\) is unipotent in the same sense as \(A\), and, hence, the products \(A^{-1} \cdot A\) and \(A \cdot A^{-1}\) are well defined and are equal to \(E\).

\subsection{Kabi coefficients}

\textbf{Definition.} 1. A graph \(U\) is called a \textit{kabi} over its subgraph \(S\) if for all \(x \in U \setminus S\), there exists \(y \in S\) such that \((x, y)\) is an edge.
2. Let $U \in \text{Conf}_0$ and let $U$ be a graph with $[U] = U$. For $S \in \text{Conf}_0$, put

$$K(S, U) : = \{ S \mid S \subset U \text{ such that } [S] = S \text{ and } U \text{ is kabi over } S \},$$

(7.2.1)

$$K(S, U) : = \#K(S, U).$$

(7.2.2)

We call $K(S, U)$ a \textit{kabi-coefficient}. The definition of the coefficient does not depend on the choice of $U$. If $K(S, U) \neq 0$, we say that $U$ has a kabi structure over $S$ or simply $U$ is kabi over $S$.

Directly from definition, we have

$$K(S, U) = 0 \text{ for } S \nsubseteq U,$$

(7.2.3)

$$K(S, S) = 1 \text{ for } S \in \text{Conf}_0.$$

(7.2.4)

Note. The word “kabi” means “mold” in Japanese.

### 7.3 Kabi inversion formula

**Lemma.** For $S \in \text{Conf}_0$ and $T \in \text{Conf}$, one has the formula:

$$\sum_{U \in \text{Conf}_0} (-1)^{\#U - \#S} K(S, U) \cdot A(U, T) = \delta(S, T),$$

(7.3.1)

where $\delta(S, T)$ means the \# of connected components of $T$ isomorphic to $S$.

**Proof.** The summation index $U$ on the left hand side runs over the range $S \leq U \leq T$ (otherwise $K(S, U) \cdot A(U, T) = 0$). Hence if $S \nsubseteq T$, then the sum equals 0. If $S = T$, the only term in the sum is $K(S, S)A(S, S)$ which equals 1.

Let $S \in \text{Conf}_0$ and $T \in \text{Conf}$. Assume $S \leq T$ and $S \neq T$. Let $T$ be a $G$-colored graph with $T = [T]$. Applying the definition of $K(S, U)$ and $A(U, T)$ (cf. (5.1.1)), the left hand side of (7.3.1) can be rewritten as

$$\sum_{U \in \text{Conf}_0} (-1)^{\#U - \#S} K(S, U) \cdot \#\Lambda(U, T)$$

$$= \sum_{U \in \text{Conf}_0} (-1)^{\#U - \#S} K(S, U) \cdot \#\{ U \mid U \subset T \text{ such that } [U] = U \}$$

$$= \sum_{U \in \text{Conf}_0} (-1)^{\#U - \#S} \#\left\{ (S, U) \mid S \subset U \subset T \text{ such that } [S] = S, [U] = U \text{ and } U \text{ is kabi over } S \right\}$$

Now we make a re-summation of this by fixing the subgraph $S$ in $T$.

$$= \sum_{S \in \Lambda(S, T)} \left( \sum_{U \in \text{Conf}_0} (-1)^{\#U - \#S} \#\left\{ U \mid S \subset U \subset T \text{ such that } [U] \simeq U \text{ and } U \text{ is a kabi over } S. \right\} \right)$$
For a fixed subgraph $\mathcal{S}$ of $\mathcal{T}$, let $U_{\text{max}}$ be the maximal subgraph of $\mathcal{T}$ such that $U_{\text{max}}$ is a kabi over $\mathcal{S}$, i.e. $U_{\text{max}}$ consists of vertices of $\mathcal{T}$, which are either in $\mathcal{S}$ or connected to $\mathcal{S}$ by an edge. Then a subgraph $U$ of $\mathcal{T}$ becomes a kabi over $\mathcal{S}$, if and only if it is a subgraph of $U_{\text{max}}$ containing $\mathcal{S}$. Hence the sum is equal to
\[
\sum_{\mathcal{S} \in \text{Conf}_0} (\mathcal{A}(\mathcal{S}, \mathcal{T})) = \sum_{\mathcal{S} \in \text{Conf}_0} \left( \sum_{\mathcal{W} \subset U_{\text{max}} \setminus \mathcal{S}} (-1)^{\# \mathcal{W}} \right).
\]
where the last summation index $\mathcal{W}$ runs over all subsets of $U_{\text{max}} \setminus \mathcal{S}$. Hence the summation in the parenthesis becomes $1$ or $0$ according to whether $U_{\text{max}} \setminus \mathcal{S}$ is $\emptyset$ or not. It is clear that $U_{\text{max}} \setminus \mathcal{S} = \emptyset$ is equivalent to the fact that $\mathcal{S}$ is a connected component of $\mathcal{T}$. Hence the sum is equal to $\delta(\mathcal{S}, \mathcal{T})$.

7.4 Corollaries to the inversion formula.

The left inverse matrix of $\mathcal{A} := (A(\mathcal{S}, \mathcal{T}))_{\mathcal{S}, \mathcal{T} \in \text{Conf}_0}$ is given by
\[
(7.4.1) \quad \mathcal{A}^{-1} = \left( (-1)^{\mathcal{T} - \# \mathcal{S}} K(\mathcal{S}, \mathcal{T}) \right)_{\mathcal{S}, \mathcal{T} \in \text{Conf}_0}.
\]
Since the left inverse matrix of $\mathcal{A}$ coincides with the right inverse, one has
\[
(7.4.2) \quad \sum_{\mathcal{U} \in \text{Conf}_0} (-1)^{\mathcal{T} - \# \mathcal{U}} A(\mathcal{S}, \mathcal{U}) \cdot K(\mathcal{U}, \mathcal{T}) = \delta(\mathcal{S}, \mathcal{T})
\]
for $\mathcal{S} \in \text{Conf}_0$. Specializing $\mathcal{S}$ in (7.4.2) to $\mathcal{pt} := \text{[one point graph]}$, one gets,
\[
(7.4.3) \quad \sum_{\mathcal{U} \in \text{Conf}_0} (-1)^{\# \mathcal{U}} K(\mathcal{U}, \mathcal{T}) = (-1)^{\# \mathcal{T}} \delta(\mathcal{pt}, \mathcal{T}).
\]

7.5 Boundedness of non-zero entries of $K$

One of the most important consequences of (7.4.1) is the boundedness of the non-zero entries of the matrix $\mathcal{A}^{-1}$, as follows.

Suppose $K(\mathcal{S}, \mathcal{T}) \neq 0$. Then, by definition, $\mathcal{T}$ must have at least one structure of kabi over $\mathcal{S}$. This implies that for each fixed $\mathcal{S}$ and $q \geq 0$, there are only a finite number of $\mathcal{T} \in \text{Conf}_0$ with $K(\mathcal{S}, \mathcal{T}) \neq 0$. Precisely,

**Assertion.** For $\mathcal{S} \in \text{Conf}_0$, $K(\mathcal{S}, \mathcal{T}) = 0$ unless $\# \mathcal{T} \leq \# \mathcal{S} \cdot (q - 1) + 2$.

**Proof.** Let $\mathcal{T}$ be kabi over $\mathcal{S}$. Every vertex of $\mathcal{S}$ is connected to at most $q$ number of points of $\mathcal{T}$. Since $\mathcal{S}$ is connected, it has at least $\# \mathcal{S} - 1$ number of edges. Hence, $\# \mathcal{T} - \# \mathcal{S} \leq \# \{\text{edges connecting } \mathcal{S} \text{ and } \mathcal{T}\setminus \mathcal{S}\} \leq q \cdot \# \mathcal{S} - 2 \cdot (\# \mathcal{S} - 1)$. This implies the Assertion. \(\square\)
Remark. The above boundedness implies that $K$ induces a continuous map between the two differently completed modules of $L_{\mathbb{A},\text{finite}}$ (cf. §8.4).

§8. Lie-like elements $L_{\mathbb{A}}$

Under the assumption $\mathbb{Q} \subset \mathbb{A}$, we introduce two basis systems $\{M(T)\}_{T \in \text{Conf}_0}$ and $\{\varphi(S)\}_{S \in \text{Conf}_0}$ for the module of Lie-like elements $L_{\mathbb{A},\text{finite}}$, where the base change between them is given by the kabi-coefficients. The basis $\{\varphi(S)\}_{S \in \text{Conf}_0}$ is compatible with the adic topology and gives a topological basis of $L_{\mathbb{A}}$.

8.1 The splitting map $\partial$

First, we introduce a useful but somewhat technical map $\partial$. One reason for its usefulness can be seen from the formula (9.3.6). For $S \in \text{Conf}_0$, let us define an $\mathbb{A}$-linear map $\partial_S : \mathbb{A}[\text{Conf}] \to \mathbb{A}$ by associating to a series $f$ its coefficient at $S$, i.e. $\partial_S f := f_S \in \mathbb{A}$ for $f$ given by (3.2.4). By the use of this, we define

\[
\begin{align*}
\partial : \mathbb{A}[\text{Conf}] &\to \prod_{S \in \text{Conf}_0} \mathbb{A} \cdot e_S, \\
 f &\mapsto \sum_{S \in \text{Conf}_0} (\partial_S f) \cdot e_S
\end{align*}
\]

(8.1.1)

Here, the right hand side is an abstract direct product module of rank one modules $\mathbb{A} \cdot e_S$ with the base $e_S$ for $S \in \text{Conf}_0$. Let us verify that the map is well-defined. First, define the map $\partial$ from the polynomial ring $\mathbb{A} \cdot \text{Conf}$ to $\bigoplus_{S \in \text{Conf}_0} \mathbb{A} \cdot e_S$. Since $\partial(J_n) \subset \bigoplus_{S \in \text{Conf}_0} \mathbb{A} \cdot e_S$, the map is continuous with respect to the adic topology (3.2) on the LHS and the direct product topology on the RHS. Then, $\partial$ (8.1.1) is obtained by completing this polynomial map.

We note that the restriction of the map $\partial$ (8.1.1) induces a map

\[
\partial : \mathbb{A}[\text{Conf}]_{\text{finite}} \to \bigoplus_{S \in \text{Conf}} \mathbb{A} \cdot e_S,
\]

even though the domain of this map is not a polynomial ring but the ring of elements of finite type (recall the definition in §8.3).

8.2 Bases $\{\varphi(S)\}_{S \in \text{Conf}_0}$ of $L_{\mathbb{A},\text{finite}}$ and $L_{\mathbb{A}}$

Lemma. Let $\mathbb{A}$ be a commutative algebra containing $\mathbb{Q}$. Then,

i) The system $(\mathcal{M}(T))_{T \in \text{Conf}_0}$ give a $\mathbb{A}$-free basis for $L_{\mathbb{A},\text{finite}}$.

(8.2.1) $L_{\mathbb{A},\text{finite}} \simeq \bigoplus_{S \in \text{Conf}_0} \mathbb{A} \cdot \mathcal{M}(S)$.

ii) The map $\partial$ (8.1.1) induces a bijection of $\mathbb{A}$-modules:

(8.2.2) $\partial|_{L_{\mathbb{A},\text{finite}}} : L_{\mathbb{A},\text{finite}} \simeq \bigoplus_{S \in \text{Conf}_0} \mathbb{A} \cdot e_S$
Put $\varphi(S) := \partial|_{\mathcal{L}_{\mathbb{A}, \text{finite}}}^{-1}(e_S)$ for $S \in \text{Conf}_0$ so that $\{\varphi(S)\}_{S \in \text{Conf}_0}$ form another $\mathbb{A}$-free basis of $\mathcal{L}_{\mathbb{A}, \text{finite}}$.

iii) The two basis systems $\{\mathcal{M}(S)\}_{S \in \text{Conf}_0}$ and $\{\varphi(S)\}_{S \in \text{Conf}_0}$ for $\mathcal{L}_{\mathbb{A}, \text{finite}}$ are related by the following formula.

$$\mathcal{M}(T) = \sum_{S \in \text{Conf}_0} \varphi(S) \cdot A(S, T)$$ (8.2.3)

$$\varphi(S) = \sum_{T \in \text{Conf}_0} \mathcal{M}(T) \cdot (-1)^{#T - #S} K(T, S).$$ (8.2.4)

iv) $\mathcal{L}_{\mathbb{A}, \text{finite}}$ is dense in $\mathcal{L}_{\mathbb{A}}$ with respect to the adic topology on the configuration algebra (cf. (3.2)).

v) The map $\partial$ induces an isomorphism of topological $\mathbb{A}$-modules:

$$\mathcal{L}_{\mathbb{A}} \cong \prod_{S \in \text{Conf}_0} \mathbb{A} \cdot e_s.$$ (8.2.5)

This means that any $\mathcal{M} \in \mathcal{L}_{\mathbb{A}}$ is expressed uniquely as an infinite sum

$$\mathcal{M} = \sum_{S \in \text{Conf}_0} \varphi(S) \cdot a_S$$ (8.2.6)

for $a_S \in \mathbb{A}$ ($S \in \text{Conf}_0$). That is, $\{\varphi(S)\}_{S \in \text{Conf}_0}$ is a topological basis of $\mathcal{L}_{\mathbb{A}}$. We shall, sometimes, call $a_S$ the coefficient of $\mathcal{M}$ at $S \in \text{Conf}_0$.

**Proof.** That $\mathcal{M}(T) \in \mathcal{L}_{\mathbb{A}, \text{finite}}$ for $T \in \text{Conf}$ is shown in (6.2) Lemma. In the following a), b) and c), we prove i), ii) and iii) simultaneously.

a) The restriction of the map $\partial$ on $\mathcal{L}_{\mathbb{A}}$ is injective.

**Proof.** If $\mathcal{M} = \sum_{S \in \text{Conf}} S \cdot M_S \in \mathbb{A} \llbracket \text{Conf} \rrbracket_+$ is Lie-like (6.3), then one has

$$\sum_{S \in \text{Conf}} \left( S_{S_1, \ldots, S_m} \right) M_S = 0$$ (8.2.7)

for any $S_1, \ldots, S_m \neq \emptyset$ and $m \geq 2$ (the proof is the same as that for (6.2.2)). We have to prove that $\partial \mathcal{M} = 0$ implies $M_S = 0$ for all $S \in \text{Conf}$. This will be done by induction on $n(S) = \#\{\text{connected components of } S\}$ as follows. The case $n(S) = 1$ follows from the assumption $\partial \mathcal{M} = 0$. Let $n(S) > 1$ and $S = S_1^{k_1} \sqcup \cdots \sqcup S_l^{k_l}$ be an irreducible decomposition of $S$ (so $S_i \in \text{Conf}_0$ ($i = 1, \ldots, l$) are pairwise distinct). Apply [8.2.7] for $m = k_1 + \cdots + k_l = n(S)$ and take $S_1, \ldots, S_1$ ($k_1$ times), $\ldots, S_i, \ldots, S_l$ ($k_l$ times) for $S_1, \ldots, S_m$.

$$** \quad k_1! \cdots k_l! M_S + \sum_{T \in \text{Conf}} \left( T_{S_1, \ldots, S_m} \right) M_T = 0$$
Limits in the Configuration Algebra

By the induction hypothesis, the second term in \(\ast\ast\) is 0, and hence \(M_S = 0\).

b) For \(T \in \text{Conf}\), one has the formula:

\[
\partial(M(T)) = \sum_{S \in \text{Conf}_0} e_S \cdot A(S, T).
\]

(Proof. Recall that \(M(T) = \log(A(T))\) and the coefficients of \(M(T)\) and \(A(T)\) at a connected \(S \in \text{Conf}_0\) coincide ((3.6.7) and (6.1.6)). That is, \(\partial(M(T)) = \partial(A(T))\). By definition, \(\partial(A(T))\) is the right hand side of (8.2.8). \(\square\)

c) The map (8.2.2) is surjective, and hence, is bijective.

Proof. It was shown in §7 that the infinite matrix \((A(S, T))_{S, T \in \text{Conf}_0}\) is invertible as a unipotent matrix (7.1). Then (8.2.8) implies surjectivity.

Using again (8.2.8), we have that the system \(\{M(T)\}_{T \in \text{Conf}_0}\) is \(A\)-linearly independent and spans \(L_{\mathbb{A}, \text{finite}}\), i.e. i) holds. The formula (8.2.8) can be rewritten as (8.2.3). Then (8.2.4) follows from (8.2.3) and (7.4.2) \(\square\).

Proof of iv) and v) is done in the following a), b) and c).

a) \(L_{\mathbb{A}}\) is closed in \(\mathbb{A}[\text{Conf}]\) with respect to the adic topology, since the co-product \(\Phi_m\) is continuous (4.1 Assertion). Thus: \((L_{\mathbb{A}, \text{finite}})^\text{closure} \subset L_{\mathbb{A}}\).

b) The map (8.2.2) is homeomorphic with respect to the topologies: the induced adic topology on the LHS and the restriction of the direct product topology on the RHS. (To show this, it is enough to show the bijection:

\[
\partial : (L_{\mathbb{A}, \text{finite}}) \cap I_n \simeq \bigoplus_{S \in \text{Conf}_0 \#S \geq n} \mathbb{A} \cdot e_S,
\]

since the sets on the RHS for \(n \in \mathbb{Z}_{\geq 0}\) can be chosen as a system of fundamental neighborhoods for the direct product topology on \(\bigoplus_{S \in \text{Conf}_0} \mathbb{A} \cdot e_S\).

Proof of (8.2.9). Due to the definition of the ideal \(I_n\) (3.2.1), the \(\partial\)-image of the left hand side is contained in the right hand side of (8.2.9). Thus, one has only to show surjectivity. For \(S \in \text{Conf}_0\), let \(\varphi(S)\) be the base of \(L_{\mathbb{A}, \text{finite}}\) such that \(\partial(\varphi(S)) = e_S\) as introduced in ii). It is enough to show that if \(#S \geq n\) and \(S \in \text{Conf}_0\), then \(\varphi(S)\) belongs to \(I_n\). Expand \(\varphi(S) = \sum U \cdot \varphi_U\). We show that \(\varphi_U \neq 0\) implies that \(U\) is contained in the semi-group generated by \(\langle S \rangle\) such that \(#U \geq n\). More precisely, we show \((U_1, \ldots, U_m) \neq 0\), where \(U = U_1 \sqcup \cdots \sqcup U_m\) is an irreducible decomposition of \(U\) (cf. (2.5) i)). The proof is achieved by induction on \(m = n(U)\). For the case \(n(U) = 1\), \(\varphi_U \neq 0\) if and only if \(U = S\) by the definition of \(\varphi(S)\), and hence this is trivial. If \(n(U) > 1\), then apply (8.2.7) similarly to \(\ast\ast\) for the irreducible decomposition of \(U\). We get:

\[
\ast\ast\ast\]

\[
k_1! \cdots k_l! \varphi_U + \sum_{T \in \text{Conf}} T \in n(U) \left( U_1, \ldots, U_m \right) \varphi_T = 0
\]
The fact that $\varphi \neq 0$ implies $\varphi_T \cdot (U, \ldots, U_m) \neq 0$ for some $T$. Since $\varphi_T \neq 0$ with $n(T) < n(U)$, we apply the induction hypothesis to $T$, i.e. $(T_1, \ldots, T_p) \neq 0$ for an irreducible decomposition $T = T_1 \sqcup \ldots \sqcup T_p$. Since $(U_1, \ldots, U_m) \neq 0$, by composing the maps $U \to T \to S$, we conclude $(U, \ldots, U_m) \neq 0$. In particular, $U_i \in S$ and $\# U = \sum \# U_i \geq \# T \geq \# S$. This completes the proof of b). $\square$

c) By completing the map (8.2.2), one sees that the composition of the two injective maps $(L_A, \text{finite}) \cup (L_A, \text{finite}) \to \lim_{\longrightarrow} \prod_{S \in \text{Conf}_0} A \cdot e_s$ is bijective. This shows that all the maps are bijective. Hence, $L_A, \text{finite}$ is dense in $L_A$ and (8.2.5) holds. The formula (8.2.6) is another expression of (8.2.5).

This completes the proof of the Lemma.

Remark. 1. It was shown in the above proof that for $S \in \text{Conf}_0$

$$\varphi(S) \in \mathbb{Z}[\langle S \rangle] \cap J_{\# S}. \tag{8.2.10}$$

In particular, $\varphi(U, S) = \delta(U, S)$ for $U \in \text{Conf}_0$.

2. It was shown that the map $\partial|_{L_A, \text{finite}}$ (8.2.2) is a homeomorphism. But one should note that (8.2.1) is not a homeomorphism.

3. In general, an element of $L_A$ cannot be expressed by an infinite sum of $M(T)$ ($T \in \text{Conf}_0$) (cf. (9.4)).

4. The set of Lie-like elements of the localization $A[\text{Conf}], \text{finite}$ (cf. (4.6) Remark 4.) is equal to $L_A, \text{finite}_0$. This is insufficient for our later application in §10, so we employed the other localization (3.2.2).

8.3 An explicit formula for $\varphi(S)$

Let us expand $\varphi(S)$ for $S \in \text{Conf}_0$ in the series:

$$\varphi(S) = \sum_{U \in \text{Conf}} U \cdot \varphi(U, S) \tag{8.3.1}$$

for $\varphi(U, S) \in \mathbb{Q}$. The formula (8.2.3) can be rewritten as a matrix relation

$$M(U, T) = \sum_{S \in \text{Conf}_0} \varphi(U, S) \cdot A(S, T). \tag{8.3.2}$$

We remark that (8.2.3) and (8.3.2) are valid not only for $T \in \text{Conf}_0$ but for all $T \in \text{Conf}$, since both sides are additive with respect to $T$.

Formula. An explicit formula for the coefficients $\varphi(U, S)$.

$$\sum_{U=U_1^{k_1} \cdots U_m^{k_m}, V \in \text{Conf}, W \in \text{Conf}_0} \frac{(|\langle k \rangle - 1|)!(-1)^{|W|-1+|W|+|S|}}{k_1! \cdots k_m!} V_{k_1 \cdots k_m} A(V, W) K(W, S). \tag{8.3.3}$$
Here the summation index runs over all decompositions $U = U_1^{k_1} \cdots U_l^{k_l}$ of $U$ in the same manner explained at (3.6.6), where $|k| = k_1 + \cdots k_l$.

Proof. By use of (6.1.5), rewrite the left hand side of (8.2.3) into a polynomial of $A(U_i, T)$. Then apply the product expansion formula (5.3.1) to each monomial so that the left hand side is expressed linearly by $A(S, T)$'s. Using the invertibility of $\{A(S, T)\}_{S,T \in \text{Conf}}$ (12.4.2), one deduces (8.3.3). □

Remark. As an application of (8.3.3), we can explicitly determine the coefficients $\{M_U\}_{U \in \text{Conf}}$ of any Lie-like element $M = \sum_{U \in \text{Conf}} U \cdot M_U$ from the subsystem $\{M_S\}_{S \in \text{Conf}_0}$ by the relation $M_U = \sum_{S \in \text{Conf}_0} \varphi(U, S) \cdot M_S$. Here, the summation index $S$ runs only over the finite set with $\#S \leq \#U$.

8.4 Lie-like elements $\mathcal{L}_{h, \infty}$ at infinity

We introduce the space $\mathcal{L}_{h, \infty}$ of Lie-like elements at infinity for a use after §10. Recall that the kabi coefficients relate the two basis systems of $\mathcal{L}_{h, \text{finite}}$: $\{\varphi(S)\}_{S \in \text{Conf}_0}$ and $\{M(T)\}_{T \in \text{Conf}_0}$ (cf.(8.2) lemma). The map:

$$K : \sum_{S \in \text{Conf}_0} \varphi(S) \cdot a_S \mapsto \sum_{T \in \text{Conf}_0} M(T) \sum_{S \in \text{Conf}_0} (-1)^{\#T - \#S} K(T, S) \cdot a_S$$

is the identity homomorphism between the same modules. We define topologies on the modules of both sides: the fundamental system of neighborhoods of 0 are the linear subspaces spanned by the all bases except for finite ones. Actually, the topology on the LHS coincides with the adic topology, which we have been studying (8.2 Lemma). The map $K$ is continuous with respect to the topologies, since for any base $M(T)$, there are only a finite number of bases $\varphi(S)$ whose image $K(\varphi(S))$ contains the term $M(T)$, namely $K(T, S) \neq 0$ only for such $S$ satisfying $\#T \geq \frac{1}{q-1}(\#S - 2)$, (7.5) Assertion. Let us denote by $\overline{K}$ the map between the completed modules and call it the kabi map.

$$\overline{K} : \mathcal{L}_h \longrightarrow \prod_{T \in \text{Conf}_0} \mathbb{A} \cdot M(T).$$

We consider the set of Lie-like elements which are annihilated by the kabi map:

$$\mathcal{L}_{h, \infty} := \ker(\overline{K}),$$

and call it the space of Lie-like elements at infinity. In fact, $\mathcal{L}_{h, \infty}$ does not contain a non-trivial finite type element, i.e. $\mathcal{L}_{h, \text{finite}} \cap \mathcal{L}_{h, \infty} = \{0\}$. However,
the direct sum $\mathcal{L}_A,\text{finite} \oplus \mathcal{L}_A,\infty$ is a small submodule of $\mathcal{L}_A$, and one looks for a submodule, say $\mathcal{L}'$, of $\mathcal{L}_A$ containing $\mathcal{L}_A,\text{finite}$, with a splitting $\mathcal{L}_A = \mathcal{L}' \oplus \mathcal{L}_A,\infty$. However, there is some difficulty in finding such $\mathcal{L}'$ for general $A$: an infinite sum $\sum_{T \in \text{Conf}_0} a_T \mathcal{M}(T) \in \text{Im}(K)$ never converges in $\mathcal{L}' (\simeq \text{Im}(K))$ with respect to the adic topology. We shall come back to this problem in (10.2) for the case $A = \mathbb{R}$, where the classical topology plays the crucial role.

§9. Group-like elements $\mathfrak{G}_A$

We determine the groups $\mathfrak{G}_A$ and $\mathfrak{G}_A,\text{finite}$ of group-like elements in $A[\text{Conf}]$ and $A[\text{Conf}],\text{finite}$, respectively, if $A$ is $\mathbb{Z}$-torsion free. In particular, if $A = \mathbb{Z}$, the group $\mathfrak{G}_{\mathbb{Z},\text{finite}}$ is, by the correspondence $A(S) \leftrightarrow S$, isomorphic to $\langle \text{Conf} \rangle =$the abelian group associated to the semi-group $\text{Conf}$, and it forms a "lattice in the continuous group" $\mathfrak{G}_\mathbb{R}$. Then, we introduce the set $\text{EDP}$ of equal division points inside the positive cone in $\mathfrak{G}_\mathbb{R}$ spanned by the basis $\{\mathcal{M}(S)\}$.

9.1 $\mathfrak{G}_{A,\text{finite}}$ and $\mathfrak{G}_A$ for the case $\mathbb{Q} \subset A$

We start with a general fact: Assume $\mathbb{Q} \subset A$. Then one has isomorphisms:

\[(9.1.1) \quad \exp : \mathcal{L}_A \simeq \mathfrak{G}_A, \quad \exp : \mathcal{L}_A,\text{finite} \simeq \mathfrak{G}_A,\text{finite}.\]

Proof. Since $\text{aug}(g) = 1$, $\log(g)$ \((3.6.2)\) is well defined for $\mathbb{Q} \subset A$. That $g$ is group-like \((5.4.1)\) implies that $\log(g)$ is Lie-like and belongs to $\mathcal{L}_A$ (cf. proof of \((6.2)\) Lemma). Then $g$ is of finite type, if and only if $\log(g)$ is so (cf. \((3.6)\)). Thus \((9.1.1)\) is shown. The homeomorphism follows from that of $\exp$ \((3.6)\).

9.2 Generators of $\mathfrak{G}_{A,\text{finite}}$ and $\mathfrak{G}_A$ for a $\mathbb{Z}$-torsion free $A$.

Lemma. Let $A$ be a commutative $\mathbb{Z}$-torsion-free algebra with unit.

i) Any element $g$ of $\mathfrak{G}_{A,\text{finite}}$ is uniquely expressed as

\[(9.2.1) \quad g = \prod_{i \in I} A(S_i)^{c_i}\]

for $S_i \in \text{Conf}_0$ and $c_i \in A$ ($i \in I$) with $\#I < \infty$. That is, one has an isomorphism:

\[(9.2.2) \quad \langle \text{Conf} \rangle \otimes_{\mathbb{Z}} A \simeq \mathfrak{G}_{A,\text{finite}}, \quad S \leftrightarrow A(S),\]

where $\langle \text{Conf} \rangle$ is the group associated to the semi-group $\text{Conf}$.

ii) $\mathfrak{G}_{A,\text{finite}}$ is dense in $\mathfrak{G}_A$ with respect to the adic topology.
iii) We have the natural inclusion:

\[(9.2.3) \quad \{\exp(\varphi(S)) \mid S \in \text{Conf}_0\} \subset \mathfrak{G}_{\mathbb{Z}, \text{finite}}\]

The set \(\{\exp(\varphi(S))\}_{S \in \text{Conf}_0}\) is a topological free generating system of \(\mathfrak{G}_\mathbb{A}\). This means that any element \(g\) of \(\mathfrak{G}_\mathbb{A}\) is uniquely expressed as an infinite product:

\[(9.2.4) \quad \prod_{S \in \text{Conf}_0} \exp(\varphi(S) \cdot a_S) := \lim_{n \to \infty} \left( \prod_{S \in \text{Conf}_0} \exp(\varphi(S) \cdot a_S) \right)\]

for some \(a_S \in \mathbb{A}\) \((S \in \text{Conf}_0)\).

**Proof.** If \(\mathbb{Q} \subset \mathbb{A}\), then due to the isomorphisms (8.2.4), (8.2.10) and the integrality of \(k_{ab}\) \((8.2.3)\), we have

\[\exp(\varphi(S)) = \prod_{T \in \text{Conf}_0} \mathcal{A}(T)^{-(1)^{#T} \cdot T} \cdot K(T,S) \in \mathfrak{G}_{\mathbb{Z}, \text{finite}} \cap \{1 + J\}_{#T = \infty},\]

where we note \(\mathcal{A}(T) \in \mathfrak{G}_{\mathbb{Z}, \text{finite}}\) (c.f. (8.2.6) and (8.2.4)).

Assume \(\mathbb{Q} \nsubseteq \mathbb{A}\) and let \(\tilde{\mathbb{A}}\) be the localization of \(\mathbb{A}\) with respect to \(\mathbb{Z} \setminus \{0\}\). Since \(\mathbb{A}\) is torsion free, one has an inclusion \(\mathbb{A} \subset \tilde{\mathbb{A}}\), which induces inclusions \(\mathfrak{G}_\mathbb{A} \subset \mathfrak{G}_{\tilde{\mathbb{A}}}\) and \(\mathfrak{G}_{\mathbb{A}, \text{finite}} \subset \mathfrak{G}_{\tilde{\mathbb{A}}, \text{finite}}\), and the Lemma is true for \(\mathfrak{G}_{\tilde{\mathbb{A}}, \text{finite}}\) and \(\mathfrak{G}_{\tilde{\mathbb{A}}}\).

i) Let us express an element \(g \in \mathfrak{G}_{\mathbb{A}, \text{finite}}\) as \(\prod_{i \in I} \mathcal{A}(S_i)^{c_i}\), where \(c_i \in \tilde{\mathbb{A}}\) for \(i \in I\) and \(#I < \infty\). We need to show that \(c_i \in \tilde{\mathbb{A}}\) for \(i \in I\). Suppose not. Put \(I_1 := \{i \in I : c_i \notin \tilde{\mathbb{A}}\}\) and let \(S_1\) be a maximal element of \(\{S_i : i \in I\}\) with respect to the partial ordering \(\leq\). Put \(g_1 := \prod_{i \in I \setminus I_1} \mathcal{A}(S_i)^{c_i}\) and \(g_2 := \prod_{i \in I_1 \setminus I} \mathcal{A}(S_i)^{c_i}\). Then \(g_1 \mathcal{A}(S_1)^{c_1} = g \cdot g_2^{-1} \in \mathfrak{G}_{\mathbb{A}, \text{finite}}\). In the left hand side, \(g_1\) does not contain the term \(S_1\), whereas \(\mathcal{A}(S_1)^{c_1}\) contains the term \(c_1 S_1\). Hence, the left hand side contains the term \(c_1 S_1\).

ii) Let any \(g \in \mathfrak{G}_\mathbb{A}\) be given. For a fixed integer \(n \in \mathbb{Z}_{\geq 0}\), we calculate

\[\log(g) = \sum_{S \in \text{Conf}_0} \varphi(S) \cdot a_S \quad \text{for} \quad a_S \in \tilde{\mathbb{A}} \quad \text{(c.f. (8.2.6))}\]

\[= \sum_{T \in \text{Conf}_0} \mathcal{M}(T) \cdot c_{T,n} + R_n, \quad \text{where}\]

\[c_{T,n} : = \sum_{S \in \text{Conf}_0 \setminus \#S < n} (-1)^{#T - #S} K(T,S) \cdot a_S \in \tilde{\mathbb{A}}, \quad \text{(c.f. (8.2.4))}\]

\[R_n : = \sum_{S \in \text{Conf}_0 \setminus \#S \geq n} \varphi(S) \cdot a_S. \quad \text{**)**}\]

Here we notice that

\[c_{T,n} \neq 0 \implies #T < n, \quad \text{since} \quad K(T,S) \neq 0 \implies T \leq S \quad \text{(7.2.3)}.\]
\( R_n \in J_n \), since \( \#S \geq n \) implies \( \varphi(S) \in J_n \) \( (8.2.10) \).

Therefore
\[
g = \sum_{T \in \text{Conf}_0} A(T)^{ct_{T,n}} \cdot \exp(R_n) = 0
\]
mod \( J_n \).

Let us show that \( ct_{T,n} \in A \) for all \( T \in \text{Conf}_0 \). Suppose not, and let \( T_1 \) be a maximal element of \( \{ T \in \text{Conf}_0 : \#T < n \text{ and } ct_{T,n} \notin A \} \). Then similar to the proof of i), the coefficient of \( g \) at \( T_1 = ct_{T_1,n} \mod A \neq 0 \mod A \). This is a contradiction. Therefore, \( ct_{T,n} \in A \) for all \( T \) and hence, \( g \in \mathfrak{S}_{A,\text{finite}} \) mod \( J_n \).

iii) Applying \( (7.4.2) \) to the relation \( \ast \) in the proof of ii), one gets
\[
a_S = \sum_{T \in \text{Conf}_0} A(S,T) \cdot ct_{T,n}
\]
for \( \#S < n \). Here the right hand side belongs to \( A \) due to the proof ii). On the other hand, the left hand side \( (= a_S) \) does not depend on \( n \). Hence, by moving \( n \in \mathbb{Z}_{\geq 0} \), one has proven that \( a_S \in A \) for all \( S \in \text{Conf}_0 \).

\section*{9.3 Additive characters on \( \mathfrak{S}_A \)}

**Definition.** An additive character on \( \mathfrak{S}_A \) is an additive homomorphism
\[
\chi : \mathfrak{S}_A \rightarrow A,
\]
which is continuous with respect to the adic topology on \( \mathfrak{S}_A \) such that
\[
\chi(g^a) = \chi(g) \cdot a
\]
for all \( g \in \mathfrak{S}_A \) and \( a \in A \). The continuity of \( \chi \) \( (9.3.1) \) is equivalent to the statement that there exists \( n \geq 0 \) such that \( \chi(\exp(\varphi(S))) = \chi(1) = 0 \) for \( S \in J_n \cap \text{Conf}_0 \). Hence it is equivalent to \( \#\{ S \in \text{Conf}_0 : \chi(\exp(\varphi(S))) \neq 0 \} < \infty \).

The set of all additive characters will be denoted by
\[
\text{Hom}_A(\mathfrak{S}_A,A).
\]

**Assertion.** 1. For any fixed \( U \in \text{Conf}_0 \), the correspondence
\[
\chi_U : A(S) \in \mathfrak{S}_{Z,\text{finite}} \mapsto A(U,S) \in \mathbb{Z}
\]
extends uniquely to an additive \( A \)-character on \( \mathfrak{S}_A \), denoted by \( \chi_U \). Then
\[
\chi_U(\exp(\varphi(S))) = \delta(U,S) \quad \text{for } U,S \in \text{Conf}_0.
\]
2. There is a natural isomorphism

\[ \text{Hom}_A(\mathfrak{G}_A, A) \to \bigotimes_{U \in \text{Conf}_0} A \cdot \mathcal{X}_U, \]

\[ X \mapsto \sum_{U \in \text{Conf}_0} X_U(\exp(\varphi(S))) \cdot \mathcal{X}_U. \]

3. If \( \mathbb{Q} \subset A \), then for any \( \mathcal{M} \in \mathcal{L}_A \) and \( U \in \text{Conf}_0 \) one has

\[ \mathcal{X}_U(\exp(\mathcal{M})) = \partial U \mathcal{M}. \]

**Proof.** 1. First we note that \( A(U, S) \) for fixed \( U \in \text{Conf}_0 \) is additive in \( S \), so that \( \mathcal{X}_U \) naturally extends to an additive homomorphism on \( G \). For continuity (i.e. the finiteness of \( S \) with \( \mathcal{X}_U(\exp(\varphi(S))) \neq 0 \)), it is enough to show (9.3.4). Recalling (8.2.4) and (7.4.2), this proceeds as:

\[ \mathcal{X}_U(\exp(\mathcal{M})) = \mathcal{X}_U(\exp(\sum_{T \in \text{Conf}_0} \mathcal{M}(T)(-1)^{#T - #S} K(T, S))) = \sum_{T \in \text{Conf}_0} \mathcal{X}_U(\mathcal{X}_U(\exp(\mathcal{M}(T))) \cdot (-1)^{#T - #S} K(T, S)) = \sum_{T \in \text{Conf}_0} \mathcal{X}_U(\sum_{T \in \text{Conf}_0} A(U, T) \cdot (-1)^{#T - #S} K(T, S) = \delta(U, S). \]

2. The continuity of \( \mathcal{I} \) implies the sum in the target space is finite.

3. Both sides of (9.3.6) take the same values for the basis \( (\varphi(S))_{S \in \text{Conf}_0} \).

**9.4 Equal division points of \( \mathfrak{G}_{\mathbb{Z}, \text{finite}} \)**

Recalling \( \langle \text{Conf} \rangle \simeq \mathfrak{G}_{\mathbb{Z}, \text{finite}} \), we regard \( \langle \text{Conf} \rangle \) as a “lattice” in \( \mathfrak{G}_{\mathbb{R}, \text{finite}} \). In the positive rational cone \( \mathfrak{G}_{\mathbb{Q}, \text{finite}} \cap (\prod_{S \in \text{Conf}_0} \mathcal{A}(S)^{\geq 0}) \), we consider a particular point, which we call the **equal division point** for \( S \in \text{Conf} \):

\[ \mathcal{A}(S)^{1/\sharp(S)}. \]

Here, the exponent \( 1/\sharp(S) \) is chosen so that we get the normalization:

\[ \mathcal{X}_{pt}(\mathcal{A}(S)^{1/\sharp(S)}) = 1. \]

The set of all equal division points is denoted by

\[ \text{EDP} := \{ \mathcal{A}(S)^{1/\sharp(S)} | S \in \text{Conf} \}. \]

The formulation of (9.4.1) is inspired from the free energy of Helmholtz in statistical mechanics. Instead of treating equal division points in the form (9.4.1) in \( \mathfrak{G}_{\mathbb{R}} \), we shall treat their logarithms in \( \mathcal{L}_{\mathbb{R}} \) in the next paragraphs.
9.5 A digression to $\mathcal{L}_A$ with $\mathbb{Q} \not\subset A$

We have determined the generators of $\mathfrak{G}_A,_{\text{finite}}$ and $\mathfrak{G}_A$ without assuming $\mathbb{Q} \subset A$ but assuming only $\mathbb{Z}$-torsion freeness of $A$. The following Assertion seems to suggest that the Lie-like elements behave differently to the group-like elements. However we do not pursue this subject any further in the present paper.

**Assertion.** Let $A$ be a commutative algebra with unit. If there exists a prime number $p$ such that $A$ is $p$-torsion free and $1/p \notin A$, then $\mathcal{L}_A$ is divisible by $p$ (i.e. $\mathcal{L}_A = p\mathcal{L}_A$). In particular, if $A$ is noetherian, $\mathcal{L}_A = \{0\}$.

**A sketch of the proof.** Consider an element $M = \sum_{U \in \text{Conf}} U \cdot M_U \in \mathcal{L}_A$. As an element of $\mathcal{L}_A$, it can be expressed as $\sum_{S \in \text{Conf}_0} \varphi(S) \cdot a_S$ where $a_S = \partial_S M = M_S \in A$ for $S \in \text{Conf}_0$. Recall the expression (8.3.3) for $\varphi(U, S)$ ($U \in \text{Conf}$) and the remark following it. We see that $M_U$ is expressed as:

$$\sum_{U = \{U_1, U_2, \ldots, U_m\}, V \in \text{Conf}, W, S \in \text{Conf}_0} \frac{(-1)^{|V|-1+|W|+|S|}(|k| - 1)!}{k_1! \cdots k_m!} \left(\frac{|pt\varepsilon|}{V_{k_1}} U_{k_1} \cdots U_{k_m} W_{k_1} \cdots W_{k_m}\right) A(V, W) K(W, S) a_S.$$

Apply this formula for $U = T^p$ for a fixed $T \in \text{Conf}_0$. The summation index set is $\{(k_1, k_2, \ldots) \in (\mathbb{Z}_{\geq 0})^{\geq 1} \mid p = \sum_{i \geq 1} i \cdot k_i\}$, as explained in 3.6

**Example.** Except for the case $k_1 = p$ and $k_i = 0$ ($i > 1$), the denominator $k_1! \cdots k_m!$ is a product of prime numbers smaller than $p$. The coefficient

$$\left(\frac{U_{k_1} \cdots U_{k_m}}{V_{k_1}} \right)$$

for this case (i.e. $k_1 = p, k_i = 0$ ($i > 1$) and for $V = [V]$ is equal to the cardinality of the set $\{(U_1, \ldots, U_p) \mid U_i$ is a subgraph of $V$ such that $[U_i] = T$ and $\cup_{i=1}^p U_i = V\}$. Since the cyclic permutation of $U_1, \ldots, U_p$ acts on the set, and the action has no fixed points except for $V = T$, we see that the covering coefficient is divisible by $p$ except for the case $V = T \in \text{Conf}_0$. In that case $\sum_{W \in \text{Conf}_0} (-1)^{|W|+|S|} A(T, W) K(W, S) = \delta(T, S)$. Therefore $\frac{(-1)^p}{p} a_T \equiv 0 \mod \mathcal{A}_{\text{loc}}$ where $\mathcal{A}_{\text{loc}}$ is the localization of the algebra $A$ with respect to the prime numbers smaller than $p$. Hence $a_T \in p\mathcal{A}_{\text{loc}} \cap A = pA$.

$\Box$

\section{10. Accumulation set of logarithmic equal division points}

We consider the space of Lie-like elements $\mathcal{L}_\mathbb{R}$ over the real number field $\mathbb{R}$ which is equipped with the classical topology. The set in $\mathcal{L}_\mathbb{R}$ of accumulation
points of the logarithm of EDP \((9.4)\), denoted by \(\Omega := \log(\text{EDP})\), becomes a compact convex set. We decompose \(\Omega = \log(\text{EDP})\) into a join of the finite (absolutely convergent) part \(\Omega_{\text{abs}} := \log(\text{EDP})_{\text{abs}}\) and the infinite part \(\Omega_{\infty} := \log(\text{EDP})_{\infty}\).

**10.1 The classical topology on \(L_{\mathbb{R}}\)**

We equip the \(\mathbb{R}\)-vector space

\[
L_{\mathbb{R}} = \lim_{\leftarrow} \frac{L_{\mathbb{R}}/J_n \cap L_{\mathbb{R}}}{L_{\mathbb{R}}/J_n \cap L_{\mathbb{R}}}
\]

with the classical topology defined by the projective limit of the classical topology on the finite quotient \(\mathbb{R}\)-vector spaces. Since the quotient spaces are

\[
L_{\mathbb{R}}/J_n \cap L_{\mathbb{R}} \cong \bigoplus_{S \in \text{Conf}_0} R \cdot \varphi(S) \cong L_{\mathbb{R}, \text{finite}}/J_n \cap L_{\mathbb{R}, \text{finite}},
\]

we see that 1) \(L_{\mathbb{R}}\) is homeomorphic to the direct product \(\prod_{S \in \text{Conf}_0} R \cdot \varphi(S)\) (recall \((8.2.5)\)), and 2) \(L_{\mathbb{R}, \text{finite}} \cong \bigoplus_{S \in \text{Conf}_0} R \cdot \varphi(S)\) is dense in \(L_{\mathbb{R}}\) with respect to the classical topology. That is, the classical topology on \(L_{\mathbb{R}}\) is the topology of the coefficient-wise convergence with respect to the basis \(\{\varphi(S)\}_{S \in \text{Conf}_0}\). It is weaker than the adic topology.

Similarly, we equip \(\mathbb{R}[\text{Conf}]\) with the classical topology defined by

\[
\mathbb{R}[\text{Conf}] = \lim_{\leftarrow} \frac{\mathbb{R} \cdot \text{Conf}/J_n}{\prod_{S \in \text{Conf}}} \mathbb{R} \cdot S.
\]

So, the classical topology on \(\mathbb{R}[\text{Conf}]\) is the same as the topology of coefficient-wise convergence with respect to the basis \(\{S\}_{S \in \text{Conf}}\). The next relation ii) between the two topologies \((10.1.1)\) and \((10.1.2)\) is a consequence of \((8.3.3)\).

**Assertion.** i) The product and coproduct on \(\mathbb{R}[\text{Conf}]\) are continuous with respect to the classical topology.

ii) The classical topology on \(L_{\mathbb{R}}\) is homeomorphic to the topology induced from that on \(\mathbb{R}[\text{Conf}]\).

iii) Let us equip \(\mathcal{G}_{\mathbb{R}}\) with the classical topology induced from that on \(\mathbb{R}[\text{Conf}]\). Then \(\exp : L_{\mathbb{R}} \to \mathcal{G}_{\mathbb{R}}\) is a homeomorphism.

**Proof.** i) The product and coproduct are continuous with respect to the adic topology (cf. \((6.2)\) and \((4.2)\)), which implies the statement.

ii) For a sequence in \(L_{\mathbb{R}}\), we need show the equivalence of convergence in \(L_{\mathbb{R}}\) and in \(\mathbb{R}[\text{Conf}]\). This is true due to \((8.3.3)\).

iii) The maps \(\exp\) and \(\log\) are bijective (cf. \((9.2)\) Assertion) and homeomorphic with respect to the adic topology, which implies the statement.
10.2 Absolutely convergent sum in $L_{\mathbb{R}}$

Recall the problem posed in 8.4: find a subspace of $L_{\mathbb{A}}$ containing $L_{\mathbb{A},finite}$ which is complementary to the subspace at infinity $L_{\mathbb{A},\infty}$ (8.4.2). In the present paragraph, we answer this problem for the case $\mathbb{A} = \mathbb{R}$ by introducing a sufficiently large submodule $L_{\mathbb{R},abs}$, which contains $L_{\mathbb{R},finite}$ but does not intersect with $L_{\mathbb{R},\infty}$ so that we obtain a splitting submodule $L_{\mathbb{R},abs} \oplus L_{\mathbb{R},\infty}$ of $L_{\mathbb{R}}$.

**Definition.** We say a formal sum $\sum_{T \in Conf_0} a_T \mathcal{M}(T) \in \prod_{T \in Conf_0} \mathbb{R} \cdot \mathcal{M}(T)$ is absolutely convergent if, for any $S \in Conf$, the sum $\sum_{T \in Conf_0} a_T \mathcal{M}(S, T)$ of its coefficients at $S$ is absolutely convergent, i.e. $\sum_{T \in Conf_0} |a_T| \mathcal{M}(S, T) < \infty$ for all $S \in Conf$. Then, any series $\sum_{i=1}^{\infty} a_T \mathcal{M}(T_i)$ defined by any linear ordering $T_1 < T_2 < \cdots$ of the index set $Conf_0$ converges in $L_{\mathbb{R}}$ to the same element with respect to the classical topology. We denote the limit by $\sum_{T \in Conf_0} a_T \mathcal{M}(T)$. Define the space of absolutely convergent elements:

\[(10.2.1) \quad L_{\mathbb{R},abs} := \{ \text{ all absolutely convergent sums } \sum_{T \in Conf_0} a_T \mathcal{M}(T) \} \]

By definition, $L_{\mathbb{R},abs}$ is an $\mathbb{R}$-linear subspace of $L_{\mathbb{R}}$ such that $L_{\mathbb{R},abs} \cap L_{\mathbb{R},\infty} = \{0\}$ and $L_{\mathbb{R},abs} \supset L_{\mathbb{R},finite}$. Hence, the restriction $K|L_{\mathbb{R},abs}$ of the kabi-map (8.4.1) is injective. We give a criterion for the absolute convergence, which guarantees that $L_{\mathbb{R},abs}$ will be large enough for our purpose (10.4.3).

**Assertion.** A formal sum $\sum_{T \in Conf_0} a_T \mathcal{M}(T)$ is absolutely convergent if and only if the sum $\sum_{T \in Conf_0} |a_T| \#(T)$ is convergent. The $L_{\mathbb{R},abs}$ is a Banach space with respect to the norm $| \sum_{T \in Conf_0} a_T \mathcal{M}(T) | := \sum_{T \in Conf_0} |a_T| \#(T)$.

**Proof.** The coefficient of $\mathcal{M}(T)$ at [one point graph] is equal to $\#(T)$. So absolute convergence implies the convergence of $\sum_{T \in Conf_0} |a_T| \#(T)$.

Conversely, under this assumption, let us show the absolute convergence of the sum $\sum_{T \in Conf_0} a_T \mathcal{M}(S, T)$ for any $S \in Conf$. We prove this by induction on $n(S) =$ the number of connected components of $S$. If $S$ is connected (i.e. $n(S) = 1$), then $A(S, T) = \mathcal{M}(S, T)$ and by the use of (5.2.1), we have $\sum_{T \in Conf_0} |a_T| \mathcal{M}(S, T) \leq (\sum_{T \in Conf_0} |a_T| \#(T) \frac{\#S}{\#Aut(S)})^{\#S^{-1}}$, which converges absolutely. If $S$ is not connected, decompose it into connected components as $S = \prod_{i=1}^{m} S_i$ and apply (6.2.2). Since $(S_1, \ldots, S_m) \neq 0$ implies either $n(S') < n(S)$ or $S' = S$, $\mathcal{M}(S, T)$ is expressed as a finite linear combination of $\mathcal{M}(S', T)$ for $n(S') < n(S)$ (independent of $T$). We are now done by the induction hypothesis.
10.3 Accumulating set $\Omega := \log(\text{EDP})$

Recall that an equal dividing point in $G \mathbb{Q}$ (9.4.1) is, by definition, an element of the form $A(S)^{1/\sharp(S)}$ for a $S \in \text{Conf}_+$. Let us consider the set in $L \mathbb{Q}$ of their logarithms (by use of the homeomorphism in 10.1 Assertion iii):

$$(10.3.1) \log(\text{EDP}) := \{M(T)/\sharp T \mid T \in \text{Conf}_+\}$$

and its closure $\Omega := \log(\text{EDP})$ in $L \mathbb{R}$ with respect to the classical topology. So, any element $\omega \in \Omega = \log(\text{EDP})$ has an expression:

$$(10.3.2) \omega := \lim_{n \to \infty} \frac{M(T_n)}{\# T_n}$$

for a sequence $\{T_n\}_{n \in \mathbb{Z}_>0}$ in $\text{Conf}_+$, where we denote by $\lim_{\text{cl}}$ the limit with respect to the classical topology. Recalling that the topology on $L \mathbb{R}$ is defined by the coefficient-wise convergence with respect to the basis $\{\psi(S)\}_{S \in \text{Conf}_0}$ and using (8.2.3), one has

$$\omega = \sum_{S \in \text{Conf}_0} \psi(S) \cdot a_S$$

where $a_S = \lim_{n \to \infty} A(S,T_n)/\# T_n$.

**Assertion.** 1. The set $\log(\text{EDP})$ is compact and convex.

2. Expand any element $\omega \in \log(\text{EDP})$ as $\sum_{S \in \text{Conf}_0} \psi(S) \cdot a_S$. Then

i) $0 \leq a_S \leq (q - 1)\sharp S - 1/\sharp \text{Aut}(S)$ for $S \in \text{Conf}_0$,

ii) $(q - 1)\sharp S - \sharp S' a_{S'} \geq a_S$ for $S' \leq S$. In particular, if $a_S \neq 0$ then $a_{S'} \neq 0$.

**Proof.** 1. Compactness: it is enough to show that the range of coefficients $a_S$ for $\omega \in \log(\text{EDP})$ is bounded for each $S \in \text{Conf}_0$. Recalling the expansion formula (8.2.3), this is equivalent to the statement that $\{A(S,T)/\# T \mid T \in \text{Conf}_0\}$ is bounded for any $S \in \text{Conf}_0$. Applying the inequality (5.2.2), we have

$$0 \leq A(S,T)/\# T \leq (q - 1)^{\sharp S - 1}/\# \text{Aut}(S),$$

which clearly gives a universal bound for $A(S,T)/\# T$ independent of $T$.

Convexity: since for any $T$, $T' \neq |\emptyset|$ and $r \in \mathbb{Q}$ with $0 < r < 1$, one can find positive integers $p$ and $q$ such that for $T'' := T^p \cdot T'^q$ one has

$$M(T'')/\# T'' = (p \cdot M(T) + q \cdot M(T'))/(p \cdot \# T + q \cdot \# T')$$

$$= r \cdot M(T)/\# T + (1 - r) \cdot M(T')/\# T'.$$

2. i) This is shown already in 1.

ii) If $S' \leq S$ and $S \in \text{Conf}_0$, then for any $T \in \text{Conf}$ one has an inequality

$$(q - 1)^{\sharp S - \sharp S'} A(S', T) \geq A(S, T).$$

This can be easily seen by fixing representatives of $S$ and $S'$ as in proof of (5.2.2). Therefore $(q - 1)^{\sharp S - \sharp S'} a_{S'} \geq a_S$. 

**Remark.** The condition (9.4.2) on EDP implies $a_{pt} = 1$ for any element $\omega \in \log(\text{EDP})$. In particular, this implies $0 \notin \Omega = \log(\text{EDP})$. 

10.4 Join decomposition $\Omega = \text{log}(\text{EDP})_{abs} \ast \text{log}(\text{EDP})_{\infty}$

We show that $\text{log}(\text{EDP})$ is embedded in $L_{R, \text{abs}} \oplus L_{R, \infty}$, and, accordingly, decompose $\text{log}(\text{EDP})$ into the join of a finite part and an infinite part, where the finite part is an infinite simplex with the vertex set $\{\mathcal{M}(T)_{\#T}\}_{T \in \text{Conf}_0}$.

**Definition.** Define the finite part and the infinite part of $\text{log}(\text{EDP})$ by

(10.4.1) $\text{log}(\text{EDP})_{abs} := \text{log}(\text{EDP}) \cap L_{R, \text{abs}}$,

(10.4.2) $\text{log}(\text{EDP})_{\infty} := \text{log}(\text{EDP}) \cap L_{R, \infty}$.

**Lemma.** 1. $\text{log}(\text{EDP})$ is the join of the finite part and the infinite part:

(10.4.3) $\text{log}(\text{EDP}) = \text{log}(\text{EDP})_{\text{abs}} \ast \text{log}(\text{EDP})_{\infty}$.

Here, the join of subsets $A$ and $B$ in real vector spaces $V$ and $W$ is defined by $A \ast B := \{\lambda p + (1 - \lambda)q \in V \oplus W \mid p \in A, q \in B, \lambda \in [0, 1]\}$.

2. The finite part is the infinite simplex of the vertex set $\{\mathcal{M}(S)_{\#S}\}_{S \in \text{Conf}_0}$:

$\text{log}(\text{EDP})_{\text{abs}} = \left\{\sum_{S \in \text{Conf}_0}^{\text{abs}} \mu_S \mathcal{M}(S)_{\#S} \mid \mu_S \in \mathbb{R}_{\geq 0} \text{ and } \sum_{S \in \text{Conf}_0}^{\text{abs}} \mu_S = 1\right\}$.

**Proof.** We prove 1. and 2. simultaneously in two steps A. and B. We show only the inclusion $\text{LHS} \subset \text{RHS}$ since the opposite inclusion $\text{LHS} \supset \text{RHS}$ is trivial due to the closed compact convexity of $\text{log}(\text{EDP})$ (10.3 Assertion 1.).

A. **Finite part.** Let us consider an element $\omega \in \text{log}(\text{EDP})$ of the expression (10.3.2). For $S \in \text{Conf}_0$, recall that $\delta(S, T_n)$ is the $\#$ of connected components of $T_n$ isomorphic to $S$. Let us show that the limit

(10.4.4) $\mu_S := \#S \lim_{n \to \infty} \frac{\delta(S, T_n)}{\#T_n}$

converges to a finite real number $\mu_S$ such that

(10.4.5) $0 \leq \sum_{S \in \text{Conf}_0}^{\text{abs}} \mu_S \leq 1$.

Note that the kabi-map $\overline{K}$ (8.4.1) is also continuous with respect to the classical topology. So, it commutes with the classical limiting process $\lim_{n \to \infty}^{\text{cl}} \frac{\mathcal{M}(T_n)}{\#T_n}$. Recalling the kabi-inversion formula (7.3.1), we calculate

$\overline{K}(\omega) = \overline{K}\left(\lim_{n \to \infty}^{\text{cl}} \frac{\mathcal{M}(T_n)}{\#T_n}\right) = \lim_{n \to \infty}^{\text{cl}} \frac{\overline{K}(\mathcal{M}(T_n))}{\#T_n} = \lim_{n \to \infty}^{\text{cl}} \sum_{S \in \text{Conf}_0}^{\text{abs}} \delta(S, T_n) \mathcal{M}(S)$. 
Here, the convergence on the RHS is the coefficient-wise convergence with respect to the basis $\mathcal{M}(S)$ for $S \in \text{Conf}_0$. This implies the convergence of (10.4.4).

Let $C$ be any finite subset of $\text{Conf}_0$. For any $n \in \mathbb{Z}_{\geq 0}$, one has

$$\sum_{T \in C} \delta(T, T_n) \cdot \sharp T \leq \sharp T_n$$

since the LHS is equal to the cardinality of the vertices of the union of connected components of $T_n$ which is isomorphic to an element of $C$. Dividing both sides by $\sharp T_n$ and taking the limit $n \to \infty$, one has (10.4.5).

Define the finite part of $\omega$ by the absolutely convergent sum

$$(10.4.6) \quad \omega_{\text{finite}} := \sum_{S \in \text{Conf}_0} \mu_S \mathcal{M}(S) \frac{\sharp S}{\sharp S}$$

(apply 10.2 Assertion to (10.4.5)). We remark that the coefficients $\mu_S$ are uniquely determined from $\omega$ and are independent of the sequence $\{T_n\}_{n \in \mathbb{Z}_{\geq 0}}$, due to the formula:

$$(10.4.7) \quad \mathcal{K}(\omega) = \sum_{S \in \text{Conf}_0} \mu_S \mathcal{M}(S) \frac{\sharp S}{\sharp S}.$$
Substituting $n$ and $C$ in $\ast$ by $n(m)$ and $C_m$, respectively, we obtain a sequence of equalities indexed by $m \in \mathbb{Z}_{\geq 0}$. Let us prove:

i) the second term of $\ast$ absolutely converges to $\omega_{\text{finite}}$.

ii) if $\mu_\infty = 0$, then the first term of $\ast$ converges to 0.

iii) if $\mu_\infty \neq 0$, then $T^*_n := T^*_n(C^{c}) \neq \emptyset$ for large $m$ and $\mathcal{M}(T^*_n)/\sharp T^*_n$ converges to an element $\omega_\infty \in \log(\text{EDP}) \cap L_{\mathbb{R},\infty}$.

**Proof of i).** For $m \in \mathbb{Z}_{\geq 0}$, the difference of $\omega_{\text{finite}}$ and the second term of $\ast$ is $\sum S \in \text{Conf}_0 c_S M(S)/\sharp T^n$ where $c_S := \mu_S - \delta(S,T^n_m)\sharp S/\sharp T^n_m$ for $S \in C_m$ and $c_S := \mu_S$ for $S \in \text{Conf}_0 \setminus C_m$. Therefore, using a) and the latter half of b), one sees that the sum $\sum S \in \text{Conf}_0 |c_S|$ is bounded by $2\varepsilon_m$. Then, due to a criterion in 10.2, the difference tends to 0 absolutely as $m \uparrow \infty$. □

**Proof of ii).** Recall $c) \left\|T^*_n(C^{c})/\sharp T^n_m\right\| < 2\varepsilon_m$. The first term of $\ast$ is given by $\frac{M(T^*_n(C^{c}))}{\sharp T^n_m} = \sum S \in \text{Conf}_0 \varphi(S) A(S,T^*_n(C^{c}))/\sharp T^n_m$, where the coefficient of $\varphi(S)$ is either 0 if $T^*_n(C^{c}) = \emptyset$ or equal to $\frac{\sharp T^n_m}{\sharp T^n_m} A(S,T^*_n(C^{c}))/\sharp T^n_m$ otherwise, which is bounded by $2\varepsilon_m q^{n-1}/\sharp \text{Aut}(S)$. So it converges to 0 as $m \uparrow \infty$. □

**Proof of iii).** The sequence of the first term of the RHS of $\ast$ converges to $\omega - \omega_{\text{finite}}$, since the LHS of $\ast$ and the second term of the RHS of $\ast$ converge to $\omega$ and $\omega_{\text{finite}}$, respectively. On the other hand, due to c), one has $\left\|T^*_n(C^{c})/\sharp T^n_m\right\| > \mu_\infty - 2\varepsilon_m$ for sufficiently large $m$, and hence one has $T^*_n(C^{c}) \neq \emptyset$. The first factor is decomposed as:

$$\frac{\mathcal{M}(T^*_n(C^{c}))}{\sharp T^n_m} = \frac{T^*_n(C^{c}) \mathcal{M}(T^*_n(C^{c}))}{\sharp T^n_m}$$

whose first factor converges to $\mu_\infty \neq 0$ due to c). Therefore, the second factor converges to some $\omega_\infty := (\omega - \omega_{\text{finite}})/\mu_\infty$, which belongs to $\log(\text{EDP})$ by definition. Since $\mathcal{K}(\omega) = \mathcal{K}(\omega_\infty)$, $\omega_\infty$ belongs to ker($\mathcal{K}$). □

These complete a proof of the Lemma.

□

### 10.5 Extremal points in $\Omega_\infty = \log(\text{EDP})_\infty$.

A point $\omega$ in a subset $A$ in a real vector space is called an **extremal point** of $A$ whenever an interval $I$ contained in $A$ contains $\omega$ then $\omega$ is a terminal point of $I$.

**Assertion.** The extremal point of $\log(\text{EDP})$ is one of the following:

i) $\frac{M(S)}{\sharp S}$ for an element $S \in \text{Conf}_0$,

ii) $\lim_{n \to \infty} \frac{\mathcal{M}(T_n)}{\sharp T_n}$ for a sequence $T_n \in \text{Conf}_0$ with $\#T_n \to \infty$ ($n \to \infty$).
Proof. For \( \omega \in \overline{\log(E_{DP})} \), if \( \mu_{\infty} \neq 0, 1 \), then \( \omega \) cannot be extremal. If \( \mu_{\infty} = 0 \), due to Corollary 1, the only possibility for \( \omega \) to be extremal is when it is of the form \( \frac{M(s)}{\omega} \) for an element \( S \in \text{Conf}_0 \). In fact, using the uniqueness of the expression (Lemma 3.), \( \frac{M(s)}{\omega} \) can be shown to be extremal.

Suppose \( \mu_{\infty} = 1 \). For any fixed \( S \in \text{Conf}_0 \) and real \( \epsilon > 0 \), let \( T_n(S, \epsilon) \) (resp. \( T_n^-(S, \epsilon) \)) be the subgraph of \( T_n \) consisting of the components \( T \) such that \( A(S, T)/\|T \| \geq a_S + \epsilon \) (resp. \( \leq a_S - \epsilon \)). Let us show that \( \lim_{n \to \infty} \|T_n^+(S, \epsilon)/\|T_n \| = 0 \).

If not, then there exists a subsequence \( \{\hat{n}_i\} \) such that \( \lim_{\hat{n}_i \to \infty} \|T_{\hat{n}_i}^+(S, \epsilon)/\|T_{\hat{n}_i} \| = \lambda > 0 \).

Due to the compactness of \( \log(E_{DP}) \) (Assertion 1.), we can choose a subsequence such that \( \mathcal{M}(T_{\hat{n}_i}^+(S, \epsilon))/\|T_{\hat{n}_i}^+ \| \) and \( \mathcal{M}(T_{\hat{n}_i} \setminus T_{\hat{n}_i}^+(S, \epsilon))/\|T_{\hat{n}_i} \| \) converges to some \( \sum_{T \in \text{Conf}_0} \varphi(T) \cdot b_T \) and \( \sum_{T \in \text{Conf}_0} \varphi(T) \cdot c_T \), respectively, so that

\[
\omega = \lambda \cdot \sum_{T \in \text{Conf}_0} \varphi(T) \cdot b_T + (1 - \lambda) \cdot \sum_{T \in \text{Conf}_0} \varphi(T) \cdot c_T.
\]

In particular, the coefficient of \( \varphi(S) \) has the relation \( a_S = \lambda \cdot b_S + (1 - \lambda) \cdot c_S \).

Since \( |b_S - a_S| \geq \epsilon \), \( \lambda \) cannot be 1. This contradicts the extremity of \( \omega \).

For any finite subset \( C \) of \( \text{Conf}_0 \), put \( \hat{T}_n(C, \epsilon) := T_n \setminus \bigcup_{S \in C} (T_n^+(S, \epsilon) \cup T_n^-(S, \epsilon)) \). Then \( \hat{T}_n(C, \epsilon) \neq \emptyset \) for sufficiently large \( n \), since \( \lim_{n \to \infty} \|T_n^+(C, \epsilon)/\|T_n \| = 1 \) due to the above fact. Let \( \{C_m\}_{m \in \mathbb{Z}_{\geq 0}} \) be an increasing sequence of finite subsets of \( \text{Conf}_0 \) such that \( \bigcup_{m \in \mathbb{Z}_{\geq 0}} C_m = \text{Conf}_0 \) and let \( \{\epsilon_m\}_{m \in \mathbb{Z}_{\geq 0}} \) be a sequence of real numbers with \( \epsilon_m \downarrow 0 \). For each \( m \in \mathbb{Z}_{\geq 0} \), choose any connected component of \( T_n^+(C_m, \epsilon_m) \), say \( \hat{T}_n^+ \), for large \( n \), and put \( \omega_m := \mathcal{M}(T_{\hat{n}_m}^+)/\|\hat{T}_{\hat{n}_m}^+ \| = \sum_{S \in \text{Conf}_0} \varphi(S) \cdot a_s^{(m)} \). By definition \( |a_S - a_s^{(m)}| < \epsilon_m \) for \( S \in C_m \), which implies \( \omega = \lim_{m \to \infty} \omega_m \). There are two cases to consider: i) Suppose \( \exists \{\hat{m}\} \) such that \( \|\hat{T}_{\hat{m}} \| \) is bounded. Since \( \{T \in \text{Conf}_0 \mid \|T \| \leq c \} \) for any constant \( c \) is finite, there exists \( T \in \text{Conf}_0 \) which appears in \( \{T_{\hat{m}}\}_m \) infinitely often. So \( \omega = \mathcal{M}(T)/\|T \| \) and \( K(\omega) = \mathcal{M}(T)/\|T \| \neq 0 \). ii) Suppose \( \|\hat{T}_m \| \to \infty \). Then the formula (10.4.4) and (10.4.7) imply \( K(\omega) = 0 \).

\[ \square \]

10.6 Function value representation of elements of \( \Omega_{\infty} = \overline{\log(E_{DP})}_{\infty} \)

The coefficients \( a_S \) at \( S \in \text{Conf}_0 \) of the sequential limit \( \omega = \lim_{n \to \infty} \mathcal{M}(T_n)/\|T_n \| \) (10.3.2) are usually hard to calculate. However, in certain good cases, we represent the coefficient as a special value of a function in one variable \( t \).

Given an expression of the form (10.3.2) of \( \omega \in \overline{\log(E_{DP})}_{\infty} \) and an increasing sequence of integers \( \{n_m\}_{m=0}^\infty \), we consider the following two formal power series in \( t \).
\[(10.6.1)\]
\[P(t) := \sum_{m=0}^{\infty} \sharp T_m \cdot t^m \in \mathbb{Z}[t],\]

\[(10.6.2)\]
\[P_M(t) := \sum_{m=0}^{\infty} M(T_m) \cdot t^m \in \mathbb{L}_Q[t] = \mathbb{L}_Q[t],\]

where, using the basis expansion (8.2.3), the series \(P_M(t)\) can be expanded as
\[P_M(t) = \sum_{S \in \text{Conf}_0} \varphi(S) P_M(S,t),\]
whose coefficients at \(S \in \text{Conf}_0\) are given by
\[(10.6.3)\]
\[P_M(S,t) := \partial_S P_M(t) = \sum_{m=0}^{\infty} A(S,T_m) \cdot t^m \in \mathbb{Q}[t].\]

Since \(T_n \in \text{Conf}_+\), one has \(P(t) \neq 0\) and its radius of convergence is at most 1.

**Lemma.** Suppose that the series \(P(t)\) has a positive radius of convergence \(r\). Then, for any \(S \in \text{Conf}_0\) (c.f. Remark), we have

i) The series \(P_M(S,t)\) converges at least in the radius \(r\) for \(P(t)\). The radius of convergence of \(P_M(S,t)\) coincides with \(r\), if \(a_S := \lim_{m \to \infty} \frac{M(S,T_m)}{\# T_m} \neq 0\).

ii) The following two limits in LHS and RHS give the same value:
\[(10.6.4)\]
\[\lim_{t \uparrow r} \frac{P_M(S,t)}{P(t)} = \lim_{n \to \infty} \frac{M(S,T_n)}{\# T_n}.\]

Here by the notation \(t \uparrow r\) we mean that the real variable \(t\) tends to \(r\) from below.

iii) The proportion \(P_M(t)/P(t)\) for \(t \uparrow r\) converges to \(\omega\) (10.3.2):
\[(10.6.5)\]
\[\omega = \lim_{t \uparrow r} \frac{P_M(t)}{P(t)} = \sum_{S \in \text{Conf}_0} \varphi(S) \lim_{t \uparrow r} \frac{P_M(S,t)}{P(t)}.\]

**Proof.** Before proceeding to the proof, we recall two general properties of power series:

A) The radius of convergence of \(P(t)\) is \(r := 1/\limsup \frac{\sqrt[n]{\sharp T_m}}{m \to \infty}\) (Hadamard).

B) Since the coefficients \(\sharp T_m\) of \(P(t)\) are non-negative real numbers, \(P(t)\) is an increasing positive real function on the interval \((0,r)\) and \(\lim_{t \uparrow r} P(t) = +\infty\).

We now turn to the proof. Due to the linear relations among \(M(S,T_m)\) for \(S \in \text{Conf}_0\) (8.3.2), it is sufficient to show the lemma only for the cases \(S \in \text{Conf}_0\).

i) Let us show that \(P_M(S,t)\) for \(S \in \text{Conf}_0\) has the radius \(r\) of convergence. Since we have \(M(S,T_m) = A(S,T_m)\) (6.1 Remark 1), using (5.2.1), we have
\[\limsup_{m \to \infty} \frac{\sqrt[m]{M(S,T_m)}}{\# T_m} \leq \limsup_{m \to \infty} \frac{\sqrt[m]{\# T_m}}{\# \text{Aut}(S)} = 1/r.\]
This proves the first half of i). The latter half is shown in the next ii).

ii) We show that the convergence of the sequence \(A(S,T_m)/\sharp T_m\) to some \(a_S \in \mathbb{R}\) implies the convergence of the values of the function \(P_M(S,t)/P(t)\) to
a_\mathcal{S} as t \uparrow r. The assumption implies that for any \varepsilon > 0, there exists N > 0 such that |A(S, T_m) / qT_m - a_\mathcal{S}| \leq \varepsilon for all m \geq N. Therefore,

\[ \left| \frac{PM(S, t)}{P(t)} - a_\mathcal{S} \right| = \left| \frac{QN(t) + \sum_{m=1}^{\infty} \left(A(S, T_m) - a_\mathcal{S} \cdot qT_m\right) t^m}{P(t)} \right| \leq \frac{|QN(t) - \varepsilon \sum_{m=0}^{N-1} \#T_m t^m|}{P(t)} + \varepsilon \]

where \( Q_N(t) := \sum_{m<N} \left(A(S, T_m) - a_\mathcal{S} \cdot qT_m\right) t^m \) is a polynomial in t. Due to statement B) above, the first term of the last line tends to 0 as \( t \uparrow r \). Hence, \(|PM(S, t) / P(t) - a_\mathcal{S}| \leq 2\varepsilon \) for \( t \) sufficiently close to \( r \). This proves \( 10.6.4 \).

If \( a_\mathcal{S} \neq 0 \), then \( \lim_{t \uparrow r} PM(S, t) = \infty \) since \( \lim P(t) = \infty \). Thus, the radius of convergence of \( PM(S, t) \) is less or equal than \( r \). This proves the latter half of i).

iii) We have only to recall that the classical topology on \( \mathcal{L}_\mathbb{R} \) is the same as coefficient-wise convergence with respect to the basis \( \{\varphi(S)\}_{S \in \text{Conf}_0} \). \( \Box \)

**Corollary.** If \( P(t) \) and \( PM(S, t) \) \( (S \in \text{Conf}_0) \) extend to meromorphic functions at \( t = r \), then \( PM(S, t) / P(t) \) is regular at \( t = r \) and one has

\[ \omega = \sum_{S \in \text{Conf}_0} \varphi(S) \frac{PM(S, t)}{P(t)} \bigg|_{t=r} \]

**Proof.** We have to show that \( PM(S, t) / P(t) \) becomes holomorphic at \( t = r \) under the assumption. If it were not holomorphic, it would have a pole at \( t = r \) and hence \( \lim_{t \uparrow r} PM(S, t) / P(t) \) diverges. On the other hand, in view of \( 5.2.2 \), one has the inequality \( 0 \leq PM(S, t) \leq P(t) \cdot q^{|S|-1} \cdot \text{Aut}(S) \) for \( t \in (0, r) \). Then the positivity of \( P(t) \) implies the boundedness \( 0 \leq PM(S, t) / P(t) \leq q^{|S|-1} / \text{Aut}(S) \) for \( t \in (0, r) \). This is a contradiction. \( \Box \)

We sometimes call \( 10.6.6 \) a residual expression of \( \omega \), since the coefficients are given by the proportions of residues of meromorphic functions.

**Remark.**

1. The equality \( 10.6.4 \) gives the following important replacement. Namely, the RHS, which is a sequential limit of rational numbers and is hard to determine in general, is replaced by the LHS, which is the limit of value of a function in a variable \( t \) at the special point \( t = r \) where \( r \) is often a real algebraic number whose defining equation is easily calculable.

2. The convergence of the sequence \( \lim_{n \to \infty} \frac{M(S, T_n)}{#T_n} \) does not imply the convergence of the series \( PM(S, t) \) and \( P(t) \) in a positive radius. Conversely, the convergence of the series \( PM(S, t) \) and \( P(t) \) in a positive radius does not imply the convergence of the sequence \( \lim_{n \to \infty} \frac{M(S, T_n)}{#T_n} \).
§11. Limit space \( \Omega(\Gamma, G) \) for a finitely generated monoid.

We apply the space \( \mathcal{L}_{\mathbb{R}, \infty} \) to the study of finitely generated monoids.

For a pair \((\Gamma, G)\) of a monoid \(\Gamma\) and a finite generating system \(G\) with Assumptions 1, 2, we introduce 1) the limit space \(\Omega(\Gamma, G)\) as a subset of \(\mathcal{L}_{\mathbb{R}, \infty}\),

2) another limit space \(\Omega(\Gamma, G)\) associated with Poincare series \(P_{\Gamma, G}(t)\) of \((\Gamma, G)\), and 3) a proper surjective map \(\pi_\Omega : \Omega(\Gamma, G) \rightarrow \Omega(\Gamma, G)\) (see 11.2 Theorem).

The main result of the present paper is given in 11.5 Theorem, where the sum of elements of a fiber of \(\pi_\Omega\) is expressed by a linear combination of the proportions of residues of the Poincare series \(P_{\Gamma, G}(t)\) and \(P_{\Gamma, G}(t)\) at the poles on the circle of the radius of convergence of the Poincare series.

11.1 The limit space \(\Omega(\Gamma, G)\) for a finitely generated monoid

Let \(\Gamma\) be a monoid with left and right cancellation conditions and let \(G\) be its finite generating system with \(e \notin G\). We denote by \((\Gamma, G)\) the associated colored oriented Cayley graph (2.1 Example 1). In this and the next section, we use \(G \cup G^{-1}\) as the color set and \(q := \#(G \cup G^{-1})\) for the definition of \(\text{Conf}\) in (2.2.1). The set of all isomorphism classes of finite subgraphs of \((\Gamma, G)\) is denoted by \((\Gamma, G)\). Put \((\Gamma, G) := (\Gamma, G) \cap \text{Conf}_0\).

The length of \(\gamma \in \Gamma\) with respect to \(G\) is defined by

\[
\ell_G(\gamma) := \inf \{ n \in \mathbb{Z}_{\geq 0} \mid \gamma = g_1 \cdots g_n \text{ for some } g_i \in G \ (i = 1, \ldots, n) \}
\]

We remark that in the above definition (11.1.1), we admit the expressions of \(\gamma\) only in positive powers of elements of \(G\) (except when \(G\) itself already contains the inverse). This means that we allow only edges whose “orientation” fits with the orientation of the path. In particular, \(\ell_G(\gamma)\) may not coincide with the distance of \(\gamma\) from \(e\) in the Cayley graph. For \(n \in \mathbb{Z}_{\geq 0}\), let us consider the “balls” of radius \(n\) of \((\Gamma, G)\) defined by

\[
\Gamma_n := \{ \gamma \in \Gamma \mid \ell_G(\gamma) \leq n \}.
\]

We shall denote \(\hat{\Gamma}_n := \Gamma_n \setminus \Gamma_{n-1}\) for \(n \in \mathbb{Z}_{\geq 0}\). So far there is no confusion, we shall denote by \(\Gamma_n\) its isomorphism class \([\Gamma_n] \in \text{Conf}_0\) also.

Definition. The set of limit elements for \((\Gamma, G)\) is defined by

\[
\Omega(\Gamma, G) := \mathcal{L}_{\mathbb{R}, \infty} \cap \left\{ \frac{M(\Gamma_n)}{\# \Gamma_n} \mid n \in \mathbb{Z}_{\geq 0} \right\},
\]

where \(\overline{A}\) is the closure of a subset \(A \subset \mathcal{L}_{\mathbb{R}}\) with respect to the classical topology.

\[\text{2 The length } \ell_G(\gamma) \text{ coincides with the distance from } e \text{ for the case } G = G^{-1} \text{ when } \Gamma \text{ is a group. Besides this case, there is an important class of monoids, where both concepts coincide, namely, when the monoid is defined by positive homogeneous relations \([S-I]\).}\]
The limit space $\Omega(\Gamma, G)$ is non-empty if and only if $\Gamma$ is infinite.

Proof. Since $\{\frac{M(\Gamma_n)}{\# \Gamma_n} \mid n \in \mathbb{Z}_{\geq 0}\} \subset \log(EDP)$ and \( \log(EDP) \) is compact (10.3), the sequence $\{\frac{M(\Gamma_n)}{\# \Gamma_n} \mid n \in \mathbb{Z}_{\geq 0}\}$ always has accumulation points. Due to (10.4.4) and (10.4.7), an accumulation point $\omega$ belongs to $L_{R, \infty}$, i.e. it satisfies the kabi-condition $K(\omega) = 0$, if and only if $\# \Gamma_n \to \infty$. ✷

Since $\log(EDP)$ is metrizable, any element $\omega$ in $\Omega(\Gamma, G)$ can be expressed as a sequential limit. That is, there exists a subsequence $n_{m} \uparrow \infty$ of $n \uparrow \infty$ such that (11.1.4)
\[
\omega = \lim_{n_{m} \to \infty} \frac{M(\Gamma_{n_{m}})}{\# \Gamma_{n_{m}}} = \sum_{S \in \langle \Gamma, G \rangle_{0}} \varphi(S) \lim_{n_{m} \to \infty} \frac{A(S, \Gamma_{n_{m}})}{\# \Gamma_{n_{m}}}
\]
where the coefficient of $\varphi(S)$ is convergent for all $S$.

Definition. We call a finitely generated monoid $(\Gamma, G)$ simple (resp. finite) accumulating if $\Omega(\Gamma, G)$ consists of a single (resp. finite number of) element(s).

Assumption 1. From now on until the end of the present paper, we assume that the monoid $\Gamma$ is embeddable into a group. That is, there exists an injective homomorphism from $\Gamma$ into a group. This is obviously satisfied if $\Gamma$ is a group.

In the following Examples 1. and 2., we show that any polynomial growth group and any free group is simple accumulating. We first state some general properties of the set $\Gamma_n$, which are immediate consequences of the definition.

Fact. 1. For $m, n \in \mathbb{Z}_{\geq 0}$, one has a natural surjection:
\[
\Gamma_m \times \Gamma_n \longrightarrow \Gamma_{m+n}, \gamma \times \delta \mapsto \gamma \delta
\]

2. For any $S \in \text{Conf}_0$ with $S \leq \Gamma_k$ ($k \in \mathbb{Z}_{\geq 0}$) and for any $n \in \mathbb{Z}_{\geq 0}$, one has:

(11.1.6) $\# \Gamma_{n-k} \leq \#(\text{Aut}(S)) \cdot A(S, \Gamma_n)$ $\leq \# \Gamma_n$.

Proof. 1. Obvious by definition.

2. By the assumption on $S$, there exists a subgraph $S \subset \Gamma_k$ such that $S = [S]$. Note that $\text{Aut}(S) \simeq \text{Aut}(S) = \{g \in \hat{\Gamma} \mid gS = S\}$ is finite and its action is fixed point free. Consider a map $p$ from $\Gamma$ to the set of subgraphs of $(\Gamma, G)$ defined by $p(g) := gS$, and define an equivalence relation $\sim$ on $\Gamma$ by “$g \sim h \iff gS = hS \iff g^{-1}h \in \text{Aut}(S)$”. Then, one has $A(S, \Gamma_n) \geq \#(\text{Image}(p|_{\Gamma_{n-k}})) = \#(\Gamma_{n-k} / \sim) \geq \#(\Gamma_{n-k}) / \#(\text{Aut}(S))$. This implies the first inequality.

Choose a point $x \in S$. Consider a set $P := \{g \in \Gamma_n \mid gx^{-1}S \subset \Gamma_n\}$. Then, the map $p|_{P} \circ x^{-1} : P \to \text{Aut}(S, \Gamma_n)$ is surjective and $P$ is closed under the right
Let \( (\Gamma, G) \) be a monoid such that \( \lim_{n \to \infty} \frac{\#(\Gamma_n - k)}{\#(\Gamma_n)} = 1 \) for any \( k \in \mathbb{Z}_{\geq 0} \). Then, as a consequence of \((11.1.6)\), one has

\[
(11.1.7) \quad \lim_{n \to \infty} \frac{A(S, \Gamma_n)}{\#(\Gamma_n)} = \frac{1}{\#(\text{Aut}(S))}.
\]

**Example.** 1. If \( \Gamma \) is a group of polynomial growth, then it is simple accumulating for any generating system \( G \) and the limit element is given by

\[
(11.1.8) \quad \omega_{\Gamma, G} := \sum_{S \in \langle \Gamma, G \rangle_0} \frac{1}{\#(\text{Aut}(S))} \varphi(S).
\]

**Proof.** For a group \((\Gamma, G)\) of polynomial growth (i.e. \( \Gamma \) contains a finitely generated nilpotent group of finite index, Wolf and Gromov \([\text{Gr1}]\)), there exist constants \( c, d \in \mathbb{Z}_{> 0} \) such that \( \#(\Gamma_n) = cn^d + o(n^d) \) (Pansu \([\text{P}]\)).

2. Let \( F_f \) be a free group with the generating system \( G = \{g_1^{\pm 1}, \cdots, g_f^{\pm 1}\} \) for \( f \in \mathbb{Z}_{\geq 2} \). Then \((F_f, G)\) is simple accumulating. The limit element is given by

\[
(11.1.9) \quad \omega_{F_f, G} := \sum_{k=0}^{\infty} (2f-1)^{-k} \left( \sum_{S \in \langle \Gamma, G \rangle_0} \frac{\varphi(S)}{d(S)^{2k}} \right),
\]

where \( d(S) := \max\{d(x, y) \mid x, y \in S\} \) is the diameter of \( S \) for \( S \in \langle F_f, G \rangle_0 \).

**Proof.** The induction relation: \( \#(\Gamma_{n+1} - (2f-1)) \#(\Gamma_n) = 2 \) with the initial condition \( \#(\Gamma_0) = 1 \) implies \( \#(\Gamma_n) = f(2f-1)^{n-1} \) for \( n \in \mathbb{Z}_{\geq 0} \) so that \( P_{F_f, G}(t) = \frac{1+4t}{(1-t)(1-(2f-1)t)} \). On the other hand, for \( S \in \langle F_f, G \rangle_0 \) and for \( n \geq [d(S)/2] \)

\[
(11.1.10) \quad A(S, \Gamma_n) = \begin{cases} f(2f-1)^{n-[d(S)/2]}-1 & \text{if } d(S) \text{ is even}, \\ f(2f-1)^{n-[d(S)/2]} & \text{if } d(S) \text{ is odd}. \end{cases}
\]

\[
(11.1.11) \quad \lim_{n \to \infty} \frac{A(S, \Gamma_n)}{\#(\Gamma_n)} = \begin{cases} (2f-1)^{-[d(S)/2]} & \text{if } d(S) \text{ is even}, \\ f^{-1}(2f-1)^{-[d(S)/2]} & \text{if } d(S) \text{ is odd}. \end{cases}
\]

We have only to prove the first formula. Depending on whether \( d(S) \) is even or odd, \( S \) has either one or two central points. Then it is easy to see the following one to one correspondence: an embedding of \( S \) in \( \Gamma_n \) \( \Leftrightarrow \) an embedding of the central point(s) of \( S \) in \( \Gamma_n \) such that the distance from the point to the boundary of \( \Gamma_n \) is at least half of the diameter \([d(S)/2]\). Taking this into account, we can calculate directly the formula.
11.2 The space $\Omega(P_{\Gamma,G})$ of opposite sequences

We introduce another accumulation set $\Omega(P)$, called the space of opposite sequences, associated to certain real power series $P(t)$. Under a suitable assumption on $(\Gamma, G)$, we have a fibration $\pi_\Omega : \Omega(\Gamma, G) \to \Omega(P_{\Gamma,G})$ for the Poincare series $P_{\Gamma,G}$ of $(\Gamma, G)$. We construct semigroup actions on $\Omega(\Gamma, G)$ and $\Omega(P_{\Gamma,G})$ generated by $\tilde{\tau}_\Omega$ and $\tau_\Omega$, respectively, which are equivariant with $\pi_\Omega$.

We start with a general definition. Consider a power series in $t$

$$P(t) = \sum_{n=0}^{\infty} \gamma_n t^n$$

whose coefficients are real numbers. We assume that there exist positive real numbers $u, v$ (depending on $P$) such that $u \leq \gamma_n - 1 / \gamma_n \leq v$ for all $n \in \mathbb{Z}_{\geq 1}$. This, in particular, implies that $P$ is convergent of radius $r$ with $u \leq r \leq v$.

Example. If the sequence $\{\gamma_n\}_{n \in \mathbb{Z}_{\geq 0}}$ is increasing and semi-multiplicative $\gamma_{m+n} \leq \gamma_m \gamma_n$, we may choose $u = 1 / \gamma_1$ and $v = 1$. For example, let $\gamma_n := \# \Gamma_n (n \in \mathbb{Z}_{\geq 0})$ in the setting of 11.1, then (11.1.5) implies semi-multiplicativity.

Associated to $P$, consider a sequence $\{X_n(P)\}_{n \in \mathbb{Z}_{\geq 0}}$ of polynomials:

$$X_n(P) := \sum_{k=0}^{n} \frac{\gamma_n - k}{\gamma_n} s^k, \quad n = 0, 1, 2, \ldots,$$

in the space $\mathbb{R}[s]$ of formal power series, where $\mathbb{R}[s]$ is equipped with the formal classical topology, i.e. the product topology of convergence of every coefficient in classical topology. Since each coefficients of $X_n(P)$ are bounded, i.e. $u^k \leq \frac{\gamma_n - k}{\gamma_n} \leq v^k$, the sequence accumulates to a non-empty compact set:

$$\Omega(P) := \text{the set of accumulation points of the sequence (11.2.2)}.$$

An element $a(s) = \sum_{k=0}^{\infty} a_k s^k$ of $\Omega(P)$ is called an opposite series. The coefficients $\{a_k\}_{k=0}^{\infty}$ satisfies $u^k \leq a_k \leq v^k$. We call $a_1$ the initial of the opposite series $a$, denoted by $\iota(a)$. Let us introduce the space of initials:

$$\Omega_1(P) := \text{the set of accumulation points of the sequence (11.2.2)},$$

which is a compact subset of the positive interval $[u, v]$. The projection map $a \in \Omega(P) \mapsto \iota(a) \in \Omega_1(P)$ is a continuous surjective map.

Assertion. 1. If a sequence $\{X_{n_m}(P)\}_{m \in \mathbb{Z}_{\geq 0}}$ converges to an opposite sequence $a$, then the sequence $\{X_{n_m-1}(P)\}_{m \in \mathbb{Z}_{\geq 0}}$ converges also to an opposite sequence, denoted by $\tau_\Omega(a)$. We have

$$\tau_\Omega(a) = (a - 1) / \iota(a).$$
2. Consider a map
\[ \tau : \Omega(P) \to \overline{\Omega}(P), \quad a \mapsto \iota(a)\tau(a) \]
where \(\overline{\Omega}(P)\) is a closed \(\mathbb{R}\)-linear subspace of \(\mathbb{R}[s]\) generated by \(\Omega(P)\). Then, the map \(\tau\) naturally extends to an endomorphism of \(\overline{\Omega}(P)\).

**Proof.**
1. By definition, the sequence \(\{\gamma_{n-k}/\gamma_{n-m}\}_{m}\) converges to the non-zero initial \(\iota(a) \neq 0\). Then, for any fixed \(k > 0\), the \((k - 1)\)th coefficient of \(\tau(a)\) is given by the limit of sequence \(\{\gamma_{n-k}/\gamma_{n-m}\}_{m}\) converging to \(a_k/a_1\).

2. Let \(\sum_{i \in I} c_i a_i(s) = 0\) be a linear relation among opposite sequences \(a_i(s)\) \((i \in I)\) with \(#I < \infty\), then we also have a linear relation \(\sum_{i \in I} c_i a_i \tau(\iota(a_i(s))) = 0\), since, using the expression (11.2.5), this follows from the original relation \(\sum_{i = 1}^{\infty} c_i a_i(s) = 0\) and another one \(\sum_{i = 1}^{\infty} c_i = 0\), which is obtained by substituting \(s = 0\) in the first relation. This implies that \(\tau\) is extended to a linear map: \(\overline{\Omega}(P) \to \overline{\Omega}(P)\). On the other hand, \(a(s) \in \mathbb{R}[s] \rightarrow (a(s) - a(0))/s \in \mathbb{R}[s]\) is a well-defined continuous map, so that it induces a map \(\text{End}_\mathbb{R}(\overline{\Omega}(P))\).

We return to the setting in (11.2) and consider a Cayley graph \((\Gamma, G)\). For the sequence \(\{\Gamma_n\}_{n \in \mathbb{Z}_{\geq 0}}\), we consider two series (10.6.1) and (10.6.2):

\[
(11.2.6) \quad P_{\Gamma, G}(t) := \sum_{n=0}^{\infty} \#\Gamma_n \cdot t^n,
\]

\[
(11.2.7) \quad P_{\Gamma, G, \mathcal{M}}(t) := \sum_{n=0}^{\infty} \mathcal{M}(\Gamma_n) \cdot t^n.
\]

Here (11.2.6) is well known \(\mathcal{M}\) as the growth (or Poincare) series for \((\Gamma, G)\), and (11.2.7) is the series which we study in the present paper. Due to (11.1.5), it is well known that the growth series converges with positive radius:

\[
(11.2.8) \quad r_{\Gamma, G} := 1 / \lim_{n \to \infty} \sqrt[n]{\#\Gamma_n} \geq 1 / \#\Gamma_1.
\]

Due to (10.6 Lemma i), the series \(P_{\Gamma, G, \mathcal{M}}(t)\) converges in the same radius as \(P_{\Gamma, G}(t)\). This fact can be directly confirmed by using (11.1.6) for \(S \leq [\Gamma_k]\) as

\[
\lim_{n \to \infty} \left(\frac{1}{n} \sqrt[n]{\#\Gamma_{n-k}}\right)^{k-1} \leq \lim_{n \to \infty} \sqrt[n]{\#(\text{Aut}(S))A(S, \Gamma_n)} \leq \lim_{n \to \infty} \sqrt[n]{\#\Gamma_n}.
\]

Let us consider the continuous linear projection map:

\[
(11.2.9) \quad \pi : \mathcal{L}_R(\Gamma, G) \to \mathbb{R}[s], \quad \sum_{S \in \text{Conf}_0} \varphi(S) \cdot a_S \mapsto \sum_{k=0}^{\infty} a_{\Gamma_k} s^k.
\]

In order that the map \(\pi\) induces the map \(\pi_\Omega\) (11.2.12), we consider the next two conditions \(\mathbf{S}\) and \(\mathbf{I}\) on the graph \((\Gamma, G)\).

First, let us reformulate the concept of dead element (c.f. Bogopolski [Bo], [E2]) to a monoid: an element \(g \in \Gamma\) is called dead with respect to \(G\) if \(\ell_G(gx) \leq \ell_G(g) \forall x \in G\). We denote by \(D(\Gamma, G)\) the set of dead elements in \(\Gamma\).

\[^3\text{The author is grateful to Takefumi Kondo for the information on some works on the subject.}\]
• **S:** The portion \( \frac{\#(\Gamma_1 \cap D(\Gamma, G))}{\#(\Gamma_n)} \) tends to 0 as \( n \to \infty \).

• **I:** For any connected subgraph \( S \) of \( (\Gamma, G) \) and any element \( g \in \hat{\Gamma} \), the equality \( S\Gamma_1 = gS\Gamma_1 \) implies \( S = gS \), where \( S\Gamma_1 := \cup_{\alpha \in S} \alpha \Gamma_1 \).

**Assumption 2.** From now on until the end of the present paper, we assume the conditions \( S \) and \( I \) hold for \( (\Gamma, G) \).

**Remark.** 1. Bogopolski ([Bo] Question(2)) asked whether \( S \) holds for arbitrary finite generating system \( G \) of a group \( \Gamma \). We ask the same question for a monoid \( \hat{\Gamma} \) satisfying Assumption 1. and any finite generating system \( G \).

2. Since \( \text{Aut}(S) \) is a finite subgroup of \( \hat{\Gamma} \) for \( S \in (\Gamma, G)_0 \), it is trivial if \( \hat{\Gamma} \) is torsion free. Then, \( I \) holds automatically for arbitrary finite generating system.

3. If \( \Gamma \) has a torsion element \( g \) of order \( d > 1 \), define a new generating system \( G' := \cup_{i,j=0,\ldots,d-1}(g^i\Gamma_1 g^j) \setminus \{e\} \) for a given \( G \). Then, the new unit ball \( \Gamma'_1 := G' \cup \{e\} \) satisfies \( \Gamma'_1 = g\Gamma'_1 \). That is, the condition \( I \) fails for \( S := \{e\} \). This suggests that in order to satisfy \( I \), \( G \) should be small relative to torsion elements. It is an open question whether, for any finitely generated infinite group \( \Gamma \), there always exists a generating system \( G \) satisfying \( I \).

**Notation.** We define the fattening \( S\Gamma_1 \) for \( S \in (\Gamma, G)_0 \) by the isomorphism class \([S\Gamma_1]\) for any representative \( S \) of \( S \) (the isomorphism class \([S\Gamma_1]\) does not depend on a choice of \( S \) due to the embeddability of \( \Gamma \) into a group).

We regard \( L_\mathbb{R}(\Gamma, G) \) as an \( \mathbb{R}[s] \)-module by letting \( s \) act on the basis by \( \varphi(S) \mapsto \varphi(S\Gamma_1) \) and extending the action formally to \( \mathbb{R}[s] \). However, the map \( \pi \) \[ \text{(11.2.9)} \] is not an \( \mathbb{R}[s] \)-homomorphism \( (S\Gamma_1 = \Gamma_{k+1} \) does not imply \( S = \Gamma_k \)).

Let us state some important consequences of the assumptions \( S \) and \( I \). Recall the notation \[ \text{(5.1.1)} \) and \[ \text{(5.1.2)} \).

**Assertion.** For any \( S \in (\Gamma, G)_0 \), one has the inequalities:

\[
(11.2.10) \quad 0 \leq A(S\Gamma_1, \Gamma_n) - A(S, \Gamma_{n-1}) \leq \#S \cdot \#(\hat{\Gamma}_n \cap D(\Gamma, G)).
\]

**Proof.** Consider a map \( S \in \mathcal{A}(S, \Gamma_{n-1}) \mapsto S\Gamma_1 \in \mathcal{A}(S\Gamma_1, \Gamma_n) \). Then the condition \( I \) implies the injectivity of the map. This implies the first inequality. Any element of \( \mathcal{A}(S\Gamma_1, \Gamma_n) \) is expressed as \( S\Gamma_1 \) for a unique \( S \subset \Gamma_n \) with \( [S] = S \). If \( S\Gamma_1 \) is not in the image of the above map (i.e. \( S \nsubseteq \Gamma_{n-1} \)), then \( S \cap \Gamma_n \neq \emptyset \) is a subset of \( D(\Gamma, G) \). Thus, such \( S \) is of the form \( dS^{-1}S_0 \) for some \( d \in \hat{\Gamma}_n \cap D(\Gamma, G) \) and some \( s \in S_0 \) for a fixed \( S_0 \) with \( [S_0] = S \). Thus the number of such \( S\Gamma_1 \) is at most \( \#(S) \cdot \#(\hat{\Gamma}_n \cap D(\Gamma, G)) \). This implies the second inequality. \( \square \)
Corollary. For \( n, k \in \mathbb{Z}_{\geq 0} \) with \( n - k \geq 0 \), one has the inequalities:

\[
(11.2.11) \quad 0 \leq A(\Gamma_k, \Gamma_n) - \#(\Gamma_{n-k}) \leq \#(\Gamma_{k-1}) \#(\Gamma_n \cap D(\Gamma, G)).
\]

Proof. We show by induction on \( k \), where \( k = 0 \) is trivial (put \( \#\Gamma_{-1} = 0 \)). Assume for \( k - 1 \). Let \( n \) be an integer with \( n \geq k \). Applying (11.2.10) for \( S = \Gamma_{k-1} \), one has \( 0 \leq A(\Gamma_k, \Gamma_n) - A(\Gamma_{k-1}, \Gamma_{n-1}) \leq \#\Gamma_{k-1} \cdot \#(\Gamma_n \cap D(\Gamma, G)) \). This together with the induction hypothesis implies (11.2.11). \( \square \)

Under Assumptions 1 and 2, we show the main result of the present section: the map \( \pi \) (11.2.9) induces the fibration map \( \pi_\Omega : \Omega(\Gamma, G) \to \Omega(P_1, G) \). The fibration is the key structure of the whole present paper.

**Theorem.** 1. If \( \lim_{n \to \infty} \frac{\mathcal{M}(\Gamma_{nm})}{\#_{n_m}} \) converges to an element \( \omega \in \Omega(\Gamma, G) \), then \( \lim_{n \to \infty} X_{nm}(P_1, G) \) converges to \( \pi(\omega) \in \mathbb{R}[s] \). We denote by

\[
(11.2.12) \quad \pi_\Omega : \Omega(\Gamma, G) \to \Omega(P_1, G)
\]

the induced map. The \( \pi_\Omega := \pi|_{\Omega(\Gamma, G)} \) is a surjective and continuous map.

2. If a sequence \( \left\{ \frac{\mathcal{M}(\Gamma_{nm})}{\#_{n_m}} \right\} \) converges to an element \( \omega \in \Omega(\Gamma, G) \), then the sequence \( \left\{ \frac{\mathcal{M}(\Gamma_{nm-1})}{\#_{n_{m-1}}} \right\} \) converges also to an element, depending only on \( \omega \), denoted by \( \tilde{\pi}_\Omega(\omega) \). For \( \omega = \sum_{S \in \{\Gamma, G\}_0} a_S \varphi(S) \in \Omega(\Gamma, G) \), one has

\[
(11.2.13) \quad \tilde{\pi}_\Omega(\omega) = \frac{1}{\iota(\pi_\Omega(\omega))} \sum_{S \in \{\Gamma, G\}_0} a_S \varphi(S).
\]

Using the notation \( \partial_S \) and \( \partial_{\pi_\Omega} \) for \( S \in \{\Gamma, G\}_0 \) in §8.1, (11.2.13) is equivalent to

\[
(11.2.13) \quad \partial_S(\tilde{\pi}_\Omega) = \frac{1}{\iota(\pi_\Omega(\omega))} \partial_{\pi_\Omega} \varphi(S).
\]

Then, \( \pi_\Omega \) (11.2.12) is equivariant with respect to the actions \( \tilde{\pi}_\Omega \) and \( \pi_\Omega \).

3. Let us denote by \( \overline{\mathbb{R}} \Omega(\Gamma, G) \) the closed \( \mathbb{R} \)-linear subspace of \( \mathcal{L}_{\mathbb{R}, \infty} \) generated by \( \Omega(\Gamma, G) \). Define a map \( \tilde{\tau} \) from \( \Omega(\Gamma, G) \) to \( \overline{\mathbb{R}} \Omega(\Gamma, G) \) by

\[
(11.2.14) \quad \tilde{\tau}(\omega) := \iota(\pi_\Omega(\omega)) \tilde{\pi}_\Omega(\omega).
\]

Then, \( \tilde{\tau} \) naturally extends to an \( \mathbb{R} \)-linear endomorphism of \( \overline{\mathbb{R}} \Omega(\Gamma, G) \).

4. The restriction of \( \pi \) (11.2.9) (= the \( \mathbb{R} \)-linear extension of \( \pi_\Omega \)):

\[
(11.2.15) \quad \pi : \overline{\mathbb{R}} \Omega(\Gamma, G) \to \overline{\mathbb{R}} \Omega(P_1, G)
\]

is equivariant with respect to the endomorphisms \( \tilde{\tau} \) and \( \tau \), i.e. \( \tau \circ \pi = \pi \circ \tilde{\tau} \).
Proof. 1. Using (8.2.3), (11.2.2) and (11.2.6), we see that the difference \( \pi \left( \frac{M(\Gamma_k)}{\#\Gamma_k} \right) - X_n(P_{\Gamma, G}) \) is a polynomial in \( s \) of degree \( n \) whose \( k \)th coefficient is \( A(\Gamma_k, \Gamma_n) - \#\Gamma_n \kappa \). Let \( n = n_m \) and take the limit by letting \( m \to \infty \). Applying (11.2.11) and the assumption \( S \), we see that this tends to 0. That is, \( k \)th coefficient of \( \chi_{(\Gamma_k, \Gamma_n)} \) tends to the coefficient \( a_{\Gamma_k} \) at \( \Gamma_k \). That is, \( \chi_{(\Gamma_k, \Gamma_n)} \) converges to the \( \pi \)-image of \( \omega \). Thus the map \( \pi_{\Omega} \) is defined. To show the surjectivity of \( \pi_{\Omega} \), any subsequence \( \{ \chi_{(\Gamma_{n_m}, \Gamma_n)} \}_m \) converging to an opposite sequence, we choose a convergent sub-subsequence \( \{ \chi_{(\Gamma_{n_{m_l}}, \Gamma_n)} \}_l \) due to the compactness of \( \log(\text{EDP}) \).

2. For \( S \in (\Gamma, G)_0 \) and \( n \in \mathbb{Z}_{\geq 1} \), one has

\[
\left( \frac{A(S, \Gamma_{n-1})}{\#\Gamma_{n-1}} \right) = \left( \frac{A(S, \Gamma_{n-1})}{\#\Gamma_{n-1}} - \frac{A(S, \Gamma_n) - A(S, \Gamma_{n-1})}{\#\Gamma_n} \right) / \#\Gamma_{n-1}.
\]

Let the sequence \( \{ \chi_{(\Gamma_{n_m})} \}_m \) associated to a subsequence \( \{ n_m \}_m \subset \mathbb{Z}_{\geq 0} \) of \( \mathbb{Z}_{\geq 0} \) converges to an element \( \omega = \sum_{S \in (\Gamma, G)_0} a_{S\varphi}(S) \in \Omega(\Gamma, G) \). Let \( n = n_m \) in *) and let the index \( m \) run to \( \infty \). The first (resp. second) term in the bracket in the RHS of *) converges to \( a_{S\varphi} \) (resp. 0 due to (11.2.10) and the assumption \( S \)).

The denominator of the RHS of *) converges to the initial \( (\pi(\omega)) \) (11.2.4). Consequently, the RHS of *) converges to \( \frac{1}{(\pi(\omega))} a_{S\varphi} \) for all \( S \). This implies the convergence of \( \lim_{m \to \infty} \left( \frac{M(\Gamma_{n_m})}{\#\Gamma_{n_m}} \right) \) and the formula (11.2.13) and (11.2.13)\*.

Let \( a = \pi_{\Omega}(\omega) := \sum_{k=0}^{\infty} a_{\Gamma_k} s^k \). Comparing the formulae (11.2.5) and (11.2.13), one calculates: \( \pi_{\Omega}(\tilde{\tau}(\omega)) = \frac{1}{(\pi(\omega))} \sum_{k=0}^{\infty} a_{\Gamma_k} s^k = \frac{1}{(\pi(\omega))} \sum_{k=0}^{\infty} a_{\Gamma_k+1} s^k = \frac{1}{(\pi(\omega))} \sum_{i=1}^{\infty} \sum_{k=0}^{\infty} a_{\Gamma_i} s^k = \tau(a) = \tau(\pi_{\Omega}(\omega)) \). This implies that the map \( \pi_{\Omega} \) is equivariant with the \( (\tilde{\tau}, \tau) \)-action.

3. Let (r): \( \sum_{i \in I} c_i \omega_i = 0 \) be a linear relation for \( \omega_i \in \Omega(\Gamma, G) \) and \( c_i \in \mathbb{R} \) \( (i \in I) \) with \( \#(I) < \infty \). Let us show the linear relation (s): \( \sum_{i \in I} c_i \tilde{\tau}(\omega_i) = 0 \). Let us expand \( \omega_i = \sum_S a_{S, i} \varphi(S) \). Then, the relation (r) is expressed as the relations \( \sum_{i \in I} c_i a_{S, i} = 0 \) of coefficients for all \( S \in (\Gamma, G)_0 \). Then the relation (s) is expressed as \( \sum_{i \in I} c_i a_{S\varphi, i} = 0 \) for all \( S \in (\Gamma, G)_0 \), which is a part of the former relations of the coefficients and is automatically satisfied.

This implies that \( \tilde{\tau} \) extends to a linear map \( \mathbb{R} \Omega(\Gamma, G) \to \mathbb{R} \Omega(\Gamma, G) \). On the other hand, the correspondence \( \sum_{S \in (\Gamma, G)} a_{S\varphi}(S) \mapsto \sum_{S \in (\Gamma, G)} a_{S\varphi} \varphi(S) \) defines a redefined continuous linear map from a closed subspace of \( L_\mathbb{R} \) to itself, which induces the endomorphism \( \tilde{\tau} \in \text{End}_{\mathbb{R}}(\mathbb{R} \Omega(\Gamma, G)) \).

4. Let the notation be as in 1. Comparing (11.2.5)* and (11.2.14), one calculates: \( \pi(\tilde{\tau}(\omega)) = \pi(\varphi(\pi(\omega))) = \pi(\varphi(\pi(\omega))) = \pi(\varphi(\pi(\omega))) = \varphi(\pi(\omega)) = \tau(a) = \tau(\pi(\omega)) \). This implies the equivariance of \( \pi. \)
The map $\pi_{\Omega}$ (11.2.12) is conjecturally a finite map. In that case, the sum of elements in a fiber is called a trace, and we, in 11.5, represent the traces by suitable “residue values” of the functions (11.2.6) and (11.2.7). The key to understand this formula is the “duality” between the limit space $\Omega(P_{\Gamma,G})$ and the space of singularities $\text{Sing}(P_{\Gamma,G})$ of the series $P_{\Gamma,G}(t)$ on the circle of the convergent radius $r_{\Gamma,G}$. In next sections 11.3 and 11.4, we study the “duality” in case $\Omega(P_{\Gamma,G})$ is finite (see 11.4 Theorem and (11.4.3) and (11.4.4)).

In the following, we give an example of $(\Gamma, G)$, where $\Omega(P_{\Gamma,G})$ consists of two elements $a^{[0]}$ and $a^{[1]}$, and $\tau_{\Omega}$ acts on $\Omega(P_{\Gamma,G})$ as their transposition. However, we note that $\tau^2 \neq \text{id}$ and $\det(t \cdot \text{id} - \tau) = t^2 - 1/2$.

**Example.** (Machi) Let $\Gamma := \mathbb{Z}/2\mathbb{Z} \ast \mathbb{Z}/3\mathbb{Z}$ and $G := \{a, b^{\pm 1}\}$ where $a, b$ are the generators of $\mathbb{Z}/2\mathbb{Z}$ and $\mathbb{Z}/3\mathbb{Z}$, respectively. Then, Machi has shown

$$P_{\Gamma,G}(t) := \sum_{k=0}^{\infty} \# \Gamma_k t^k = \frac{(1+t)(1+2t)}{(1-2t)(1-t)},$$

so that $\# \Gamma_{2k} = 7 \cdot 2^k - 6$ and $\# \Gamma_{2k+1} = 10 \cdot 2^k - 6$ for $k \in \mathbb{Z}_{\geq 0}$. Then, one has

$$\Omega_1(P_{\Gamma,G}) = \left\{ i(a^{[0]}):= \lim_{n \to \infty} \frac{\# \Gamma_{2n-1}}{\# \Gamma_{2n}} = \frac{5}{7} \right., \left. i(a^{[1]}):= \lim_{n \to \infty} \frac{\# \Gamma_{2n+1}}{\# \Gamma_{2n+2}} = \frac{7}{10} \right\},$$

and, hence $h_{\Gamma,G} = 2$. In fact, $\Omega(P_{\Gamma,G})$ consists of two opposite sequences:

$$a^{[0]}(s) := \sum_{k=0}^{\infty} 2^{-k} s^{2k} + \frac{7}{10} \sum_{k=0}^{\infty} 2^{-k} s^{2k} = (1 + \frac{5}{7} s)/(1 - \frac{5}{7} s^2) = \frac{7 + \sqrt{2}}{10} + \frac{7 - \sqrt{2}}{10} \sqrt{s}$$

$$a^{[1]}(s) := \sum_{k=0}^{\infty} 2^{-k} s^{2k} + \frac{7}{10} \sum_{k=0}^{\infty} 2^{-k} s^{2k} = (1 + \frac{5}{7} s)/(1 - \frac{5}{7} s^2) = \frac{7 + \sqrt{2}}{10} + \frac{7 - \sqrt{2}}{10} \sqrt{s}$$

### 11.3 Finite rational accumulation

We introduce the concept of a finite rational accumulation, and study the series $P(t)$ (11.2.1) from that viewpoint. First, we start with preliminary definitions.

**Definition.**

1. A subset $U$ of $\mathbb{Z}_{\geq 0}$ is called a rational subset if the sum $U(t) := \sum_{n \in U} t^n$ is the Taylor expansion at 0 of a rational function in $t$.

2. A finite rational partition of $\mathbb{Z}_{\geq 0}$ is a finite collection $\{U_a\}_{a \in \Omega}$ of rational subsets $U_a \subset \mathbb{Z}_{\geq 0}$ indexed by a finite set $\Omega$ such that there is a finite subset $D$ of $\mathbb{Z}_{\geq 0}$ so that one has the disjoint decomposition $\mathbb{Z}_{\geq 0} \setminus D = \bigcup_{a \in \Omega} (U_a \setminus D)$.

**Assertion.** For any rational subset $U$ of $\mathbb{Z}_{\geq 0}$, there exist a positive integer $h$, a subset $u \subset \mathbb{Z}/h\mathbb{Z}$ and a finite subset $D \subset \mathbb{Z}_{\geq 0}$ such that $U \setminus D = \bigcup_{[e] \in u} U^{[e]} \setminus D$, where $[e]$ denotes the element of $\mathbb{Z}/h\mathbb{Z}$ corresponding to $e \in \mathbb{Z}$ and $U^{[e]} := \{n \in \mathbb{Z}_{\geq 0} | n \equiv e \mod h\}$. We call $\bigcup_{[e] \in u} U^{[e]}$ the standard expression of $U$.

**Proof.** The fact that $U(t)$ is rational implies that the function $\chi : \mathbb{Z}_{\geq 0} \to \{0, 1\}$ ($\chi(n) = 1 \iff n \in U$) is recursive, i.e. there exist $N \in \mathbb{Z}_{\geq 1}$ and numbers
\[ \alpha_1, \ldots, \alpha_N \] such that one has the recursive relation \( \chi(n) + \chi(n-1)\alpha_1 + \cdots + \chi(n-N)\alpha_N = 0 \) for sufficiently large \( n \gg 0 \). Since the range of \( \chi \) is finite, there exist two large numbers \( n > m \) such that \( \chi(n-i) = \chi(m-i) \) for \( i = 0, \ldots, N \). Due to the recursive relation, this means \( h := n - m \)-periodic after \( m \).

**Corollary.** Any finite rational partition of \( \mathbb{Z}_{\geq 0} \) has a subdivision of the form \( \mathcal{U}_h := \{ U^e \} | e | Z/h \mathbb{Z} \) for some \( h \in \mathbb{Z}_{>0} \), called a period of the partition. If \( h \) is the minimal period, \( \mathcal{U}_h \) is called the standard subdivision of the partition.

**Definition.** A sequence \( \{ X_n \}_{n \in \mathbb{Z}_{\geq 0}} \) in a Hausdorff space is finite rationally accumulating if the sequence accumulates to a finite set, say \( \Omega \), such that for a system of open neighborhoods \( \mathcal{V}_a \) for \( a \in \Omega \) with \( \mathcal{V}_a \cap \mathcal{V}_b = \emptyset \) if \( a \neq b \), the system \( \{ U_a \}_{a \in \Omega} \) for \( U_a := \{ n \in \mathbb{Z}_{\geq 0} \mid X_n \in \mathcal{V}_a \} \) is a finite rational partition of \( \mathbb{Z}_{\geq 0} \). We say also that \( \Omega \) is a finite rationally accumulation set of period \( h \).

The next and 11.5 Lemmas are key facts, which justify the introduction of the concept “rational accumulation”. They are also the starting point of the concept of periodicity which is the thorough bass of the whole study in sequel.

**Lemma.** Let \( P(t) \) be a power series in \( t \) as given in [11.2.1]. If \( \Omega(P) \) is finite, then it is a finite rationally accumulation set with respect to the standard partition \( \mathcal{U}_h \) of \( \mathbb{Z}_{\geq 0} \) for some \( h > 0 \), and \( \tau_\Omega \) acts transitively on \( \Omega(P) \) of period \( h \).

**Proof.** Recall the \( \tau_\Omega \)-action on the set \( \Omega(P) \) in 11.2. Since \( \Omega(P) \) is finite, there exists a non-empty \( \tau_\Omega \)-invariant subset of \( \Omega(P) \). More explicitly, there exists an element \( a \in \Omega(P) \) and a positive integer \( h \in \mathbb{Z}_{>0} \) such that \( (\tau_\Omega)^h a = a \neq (\tau_\Omega)^h a \) for \( 0 < h' < h \). Put \( U_a := \{ n \in \mathbb{Z}_{\geq 0} \mid X_n(P) \in \mathcal{V}_a \} \) where \( \{ \mathcal{V}_a \}_{a \in \Omega(P)} \) is a system of open neighborhoods of points of \( \Omega(P) \) such that \( \mathcal{V}_a \cap \mathcal{V}_b = \emptyset \) for any \( a \neq b \in \Omega(P) \). By the definition of \( \tau_\Omega \), the relation \( (\tau_\Omega)^h a = a \) implies that the sequence \( \{ X_{n-h}(P) \}_{n \in U_a} \) converges to \( a \). That is, there exists a positive number \( N \) such that for any \( n \in U_a \) with \( n > N \), \( n-h \) is contained in \( U_a \).

Consider the set \( A := \{ [e] \in \mathbb{Z}/h \mathbb{Z} \mid \text{there are infinitely many elements of } U_a \text{ which are congruent to } [e] \text{ modulo } h \} \). Then, \( U_a \) is, up to a finite number of elements, equal to the rational set \( \cup_{[e] \in A} U^{[e]} \). This implies \( A \neq \emptyset \). Further more, \( U_{(\tau_\Omega)^h a} \) is also, up to a finite number of elements, equal to the rational set \( \cup_{[e] \in A} U^{[e-h]} \). Then, the union \( \cup_{i=0}^{h-1} U_{(\tau_\Omega)^i a} \) already covers \( \mathbb{Z}_{\geq 0} \) up to finite elements. Since there should not be an overlapping, \( \# A = 1 \), say \( A = \{ [0] \} \).

If a subsequence \( \{ X_{n_m}(P) \} \) converges to an element in \( \Omega(P) \), then there is at least one \( [e] \in \mathbb{Z}/h \mathbb{Z} \) such that \( \#(\{ n_m \}_{m=0}^{\infty} \cap U^{[e]}) = \infty \) so that it converges to \( (\tau_\Omega)^{h-1} a \). That is, \( \Omega(P) \) is equal to the set \( \{ a, (\tau_\Omega)^h a, \cdots, (\tau_\Omega)^{h-1} a \} \), which is a finite rationally accumulating set with the \( h \)-periodic action of \( \tau_\Omega \).
In the sequel, we analyze the finite accumulation set $\Omega(P)$ in detail.

**Assertion.** Let $P(t)$ be a power series in $t$ as given in (11.2.1).

1. $\Omega(P)$ is a finite rationally accumulation set of period $h \in \mathbb{Z}_{\geq 1}$ if and only if $\Omega_1(P)$ is. We say $P$ is finite rationally accumulating of period $h$.

2. Let $P$ be finite rationally accumulating of period $h \in \mathbb{Z}_{\geq 1}$. Then the opposite series $a^c = \sum_{k=0}^{\infty} a_k^c s^k$ in $\Omega(P)$ associated to the rational subset $U^c$ for $[c] \in \mathbb{Z}/h\mathbb{Z}$ of the $h$-partition of $\mathbb{Z}_{\geq 0}$ converges to a rational function

\[(11.3.1) \quad a^c(s) = \frac{A^c(s)}{1 - r^h s^h},\]

where the numerator $A^c(s)$ is a polynomial in $s$ of degree $h-1$ given by

\[(11.3.2) \quad A^c(s) := \sum_{j=0}^{h-1} \left( \prod_{i=1}^{h} a_i^{[e-i+1]} \right) s^j \quad \& \quad r^h := \prod_{i=0}^{h-1} a_i^{[1]}.
\]

The $h$th positive root $r > 0$ of (11.3.3) is the radius of convergence of $P(t)$.

3. If the period $h$ is minimal, then the opposite sequences $a^c(s)$ for $[c] \in \mathbb{Z}/h\mathbb{Z}$ are mutually distinct. That is, $\Omega(P) \simeq \mathbb{Z}/h\mathbb{Z}$, $a^c(s) \leftrightarrow [c]$ and the standard partition $U_h$ is the exact partition of $\mathbb{Z}_{\geq 0}$ for the opposite series $\Omega(P)$.

**Proof.** 1. The necessity is obvious. To show sufficiency, assume that $\{\gamma_{n-1}/\gamma_n\}_{n \in \mathbb{Z}_{\geq 0}}$ accumulate finite rationally of period $h$. Let the subsequence $\{\gamma_{n-1}/\gamma_n\}_{n \in U^c}$ for $[c] \in \mathbb{Z}/h\mathbb{Z}$ accumulate to a unique value $a_1^{[c]}$.

For any $k \in \mathbb{Z}_{\geq 0}$, one has the obvious relation:

\[
\frac{\gamma_{n-k}}{\gamma_n} = \frac{\gamma_{n-1}}{\gamma_n} \cdot \frac{\gamma_{n-2}}{\gamma_{n-1}} \cdots \frac{\gamma_{n-k}}{\gamma_{n-k+1}}.
\]

For $n \in U^c = \{n \in \mathbb{Z}_{\geq 0} \mid n \equiv e \mod h\}$ for $[c] \in \mathbb{Z}/h\mathbb{Z}$, we see that the RHS converges to $a_1^{[c]} a_1^{[e-1]} \cdots a_1^{[e-k+1]}$. Then, for $[c] \in \mathbb{Z}/h\mathbb{Z}$ and $k \in \mathbb{Z}_{\geq 0}$, by putting

\[(11.3.4) \quad a_k^{[c]} := a_1^{[c]} a_1^{[e-1]} \cdots a_1^{[e-k+1]},
\]

the sequence $\{X_n(P)\}_{n \in U^c}$ converges to $a^c := \sum_{k=0}^{\infty} a_k^{[c]} s^k$ with $a_1^{[c]} = t(a^{[c]})$.

2. Define $r^h$ by the relation (11.3.3). Then, the formula (11.3.4) implies the "periodicity" $a_{mh+k} = r^{mh} a_k^{[c]}$ for $m \in \mathbb{Z}_{\geq 0}$. This implies (11.3.1).

To show that $r$ is the radius of convergence of $P(t)$, it is sufficient to show:

**Fact.** Let $P(t)$ be finite rationally accumulating of period $h$. Define $r \geq 0$ by the relation (11.3.3). There exist positive real constants $c_1$ and $c_2$ such that for any $k \in \mathbb{Z}_{\geq 0}$ there exists $n(k) \in \mathbb{Z}_{\geq 0}$ and for any integer $n \geq n(k)$, one has $c_1 r^k \leq \frac{\gamma_{n-k}}{\gamma_n} \leq c_2 r^k$. 

Proof. Choose \( c_1, c_2 \in \mathbb{R}_{>0} \) satisfying \( c_1 < \min \{ a_{i}^{[e]} \mid e \in \mathbb{Z}/h\mathbb{Z}, i \in \mathbb{Z} \cap [0, h-1] \} \) and \( c_2 > \max \{ a_{i}^{[e]} \mid e \in \mathbb{Z}/h\mathbb{Z}, i \in \mathbb{Z} \cap [0, h-1] \}. \)

3. Suppose \( a_{[e]}^{[e]}(s) = a_{[f]}^{[f]}(s) \) for some \([e], [f] \in \mathbb{Z}/h\mathbb{Z].\) Then, by comparing the coefficients of \( A_{[e]}^{[e]}(s) \) and \( A_{[f]}^{[f]}(s), \) we get \( a_{i}^{[e]} = a_{i}^{[f]} \) for \( i = 0, \ldots, h-1. \) This means \( e - f \) is a period. The minimality of \( h \) implies \([e - f] = 0.\)

Even if, as in the Assertion, the opposite series \( a_{[e]}^{[e]}(s) \) for \([e] \in \mathbb{Z}/h\mathbb{Z} \) are mutually distinct for the minimal period \( h \) of \( P(t) \), they may be linearly dependent. This phenomenon occurs at the zero-loci of the determinant

\[
(11.3.5) \quad D_{h}(a_{1}^{[0]}, \ldots, a_{1}^{[h-1]}) := \det \left( \prod_{i=1}^{h} a_{1}^{[e-i+1]} \right)_{e, f \in \{0, 1, \ldots, h-1\}}.
\]

Regarding \( a_{1}^{[0]}, \ldots, a_{1}^{[h-1]} \) as indeterminates, \( D_{h} \) is an irreducible homogeneous polynomial of degree \( h(h - 1)/2 \), which is neither symmetric nor anti-symmetric, but anti-invariant under a cyclic permutation (depending on the parity of \( h \)). Let us formulate more precise statements for an arbitrary field \( K \).

**Assertion.** Let \( h \in \mathbb{Z}_{>0} \). For an \( h \)-tuple \( \bar{a} = (a_{1}^{[0]}, \ldots, a_{1}^{[h-1]}) \in (K^{\times})^{h} \), define polynomials \( A_{[e]}^{[e]}(s) ([e] \in \mathbb{Z}/h\mathbb{Z}) \) and \( r^{h} \in K^{\times} \) by (11.3.2) and (11.3.3).

i) In the ring \( K[s] \), the greatest common divisors \( \gcd(A_{[e]}^{[e]}(s), 1-r^{h}s^{h}) \) and \( \gcd(A_{[e]}^{[e]}(s), A_{[e]}^{[e]+1}(s)) \) for all \([e] \in \mathbb{Z}/h\mathbb{Z} \) are the same up to factors in \( K^{\times} \). Let \( \delta_{a}(s) \) be the common divisor whose constant term is normalized to \( 1 \). Put

\[
(11.3.6) \quad \Delta_{a}^{op}(s) := (1-r^{h}s^{h})/\delta_{a}(s).
\]

ii) For \([e] \in \mathbb{Z}/h\mathbb{Z}, \) let \( a_{[e]}^{[e]}(s) = b_{[e]}^{[e]}(s)/\Delta_{a}^{op}(s) \) be the reduced expression (i.e. \( b_{[e]}^{[e]}(s) \) is a polynomial of degree \( < \deg(\Delta_{a}^{op}) \) and \( \gcd(b_{[e]}^{[e]}(s), \Delta_{a}^{op}(s)) = 1 \)). Then, the polynomials \( b_{[e]}^{[e]}(s) \) for \([e] \in \mathbb{Z}/h\mathbb{Z} \) span the space \( K[s]_{<\deg(\Delta_{a}^{op})} \) of polynomials of degree less than \( \deg(\Delta_{a}^{op}) \). One has the equality:

\[
(11.3.7) \quad \rank \left( \prod_{i=1}^{h} a_{1}^{[e-i+1]} \right)_{e, f \in \{0, 1, \ldots, h-1\}} = \deg(\Delta_{a}^{op}).
\]

iii) Let \( K = \mathbb{R} \) and \( \bar{a} \in (\mathbb{R}_{>0})^{h} \). Then, \( \Delta_{a}^{op} \) is divisible by \( 1-r^{h}s^{h} \). Conversely, let \( \Delta^{op} \) be a factor of \( 1-r^{h}s^{h} \) which is divisible by \( 1-r^{h}s^{h} \) for \( r \in \mathbb{R}_{>0} \) with the constant term \( 1. \) Then there exists a smooth non-empty semi-algebraic set \( C_{\Delta^{op}} \subset (\mathbb{R}_{>0})^{h} \) of dimension \( \deg(\Delta^{op}) - 1 \) such that \( \Delta^{op} = \Delta_{a}^{op} \) for all \( \bar{a} \in C_{\Delta^{op}}. \)

**Proof.** i) By the definitions (11.3.3) and (11.3.4), we have the relations:

\[
(11.3.8) \quad a_{1}^{[e]+1} s A_{[e]}^{[e]}(s) + (1-r^{h}s^{h}) = A_{[e]+1}^{[e]}(s)
\]

for \([e] \in \mathbb{Z}/h\mathbb{Z} \). This implies \( \gcd(A_{[e]}^{[e]}(s), 1-r^{h}s^{h}) \) and \( \gcd(A_{[e]}^{[e]+1}(s), 1-r^{h}s^{h}) \) for \([e] \in \mathbb{Z}/h\mathbb{Z} \) so that one concludes that all the elements \( \gcd(A_{[e]}^{[e]}(s), 1-r^{h}s^{h}) = \gcd(A_{[e]}^{[e]}(s), A_{[e]}^{[e]+1}(s)) \) for \([e] \in \mathbb{Z}/h\mathbb{Z} \) are the same up to a constant factor.
ii) Let us show that the images in $K[s]/(\Delta_{\text{op}})$ of the polynomials $A^{[e]}(s)/\delta_{\text{op}}(s)$ for $[e] \in \mathbb{Z}/h\mathbb{Z}$ span the entire space over $K$. Let $V$ be the space spanned by the images. The relation (11.3.8) implies that $V$ is closed under the multiplication of $s$. On the other hand, $A^{[e]}(s)/\delta_{\text{op}}(s)$ and $\Delta_{\text{op}}$ are relatively prime so that they generate 1 as a $K[s]$-module. That is, $V$ contains the class [1] of 1, and, hence, $V$ contains the whole $K[s]$·[1]. Since $\deg(A^{[e]}(s)/\delta_{\text{op}}(s)) < \deg(\Delta_{\text{op}})$, this means that the polynomials $A^{[e]}(s)/\delta_{\text{op}}(s)$ for $[e] \in \mathbb{Z}/h\mathbb{Z}$ span the space of polynomials of degree less than $\deg(\Delta_{\text{op}})$. In particular, one has $\text{rank}_K V = \deg(\Delta_{\text{op}})$.

By definition, $\text{rank}(\prod_{i=1}^{d} a_i^{[e_i-i+1]}c_i \in \{0,1,\ldots,h-1\})$ is equal to the rank of the space spanned by $A^{[e]}(s)$ for $[e] \in \mathbb{Z}/h\mathbb{Z}$, which is equal to the rank of the space spanned by $A^{[e]}(s)/\delta_{\text{op}}(s)$ for $[e] \in \mathbb{Z}/h\mathbb{Z}$ and is equal to $\deg(\Delta_{\text{op}})$.

iii) If $(1-rs) \not| \Delta_{\text{op}}$, then $1-rs \mid \delta_{\text{op}} | A^{[e]}(s)$ and $A^{[e]}(1/r) = 0$. This is impossible since all coefficients of $A^{[e]}$ and 1/r are positive. Conversely, let $\Delta_{\text{op}}$ be a factor of $1-r^h s^h$ which is divisible by $1-rh$, whose degree is $d>0$. Put $\mathbb{R}[s]_{d-1} := \{c(s) \in \mathbb{R}[s] \mid \deg(c(s)) = d-1, \ c(0) = 1\}$. Consider the set

$$\mathcal{C}_{\Delta_{\text{op}}} := \{c(s) \in \mathbb{R}[s]_{d-1} \mid \text{all coefficients of } c'(s) := c(s)\frac{1-r^h s^h}{\Delta_{\text{op}}} \text{ are positive}\}.$$ 

Since $\mathcal{C}_{\Delta_{\text{op}}}$ is defined by strict inequalities, it is an open subset of $\mathbb{R}[s]_{d-1}$. Further, it is non-empty since it contains $\Delta_{\text{op}}/(1-rs)$. For any $c(s) \in \mathcal{C}_{\Delta_{\text{op}}}$, we note that $\deg(c'(s)) = h-1$, and hence one can find a unique $\overline{\pi} \in (\mathbb{R}_{>0})^h$ satisfying $c'(s) = A^{[0]}(s)$ (11.3.2) and $\Delta_{\text{op}}$. By this correspondence $c(s) \mapsto \overline{\pi}$, we embed $\mathcal{C}_{\Delta_{\text{op}}}$ smoothly to a smooth semialgebraic subset of $(\mathbb{R}_{>0})^h$ of dimension $d-1$.

If $\overline{\pi}$ is the image of $c(s) \in \mathcal{C}_{\Delta_{\text{op}}}$, then $\delta_{\overline{\pi}} := \text{gcd}\{c'(s), 1-r^h s^h\}$ is divisible by $(1-r^h s^h)/\Delta_{\text{op}}$. That is, $\Delta_{\text{op}} := (1-r^h s^h)/\delta_{\overline{\pi}}$ is a factor of $\Delta_{\text{op}}$. This implies that the $c(s)$ is a point of the embedded image $C_{\Delta_{\text{op}}} \rightarrow \mathcal{C}_{\Delta_{\text{op}}}$ (defined by the multiplication of $\Delta_{\text{op}}$). Define the semialgebraic set $C_{\Delta_{\text{op}}} := \mathcal{C}_{\Delta_{\text{op}}} \cup \Delta \mathcal{C}_{\Delta'}$, where the index $\Delta'$ runs over all factors of $\Delta_{\text{op}}$ (over $\mathbb{R}$) which are not equal to $\Delta_{\text{op}}$ and are divisible by $1-rs$. Since $\dim_{\mathbb{R}}(\mathcal{C}_{\Delta}) = d-1 > \dim_{\mathbb{R}}(\mathcal{C}_{\Delta'})$ so that the difference $C_{\Delta}$ is non-empty.

Suppose the characteristic of the field $\mathbb{K}$ is equal to zero. Let $\bar{K}$ be the splitting field of $\Delta_{\text{op}}$ with the decomposition $\Delta_{\text{op}} = \prod_{i=1}^{d}(1-x_i s)$ in $\bar{K}$ for $d := \deg(\Delta_{\text{op}})$. Then, one has the partial fraction decomposition:

$$A^{[e]}(s)_{1-r^h s^h} = \sum_{i=1}^{d} \frac{\mu^{[e]}_i}{1-x_i s}$$

for $[e] \in \mathbb{Z}/h\mathbb{Z}$, where $\mu^{[e]}_i$ is a constant in $\bar{K}$ given by the residue:

$$\mu^{[e]}_i = \frac{A^{[e]}(s)(1-x_i s)}{1-r^h s^h} \bigg|_{s=(x_i)^{-1}} = \frac{1}{h} A^{[e]}(x_i^{-1}).$$
Here, one has the equivariance \( \sigma(\mu_x^{[e]}) = \mu_{\sigma(x)}^{[e]} \) with respect to the action of \( \sigma \in \text{Gal}(\overline{K}, K) \). The matrix \( (\mu_x^{[e]})_{[e],x} \) is of maximal rank \( d = \deg(\Delta^\text{op}_P) \).

**Remark.** The index \( x_i \) in (11.3.10) may run over all roots \( x \) of the equation \( x^h - r^h = 0 \). However, if \( x \) is not a root of \( \Delta^\text{op}_P \) (i.e. \( \Delta^\text{op}_P(x^{-1}) \neq 0 \)), then \( \mu_x^{[e]} = 0 \).

We return to the series \( P(t) \) (11.2.1) with positive radius \( r > 0 \) of convergence. If \( P(t) \) is finite rationally accumulating of period \( h \) and \( a_1^{[e]} := \iota(a^{[e]}) \) for \( [e] \in \mathbb{Z}/h\mathbb{Z} \) (recall (11.3.1)), then \( \Delta^\text{op}_P(s) \) depends only on \( P \) but not on the choice of the period \( h \). Therefore, we shall denote it by \( \Delta^\text{op}_P(s) \). The previous Assertion ii) says that we have the \( \mathbb{R} \)-isomorphism:

\[
(11.3.11) \quad \overline{\mathbb{R}}\Omega(P) \simeq \mathbb{R}[s]/(\Delta^\text{op}_P(s)), \quad a^{[e]} \mapsto \Delta^\text{op}_P \cdot a^{[e]} \mod \Delta^\text{op}_P.
\]

Since the action of \( \tau \) is invertible, we define an endomorphism \( \sigma \) on \( \overline{\mathbb{R}}\Omega(P) \) by

\[
(11.3.12) \quad \sigma(a^{[e]}) := \tau^{-1}(a^{[e]}) = \frac{1}{a_1^{[e]} + 1} a^{[e+1]}.
\]

The action of \( \sigma \) on the LHS and the multiplication of \( s \) on the RHS are equivariant with respect to the isomorphism (11.3.11). Hence, the linear dependence relations among the generators \( a^{[e]} \) \( ([e] \in \mathbb{Z}/h\mathbb{Z}) \) are obtained by the relations \( \Delta^\text{op}_P(\sigma)a^{[e]} = 0 \) for \( [e] \in \mathbb{Z}/h\mathbb{Z} \). However, one should note that the \( \sigma \)-action on \( \overline{\mathbb{R}}\Omega(P) \) is not the same as the multiplication of \( s \) as the subspace of \( \mathbb{R}[s] \).

### 11.4 Duality between \( \Delta^\text{op}_P(s) \) and \( \Delta_P^\text{top}(t) \)

Assuming that \( P(t) \) extends to a meromorphic function in a neighborhood of the closure of its convergent disc, we show a duality between the poles of opposite sequences of \( P(t) \) and the poles of \( P(t) \) on its convergent circle.

**Definition.** For a positive real number \( r \), let us denote by \( \mathbb{C}\{t\}_r \) the space consisting of complex powers series \( P(t) \) such that i) \( P(t) \) converges (at least) on the open disc centered at 0 of radius \( r \), and ii) \( P(t) \) analytically continues to a meromorphic function on a disc centered at 0 of radius \( r \). Let \( \Delta_P(t) \) be the monic polynomial in \( t \) of minimal degree such that \( \Delta_P(t)P(t) \) is holomorphic in a neighborhood of the circle \( |t|=r \). Put \( \Delta_P(t) = \prod_{i=1}^{N}(t - x_i)^{d_i} \) where \( x_i \) \( (i=1, \ldots, N, N \in \mathbb{Z}_{\geq 0}) \) are mutually distinct complex numbers with \( |x_i| = r \) and \( d_i \in \mathbb{Z}_{\geq 0} \) \( (i=1, \ldots, N) \). Define the equation for the set of poles of highest order:

\[
(11.4.1) \quad \Delta_P^\text{top}(t) := \prod_{i:d_i = d_m}(t - x_i) \quad \text{where} \quad d_m := \max\{d_i\}_{i=1}^{N}.
\]

**Definition.** Define an action \( T_U \) on \( \mathbb{C}[t] \) for a rational set \( U \) of \( \mathbb{Z}_{\geq 0} \) by

\[
(11.4.2) \quad P = \sum_{n \in \mathbb{Z}_{\geq 0}} \gamma_n t^n \mapsto T_U P := \sum_{n \in U} \gamma_n t^n.
\]
One may regard $T_U P$ as a product of $P$ with the function $U(t)$ in the sense of Hadamard \[11\]. The radius of convergence of $T_U P$ is not less than that of $P$.

**Fact 1.** The action of $T_U$ preserves the space $\mathbb{C}\{t\}_r$ for any $r \in \mathbb{R}_{>0}$.

**Proof.** Let us expand the meromorphic function $P(t)$ into partial fractions

$$ P(t) = \sum_{i=1}^{N} \sum_{j=1}^{d_i} \frac{c_{i,j}}{(t-x_i)j} + Q(t), $$

where the coefficients $c_{i,j}$ of the principal part $\sum_{i=1}^{N} \sum_{j=0}^{d_i} \frac{c_{i,j}}{(t-x_i)^j}$ of $P(t)$ are constants with $c_{i,d_i} \neq 0$ for all $i$, and $Q(t)$ is a holomorphic function on a disc of radius $r > 0$. Then, $T_U P = \sum_{i,j} T_U \frac{c_{i,j}}{(t-x_i)^j} + T_U Q$ where $T_U Q$ is a holomorphic function on a disc of radius $> r$. It is sufficient to show that, for any standard rational set $U^{[r]} := \{n \in \mathbb{Z}_{\geq 0} \mid n \equiv [c] \mod{h}\}$ of period $h \in \mathbb{Z}_{>0}$ and $[c] \in \mathbb{Z}/h\mathbb{Z}$, one has $T_U^{[c]} \frac{1}{(t-x_i)^j} = \frac{B_{i,j}(t)}{(t^n-x_i^k)^j}$ where $B_{i,j}(t)$ is a polynomial in $t$. We calculate this explicitly as follows. For the purpose, we claim a “semi-commutativity” $T_U^{[c]} \frac{d}{dt} = \frac{d}{dt} T_U^{[c+1]}$ (proof is trivial and is omitted). Then,

$$ T_U^{[c]} \frac{1}{(t-x_i)^j} = T_U^{[c]} \frac{(-1)^{j-1}}{(j-1)!} \left( \frac{d}{dt} \frac{1}{t-x_i} \right)^{j-1} \frac{1}{t-x_i} \left( \frac{d}{dt} \frac{1}{t-x_i} \right) \frac{1}{t^n-x_i^k} = (-1)^{j-1} \frac{1}{(j-1)!} \left( \frac{d}{dt} \frac{1}{t-x_i} \right)^{j-1} \frac{t^f}{t^n-x_i^k} $$

where $f = e+j-1-h[(e+j-1)/h]$. This gives the required result. \[ \square \]

The following is the goal of the present subsection.

**Theorem 5. (Duality)** Suppose $P(t)$ \[(11.2.1)\] belongs in $\mathbb{C}\{t\}_r$ for $r = \text{the radius of convergence of } P$, and is finite accumulating. Then, we have

\begin{align*}
(11.4.3) & \quad t^{\deg(\Delta_P^t)} \Delta_P^t(t^{-1}) = \Delta_P^{t_\text{top}}(t), \\
(11.4.4) & \quad \text{rank}(\text{IM}(P)) = \deg(\Delta_P^t) = \deg(\Delta_P^{t_\text{top}}).
\end{align*}

**Proof.** We first show some special case followed by the general case.

**Fact 2.** If $P(t)$, above, is simple accumulating (i.e. $\#\Omega(P) = 1$), then $\Delta_P^{t_\text{top}} = t-r$.

**Proof.** That $P(t)$ is simply accumulating means $\lim_{n \to \infty} \frac{n}{\gamma_n} = r$ and hence, for any small $\varepsilon > 0$, there exists $c > 0$ such that $\gamma_n \geq c(r+\varepsilon)^{-n}$ for $n \in \mathbb{Z}_{\geq 0}$. Let $\delta_n$ be the $n$th Taylor coefficients of $Q$ in the splitting $\ast$. By assumption on $Q$, there exists $r' > r$ and a constant $c'>0$ such that $\delta_n \leq c'r'^{-n}$ for $n \in \mathbb{Z}_{\geq 0}$. Therefore, choosing $\varepsilon$ such that $r+\varepsilon < r'$, we have $\delta_n/\gamma_n \to 0$. Since the $n$th Taylor coefficient of the principal part of the splitting $\ast$ of $P$ is given by $\gamma_n - \delta_n$, the principal part, say $P'$, is also simply accumulating. That is, $X_n(P') = \sum_{k=0}^{n} \frac{\sum_{i=1}^{N} \sum_{j=1}^{d_i} c_{i,j} \frac{1}{x_i^{n-k}} \frac{1}{(n-k)!}}{\sum_{i=1}^{N} \sum_{j=1}^{d_i} c_{i,j} \frac{1}{x_i^{n-j}} \frac{1}{(n-j)!}} s^k$ converges to $\frac{1}{1-rs}$...
\[ \sum_{k=0}^{\infty} r^k s^k. \]
Under this setting, we want to show that if \( c_{i,d,m} \neq 0 \) then \( x_i = r \).
For convenience in the proof, we may assume \( r = 1 \) and hence \( |x_i| = 1 \) for all \( i \).

Consider the sequence \( v_n := \sum_{i=1}^{N} c_{i,d,m} x_i^{-n} \) in \( n \in \mathbb{Z}_{\geq 0} \). Since \( |v_n| \leq \sum |c_{i,d,m}| \) is bounded, the sequence accumulates to a compact set in \( \mathbb{C} \). If the sequence has a unique accumulating value, say \( v_0 \) then the result is already true.

((Proof). Consider the mean sequence: \( \{(\sum_{n=0}^{M-1} v_n)/M\}_{M \in \mathbb{Z}_{\geq 0}} \). On one side, it converges to \( v_0 \) by the assumption. On the other side, \( \sum_{i=1}^{N} c_{i,d,m} \sum_{n=0}^{M-1} x_i^{-n-1} \)
converges to \( c_{1,d,m} \), where we assume \( x_1 = 1 \). That is, the sequence \( v'_n := \sum_{i=1}^{N} c_{i,d,m} x_i^{-n-1} \) converges to \( 0 \). For a fixed \( n_0 \in \mathbb{Z}_{\geq 0} \), consider the relations:
\[
v'_{n+k} = \sum_{i=1}^{N} c_{i,d,m} x_i^{-n-k} \]
for \( k = 1, \ldots, N-1 \). Regarding \( c_{i,d,m} x_i^{-n_0} \) \((i = 2, \cdots, N)\) as the unknown, we can solve the linear equation by a use of the van der Monde determinant for the matrix \((x_i^{-k+1})_{i=2, \cdots, N, k=1, \cdots, N-1}\). So, we obtain a linear approximation: \(|c_{i,d,m} x_i^{-n_0}| \leq c \cdot \max\{|v'_{n+k}|\}_{k=1}^{N-1} \) \((i = 2, \cdots, N)\) for a constant \( c > 0 \) which is independent of \( n_0 \). The RHS tends to zero as \( n_0 \to \infty \), whereas the LHS is unchanged. This implies \(|c_{i,d,m}| = 0 \) \((i = 2, \cdots, N)\).

Next, consider the case that the sequence \( v_n \) has more than two accumulating values. Suppose the subsequence \( \{v_{n_m}\}_{m \in \mathbb{Z}_{\geq 0}} \) converges to a non-zero value, say \( c \). Recall the assumption that the sequence \( \gamma_{n-1}/\gamma_n \) converges to \( 1 \). So, the subsequence \( \gamma_{n_m}^{-1} = \frac{v_{n_m-1} + \text{lower terms}}{v_{n_m} + \text{lower terms}} \) should also converges to \( 1 \) as \( m \to \infty \). In the denominator, the first term tends to \( c \neq 0 \) and the second term tends to \( 0 \). Similarly, in the numerator, the second term tends to \( 0 \). This implies that the first term in the numerator converges to \( c \). Repeating the same argument, we see that for any \( k \in \mathbb{Z}_{\geq 0} \), the subsequence \( \{v_{n_m-k}\}_{m \in \mathbb{Z}_{\geq 0}} \) converges to the same \( c \). Then, for each fixed \( M \in \mathbb{Z}_{>0} \), the average sequence \( \{\sum_{k=0}^{M-1} v_{n_m-k}/M\}_{m \in \mathbb{Z}_{\geq 0}} \) converges to \( c \), whereas, for sufficiently large \( M \), the values are close to \( c_{1,d,m} \). This implies \( c = c_{1,d,m} \). In other words, the sequences \( \{v'_{n_m-k}\}_{m \in \mathbb{Z}_{\geq 0}} \) for any \( k \geq 0 \) converge to \( 0 \). Then, an argument as in the previous case implies \(|c_{i,d,m}| = 0 \) \((i = 2, \cdots, N)\).

This is the end of the proof of Fact 2. \( \Box \)

We return to the general case, where \( P \) is finite rational accumulating of period \( h \). For the standard partition \( \{U[e] \mid [e] \in \mathbb{Z}/h\mathbb{Z}\} \), put \( T[e] := T_{U[e]} \). They decompose the unity: \( \sum_{[e] \in \mathbb{Z}/h\mathbb{Z}} T[e] = 1 \). By the assumption, for each \( 0 \leq f < h \), the series \( T^{[f]} P = t \sum_{m=0}^{\infty} \gamma t^{f+m} \tau^m \), considered as a series in \( \tau = t^h \), is simple accumulating. Then Fact 2 implies that the highest order polynomials are only at solutions \( x \) of the equation \( t^h r^h = 0 \). In view of the fact that the highest order of poles in \( t \) on the circle \( |t| = r \) of \( T^{[f]} P \) cannot exceed that of \( P \) (recall the explicit expression in Fact 1) and the fact \( P = \sum_{[e] \in \mathbb{Z}/h\mathbb{Z}} T[e] P \), the highest order polynomials are also only at solutions \( x \) of the equation \( t^h - r^h = 0 \). That
is, $\Delta_{P}^{top}(t)$ is a factor of $t^h - r^h$. For $0 \leq e, f < h$ and a root $x$ of the equation $t^h - r^h$, we evaluate (10.6.4) for $\{n_m = e + mh\}_{m=0}^{\infty}$ and $\{n_m = f + mh\}_{m=0}^{\infty}$

$$T[f|P(t)|_{t=x} = x^{f-e} \sum_{m=0}^{\infty} \gamma(t + mh)^m \bigg|_{t=x} = x^{f-e} \lim_{m \to \infty} \frac{\gamma(t + mh)}{\gamma(r + mh)}$$

Then, a similar argument to that for (11.3.1) shows the formula

$$(11.4.5)\quad \frac{T[e|P(t)|_{t=x} = \begin{cases} x^{f-e}a_1^{[f]}a_1^{[f-1]}\cdots a_1^{[\epsilon+1]} & \text{if } e < f \vspace{0.1cm} \\ 1 & \text{if } e = f \\ x^{f-e}a_1^{[\epsilon]}a_1^{[\epsilon-1]}\cdots a_1^{[f+1]} & \text{if } e > f. \end{cases}$$

This implies that the order of poles of $T[e|P(t)$ a solution $x$ of the equation $t^h - r^h$ is independent of $[e] \in \mathbb{Z}/h\mathbb{Z}$. On the other hand, (11.4.5) implies

$$(11.4.6)\quad \frac{T[e|P(t)|_{t=x} = \frac{1}{A[e](x^{-1})}. \vspace{0.1cm}$$

(recall the $A[e](s)$ (11.3.2)). Let $x$ be a solution of $t^h - r^h = 0$ but $\Delta_{P}^{op}(x^{-1}) \neq 0$. Then $\delta_n(x^{-1}) = 0$ (see (11.3.6)) and $A[e](x^{-1}) = 0$ for $[e] \in \mathbb{Z}/h\mathbb{Z}$ (see Assertion i)). That is, $\frac{T[e|P(t)} has a pole at $t = x$. This implies that the pole of $P(t)$ at $t = x$ is of order $< d_m$ (otherwise, the pole at $t = x$ of $T[e|P$ is of order $d_m$ at most and can be canceled by dividing by $P$). That is, $\Delta_P^{op}(t) \mid t^d\Delta_P^{op}(t^{-1})$.

**Fact 3.** Let $P(t)$ (11.2.1) belong to $\mathbb{C}\{t\}_r$ and be finitely accumulating. Then

i) There exists a positive constant $c$ such that $\gamma_n \geq c n^{-n} d_m^{-1}$ for $n \gg 0$.

ii) $t^d\Delta_P^{op}(t^{-1}) \mid \Delta_P^{top}(t)$.

**Proof.** i) Consider the Taylor expansion of the function $s(x)$. Using notation $v_n$ in Fact 2., we have $\gamma_n = -v_n e^{-n-1}((d_m)^{-1}) +$ terms coming from poles of order $< d_m$ and terms coming from $Q(t)$, where $v_n = \sum_{i=1} \alpha_i d_m (x_i/r)^{-n-1}$ depends only on $n$ mod $h$ since $x_i$ is the root of the equation $t^h - r^h = 0$. Not all of these are zero (otherwise $c_i d_m = 0$ for all $i$). Let us show that none of the $v_n$ are zero. Suppose the contrary and $v_n \neq 0$. Then, one observes easily $\lim_{m \to \infty} \frac{\gamma(t + mh)}{\gamma(r + mh)} = 0$. This contradicts the assumption $\Omega_1(P) \subset [u, v]$ (positivity of initials).

ii) By definition, the fractional expansion of $\Delta_P^{top}(t)P(t)$ has poles of order at most $d_m - 1$. This means that its $(n-k)\text{th}$ Taylor coefficient:

**(**) $\gamma_{n-k} \cdot \alpha_l + \gamma_{n-k-1} \cdot \alpha_{l-1} + \cdots + \gamma_{n-k-1} \cdot 1 \sim o((n-k)d_m^{-1}r^{-(n-k)})$

as $n \to \infty$ ($k, n \in \mathbb{Z}_{\geq 0}$) (here, $\Delta_P^{op}(t) = t^l + \alpha_1 t^{l-1} + \cdots + \alpha_l$. Let $\sum k a_k s^k \in \Omega(P)$ be the limit of a subsequence $\{X_{n_m}(P)\}_{m \in \mathbb{Z}_{\geq 0}}$ (11.2.1). Divide ** by $\gamma_n$. Then, using the part i), one has

$$a_k \alpha_l + a_{k+1} \alpha_{l-1} + \cdots + a_{k+l} = 0$$
for any \( k \geq 0 \). Thus \( s^l \Delta_P^{\text{op}}(1/s)a(s) \) is a polynomial in \( s \) of degree \( < l \). Thus the denominator \( \Delta_P^{\text{op}}(s) \) of \( a(s) \) divides \( s^l \Delta_P^{\text{op}}(s^{-1}) \). So, ii) is shown. \( \square \)

We showed (11.4.3). (11.4.4) follows from (11.3.11) and (11.4.3). \( \square \)

**Example.** Recall Machi’s example 11.2 for the modular group \( \Gamma \). We have

\[
T_eP(t) = \sum_{k=0}^{\infty} \# \Gamma_{2k} t^{2k} = \frac{1+5t^2}{(1-t^2)(1-t^4)}, \quad T_oP(t) = \sum_{k=0}^{\infty} \# \Gamma_{2k+1} t^{2k+1} = \frac{2t(2+t^2)}{(1-2t)(1-t^2)},
\]

Then the transformation matrix is given by

\[
\begin{bmatrix}
T_eP(t) & T_oP(t) \\
T_oP(t) & T_eP(t)
\end{bmatrix} = \begin{bmatrix}
\frac{1+5t^2}{(1+t)^2(1-2t)} & \frac{2(2+t^2)}{1+t^2} \\
\frac{2(2+t^2)}{1+t^2} & \frac{1+5t^2}{(1+t)^2(1-2t)}
\end{bmatrix} = \begin{bmatrix}
7(5\sqrt{2}-7) & 5(10-7\sqrt{2}) \\
7(5\sqrt{2}+7) & 5(10+7\sqrt{2})
\end{bmatrix}
\]

whose determinant is equal to \( \frac{5+7}{\sqrt{2}} \neq 0 \).

### 11.5 The residual representation of trace elements

As the goal of the present paper, under further assumptions i) \( \#(\Omega(\Gamma, G)) < \infty \) and ii) \( P_{\Gamma, G} \in \mathbb{C}\{t\}_{r_{\Gamma, G}} \), we show a trace formula, which states that the sum of the limit elements in a orbit of the inertia group is expressed by a linear combination of the proportions of residues of the Poincare series \( P_{\Gamma, G}(t) \) and \( P_{\Gamma, G,M}(t) \) at the poles on the circle of their convergent radius, where the coefficients are given by special values of the opposite polynomials \( A^{[e]}(s) \).

We first show the following basic consequence of the finiteness \( \#(\Omega(\Gamma, G)) < \infty \).

**Lemma.** Let \((\Gamma, G)\) be the pair of a monoid and its finite generating system, which satisfies Assumption 1 but not necessarily 2. If the limit space \( \Omega(\Gamma, G) \) is finite, then it is finite rationally accumulating with respect to the standard partition \( U_h \) of \( \mathbb{Z}_{\geq 0} \) for some \( h > 0 \), and \( \tilde{\tau}_\Omega \) acts transitively on \( \Omega(\Gamma, G) \) of period \( h \). In particular, \( \tilde{\tau}_\Omega \) is invertible.

**Proof.** Recall the action \( \tilde{\tau}_\Omega \) on \( \Omega(\Gamma, G) \) (Lemma in 11.2). Then, finiteness of \( \Omega(\Gamma, G) \) implies that there exists an element \( \omega \in \Omega(\Gamma, G) \) and an integer \( h \in \mathbb{Z}_{\geq 0} \) such that \( (\tilde{\tau}_\Omega)^h \omega = \omega \) and \( (\tilde{\tau}_\Omega)^{h'} \omega \neq \omega \) for \( 0 < h' < h \). Consider the set \( U_\omega := \{ n \in \mathbb{Z}_{\geq 0} | \frac{M(\Gamma_n)}{\# \Omega_n} \in \mathcal{V}_{\omega} \} \) (here, \( \mathcal{V}_{\omega} \) is an open neighborhood of \( \omega \) in \( L_{\mathbb{R},\infty} \) such that \( \bigcup_{\omega} \cap \Omega(\Gamma, G) = \{ \omega \} \)). Then, the periodicity of the action of \( \tilde{\tau}_\Omega \) on \( \omega \) implies (using an argument similar to that found in the proof of 11.2 Lemma, replacing \( a \in \Omega(P) \) by \( \omega \in \Omega(\Gamma, G) \) and \( h \) by \( \tilde{h} \), respectively) that \( U_\omega \) is, up to a finite number of elements, equal to a rational set \( U^{[e]} \) for some \( [e] \in \mathbb{Z}/h\mathbb{Z} \), and the following equality holds:

\[
\Omega(\Gamma, G) = \{ \omega, \tilde{\tau}_\Omega \omega, \cdots, (\tilde{\tau}_\Omega)^{h-1} \omega \}.
\]

This implies the finite rationality of \( \Omega(\Gamma, G) \) and the periodicity of \( \tilde{\tau}_\Omega \). \( \square \)
Let \( \Omega(\Gamma, G) \) be finite rationally accumulating of period \( \tilde{h} \), which consists of

\[
\omega_{\Gamma,G}^{[\tilde{e}]} := \lim_{m \to \infty} \frac{M(\Gamma, e + mh)}{m!}
\]

for \( [\tilde{e}] \in \mathbb{Z}/\tilde{h}\mathbb{Z} \). Then, \( \Omega(\Gamma, G) \) is also finite rationally accumulating of period \( h \) such that \( h|\tilde{h} \) (c.f. 11.2 Lemma), since the sequence \( \{ \pi \left( \frac{M(\Gamma_n)}{n!} \right) = X_n(\Gamma,G) \}_{n \in U[\tilde{e}]} \) for the rational set \( U[\tilde{e}] := \{ n \in \mathbb{Z}_{\geq 0} \mid n \text{ mod } \tilde{h} \equiv [\tilde{e}] \} \) for any \( [\tilde{e}] \in \mathbb{Z}/\tilde{h}\mathbb{Z} \) is convergent to \( \pi(\omega_{\Gamma,G}^{[\tilde{e}]}). \)

Let \( \tilde{h}_{\Gamma,G} \) and \( h_{\Gamma,G} \) be the minimal period of \( \Omega(\Gamma, G) \) and \( \Omega(\Gamma, G) \), respectively. Then \( \pi \) is equivariant under the \( \tilde{\tau}_G \)-action on \( \Omega(\Gamma, G) \) and the \( \tau_G \)-action on \( \Omega(\Gamma, G) \) so that the subgroup \( h_{\Gamma,G}\mathbb{Z}/\tilde{h}_{\Gamma,G}\mathbb{Z} \) of \( \mathbb{Z}/\tilde{h}_{\Gamma,G}\mathbb{Z} \) is isomorphic to \( (\tilde{\tau}_G) \), called the inertia subgroup, acts simply and transitively on the fibers of \( \pi \). That is, \( \Omega(\Gamma, G)/(h_{\Gamma,G}Z/\tilde{h}_{\Gamma,G}Z) \sim \Omega(\Gamma, G) \). We call \( m_{\Gamma,G} := \tilde{h}_{\Gamma,G}/h_{\Gamma,G} \) the inertia of \( (\Gamma, G) \) so that the inertia subgroup is isomorphic to \( \mathbb{Z}/m_{\Gamma,G}\mathbb{Z} \).

**Definition.** The trace element for \( [\tilde{e}] \in \mathbb{Z}/h_{\Gamma,G}\mathbb{Z} \) is the sum of the elements in the fiber \( \pi^{-1}_G([\tilde{e}]) \) (=an orbit of the inertia group \( h_{\Gamma,G}\mathbb{Z}/\tilde{h}_{\Gamma,G}\mathbb{Z} \)):

\[
\text{Trace}^{[\tilde{e}]} \Omega(\Gamma, G) := \sum_{[\tilde{e}] \in \mathbb{Z}/h_{\Gamma,G}\mathbb{Z}} [\tilde{e}] \omega_{\Gamma,G}^{[\tilde{e}]} = \sum_{i=1}^{m_{\Gamma,G}} \omega_{\Gamma,G}^{[\tilde{e}]+ih_{\Gamma,G}}
\]

which belongs to the space \( \mathbb{R}\Omega(\Gamma, G) \).

The periodicity of \( \tilde{\tau}_G \) implies the invertibility of \( \tilde{\tau} \) (11.2.14). As its consequence, let us introduce a \( \tilde{\sigma} \)-action on the module \( \mathbb{R}\Omega(\Gamma, G) \).

**Definition.** For any \( [\tilde{e}] \in \mathbb{Z}/h_{\Gamma,G}\mathbb{Z} \), put \( [\tilde{e}] \equiv [\tilde{e}] \mod h_{\Gamma,G} \) and define

\[
\tilde{\sigma}(\omega_{\Gamma,G}^{[\tilde{e}]}) := \tilde{\tau}^{-1}(\omega_{\Gamma,G}^{[\tilde{e}]}) = \frac{1}{a_1^{[\tilde{e}]+1}} \omega_{\Gamma,G}^{[\tilde{e}]+1}.
\]

The endomorphism \( \tilde{\sigma} \) is semi-simple since one has \( \tilde{\sigma}h_{\Gamma,G} = h_{\Gamma,G} \tilde{\sigma} \text{id}_{\mathbb{R}\Omega(\Gamma, G)} \) (c.f. (11.3.3)). The \( \mathbb{R} \)-linear map \( \tilde{\tau} \) (11.2.15) is equivariant with respect to the endomorphisms \( \tilde{\sigma} \) and \( \sigma \) (11.3.12). By the definition, we see that the \( \tilde{\sigma} \)-action brings, up to a constant factor, a trace element to the other trace element

\[
\tilde{\sigma} \left( \text{Trace}^{[\tilde{e}]} \Omega(\Gamma, G) \right) := \frac{1}{a_1^{[\tilde{e}]+n}} \text{Trace}^{[\tilde{e}]+n} \Omega(\Gamma, G)
\]

for all \( [\tilde{e}] \in \mathbb{Z}/h_{\Gamma,G}\mathbb{Z} \). In view of (11.3.3), this, in particular, implies

\[
(1 - (r_{\Gamma,G} \tilde{\sigma})^n) \left( \text{Trace}^{[\tilde{e}]} \Omega(\Gamma, G) \right) = 0.
\]

After the results of 11.3 and 11.4, the next theorem is now straightforward.

**Theorem. 6.** Let \((\Gamma, G)\) be a pair of a monoid and its finite generating system with \( 1 \notin G \), satisfying Assumptions 1 and 2. Suppose i) \( \Omega(\Gamma, G) \) is finite, and ii) \( P_{\Gamma,G} \in \mathbb{C}\{1\}_{r_{\Gamma,G}} \). Let \( h_{\Gamma,G} \) and \( h_{\Gamma,G} \) be the minimal period of
\[ \Omega(\Gamma, G) \text{ and } \Omega(P_{\Gamma,G}), \text{ respectively, and put } \tilde{m}_{\Gamma,G} := \tilde{h}_{\Gamma,G}/h_{\Gamma,G}. \text{ Then, for any } [c] \in \mathbb{Z}/h_{\Gamma,G}\mathbb{Z}, \text{ the following equality holds.} \]

\[ h_{\Gamma,G} \text{Trace}^{[c]} \Omega_{\Gamma,G} - \left( \sum_{x^{-1} \in V(\delta_{P_{\Gamma,G}})} \Delta^\text{top}_{P_{\Gamma,G}}(\tilde{\sigma}) \right) \Delta^\text{top}_{P_{\Gamma,G}}(\tilde{\sigma}) \text{Trace}^{[c]} \Omega_{\Gamma,G} \]

\[ (11.5.6) \]

where we put \( \delta_{P_{\Gamma,G}}(\tilde{\sigma}) := (1 - r_{h_{\Gamma,G}}^\text{top} \tilde{\sigma})/\Delta^\text{top}_{P_{\Gamma,G}}(\tilde{\sigma}) \) (c.f. (11.3.6)) and we denote by \( V(P) \) the set of zero loci of the polynomial \( P \).

**Proof.** Let us call \( \left. \left. \frac{P_{\Gamma,G}(M(t))}{P_{\Gamma,G}(t)} \right|_{t=x} \right. \) in RHS of the formula (11.5.6) a residue element, since it is a proportion of the residues of \( P_{\Gamma,G}(M(t)) \) and \( P_{\Gamma,G}(t) \) at the point \( t = x \). Let us, first, express the residue element by a sum of trace elements. For the purpose, consider the decomposition of unity:

\[ * \quad \frac{P_{\Gamma,G}(M(t))}{P_{\Gamma,G}(t)} = \sum_{[f] \in \mathbb{Z}/h_{\Gamma,G}\mathbb{Z}} \frac{T^{[f]} P_{\Gamma,G}(t)}{P_{\Gamma,G}(t)} \cdot \frac{T^{[f]} P_{\Gamma,G}(M(t))}{T^{[f]} P_{\Gamma,G}(t)}, \]

where \( T^{[f]} = T_{U^{[f]}} \) (11.4.2) is the action of the rational set \( U^{[f]} \) of the standard subdivision for \( \Omega(\Gamma, G) \) so that \( \sum_{f \in \mathbb{Z}/h_{\Gamma,G}\mathbb{Z}} T^{[f]} = 1 \). Let \( x \) be a root of \( \Delta^\text{top}_{P_{\Gamma,G}}(t) = 0 \), and consider the evaluation of both sides of \( * \) at \( t = x \). The LHS gives, by definition, the residue element at \( x \). By a slight generalization of the formula (11.3.6), the first factor in the RHS is given by \( 1/A^{[f]}(x^{-1}) = 1/(m_{\Gamma,G} A^{[f]}(x^{-1})) \) (note that \( A^{[f]}(x^{-1}) \neq 0 \) since \( \delta_{P_{\Gamma,G}}(x^{-1}) \neq 0 \), where \([f] := [f] \) mod \( h_{\Gamma,G} \). The second factor in RHS is

\[ \sum_{m=0}^{\infty} \mathcal{M}(\Gamma_{f+ih_{\Gamma,G}}) \left| \frac{\Gamma_{f+ih_{\Gamma,G}}}{f+ih_{\Gamma,G}} \right|_{t=x} = \sum_{m=0}^{\infty} \# \Gamma_{f+ih_{\Gamma,G}} \left| \frac{\Gamma_{f+ih_{\Gamma,G}}}{f+ih_{\Gamma,G}} \right|_{t=i} \left. \frac{\mathcal{M}(\Gamma_{f+ih_{\Gamma,G}})}{\# \Gamma_{f+ih_{\Gamma,G}}} \right|_{m=0} \]

where, in the RHS, \( i := i_{h_{\Gamma,G}} \) is the new variable and \( r_{h_{\Gamma,G}} = x_{h_{\Gamma,G}} \) is the common singular point of the two power series (the numerator and the denominator) in \( i \) at the crossing of the positive real axis and the circle of the convergent radius (c.f. 10.6 Lemma i)). Then, since the coefficients of the series are non-negative, this proportion of the residue value is equal to the limit of the proportion of the coefficients of the series (c.f. (10.6.4)) \( \lim_{m \to \infty} \left. \frac{\mathcal{M}(\Gamma_{f+ih_{\Gamma,G}})}{\# \Gamma_{f+ih_{\Gamma,G}}} \right|_{m=0} \)

but the limit element \( \omega^{[f]}_{\Gamma,G} \) (15.5.1). Put \( \bar{f} = f + ih_{\Gamma,G} \) for \( 0 \leq f < h_{\Gamma,G} \) and \( 0 \leq i < m_{\Gamma,G} \). Then the RHS turns into

\[ \frac{P_{\Gamma,G}(M(t))}{P_{\Gamma,G}(t)} \right|_{t=x} = \frac{1}{m_{\Gamma,G}} \sum_{[f] \in \mathbb{Z}/h_{\Gamma,G}\mathbb{Z}} \frac{1}{A^{[f]}(x^{-1})} \sum_{i=0}^{m_{\Gamma,G} - 1} \omega^{[f+ih_{\Gamma,G}]}_{\Gamma,G} \]

where the second sum in the RHS gives the trace \( \text{Trace}^{[f]} \Omega(\Gamma, G) \). That is,

\[ (11.5.7) \quad \left. \frac{P_{\Gamma,G}(M(t))}{P_{\Gamma,G}(t)} \right|_{t=x} = \frac{1}{m_{\Gamma,G}} \sum_{[f] \in \mathbb{Z}/h_{\Gamma,G}\mathbb{Z}} \frac{1}{A^{[f]}(x^{-1})} \text{Trace}^{[f]} \Omega(\Gamma, G). \]
For a fixed $[e] \in \mathbb{Z}/h_{\Gamma,G} \mathbb{Z}$, we multiply $A^e(x^{-1})$ to both sides of (11.5.7), and sum over the index $x$ running over the set $V(\Delta_{P_{\Gamma,G}^{top}})$ of all roots of $\Delta_{P_{\Gamma,G}^{top}}(t) = 0$, whose LHS is equal to the RHS of (11.5.6). Using (11.4.6), one observes that $A^e(x^{-1})$ is equal to the LHS of (11.4.5). Replace the summation index $"f]\in \mathbb{Z}/h_{\Gamma,G} \mathbb{Z}"$ in (11.5.7) by $"e+i]"$ for $i = 0, \ldots, h_{\Gamma,G} - 1$ for fixed $[e]$. Using the first line of RHS of (11.4.5) and $i$th repeated applications of (11.5.4), the sum in RHS turns out to

$$\frac{1}{m_{\Gamma,G}} \sum_{x \in V(\Delta_{P_{\Gamma,G}^{top}})} \sum_{i=0}^{h_{\Gamma,G}-1} \frac{A^e(x^{-1})}{A^{e+i}(x^{-1})} \text{Trace}^{e+i} \Omega_{\Gamma,G}$$

$$= \frac{1}{m_{\Gamma,G}} \sum_{x \in V(\Delta_{P_{\Gamma,G}^{top}})} \sum_{i=0}^{h_{\Gamma,G}-1} x^i \text{Trace}^{e+i} \Omega_{\Gamma,G}$$

Here, we note that the sum $\sum_{i=0}^{h_{\Gamma,G}-1} x^i \sigma^i$ is expressed as $\frac{1- (r_{\Gamma,G} \sigma)^{h_{\Gamma,G}}}{1 - x \sigma}$ and that $x \in V(\Delta_{P_{\Gamma,G}^{top}})$ is equivalent to $x^{-1} \in V(\Delta_{P_{\Gamma,G}^{op}})$ due to the duality (11.4.3). We further note that an identity:

$$\sum_{x^{-1} \in V(1-(r_{\Gamma,G} s)^{h_{\Gamma,G}})} = h_{\Gamma,G}$$

holds (in the polynomial ring of $s$). Therefore, recalling (11.3.6)

$$\delta_{P_{\Gamma,G}}(s) \cdot \Delta_{P_{\Gamma,G}^{op}}(s) = 1 - (r_{\Gamma,G} s)^{h_{\Gamma,G}}$$

we calculate further the sum as follows.

$$\frac{1}{m_{\Gamma,G}} \left( \sum_{x^{-1} \in V(\Delta_{P_{\Gamma,G}^{op}})} \frac{1- (r_{\Gamma,G} \sigma \bar{\sigma})^{h_{\Gamma,G}}}{1 - x \sigma} \right) \text{Trace}^{[e]} \Omega_{\Gamma,G}$$

$$= \frac{1}{m_{\Gamma,G}} \left( h_{\Gamma,G} \cdot id_{\Omega(\Gamma)} \cdot \sum_{x^{-1} \in V(\delta_{P_{\Gamma,G}})} \frac{\delta_{P_{\Gamma,G}}(\bar{\sigma}) \cdot \Delta_{P_{\Gamma,G}^{op}}(\bar{\sigma})}{1 - x \sigma} \right) \text{Trace}^{[e]} \Omega_{\Gamma,G}.$$ 

This gives LHS of (11.5.9), and hence Theorem is proven.

**Example.** Consider the free group $F_f$ with $f$ number of generating system $G$ (§11.1 Example 2). Using the formula (11.1.10), it is immediate to calculate

$$(11.5.8) \quad P_{F_f,G,M}(t) = \frac{1}{(1-t)(1-(2f-1)t)} \sum_{k=0}^{\infty} t^k \left( \sum_{S \in (F_f,G)_0} \varphi(S) + \sum_{S \in (F_f,G)_0} \varphi(S) \right)$$

$$= \frac{1}{1-t} \sum_{S \in (F_f,G)_0} \varphi(S)$$

$$(11.5.9) \quad P_{F_f,G,M}(t) = \sum_{S \in (F_f,G)_0} \varphi(S) + \sum_{S \in (F_f,G)_0} \varphi(S)$$

The denominator polynomial $\Delta_{F_f,G}(t) = (1-t)(1-(2f-1)t)$ has two roots 1 and 1/(2f-1). The specialization of the variable $t$ in (11.5.9) to the smaller root 1/(2f-1) gives the limit element (11.1.9). The specialization to $t = 1$ gives $\sum_{S \in (F_f,G)_0} \varphi(S)$ (see (12.13) and §12 Problem 3. iii)).
Remark. 1. The second term of the LHS of (11.5.6) belongs to the kernel of \( \pi \), since one has
\[
\pi(\Delta^{op}_{P,\text{G}}(\tilde{\sigma}))\text{Trace}^{[e]}_{\Omega_{\text{G}}} \Omega_{\Gamma,\text{G}} = m_{\Gamma,\text{G}}\Delta^{op}_{P,\text{G}}(\sigma)a^{[e]} = 0.
\]
Therefore, we ask whether
\[
\Delta^{op}_{P,\text{G}}(\tilde{\sigma})\text{Trace}^{[e]}_{\Omega_{\Gamma,\text{G}}} = 0?
\]
This is equivalent to the statement that the \( \mathbb{R}[\tilde{\sigma}] \)-module spanned by the trace elements \( \text{Trace}^{[e]}_{\Omega_{\Gamma,\text{G}}} \) is isomorphic to the \( \mathbb{R}[\sigma] \)-module \( \Omega_{\Gamma,\text{G}} \).

2. One can directly calculate the following formula:
\[
(11.5.10) \quad \pi\left(\frac{P_{\Gamma,\text{G}}M(t)}{P_{\Gamma,\text{G}}(t)}\right) = \frac{1}{1-st}.
\]
Specializing \( t \) to a root \( x \) of \( \Delta_{P}(t)=0 \) in the formula gives the Cauchy kernel \( \frac{1}{1-xs} \). Therefore, the \( \pi \) image of (11.5.6) turns out to be the formula (11.3.9).

3. If \((\Gamma, G)\) is a group of polynomial growth, then \( \Delta_{P,\text{G}}(t) = (1-t)^{l+1} \) (where \( l=\text{rank}(\Gamma)>0 \)) is never reduced. However, due to (10.6.4), one sees directly the conclusion of Theorem: \( \frac{P_{\Gamma,\text{G}}M(t)}{P_{\Gamma,\text{G}}(t)} |_{t=1} = \sum_{S \in (\Gamma, G)} \frac{\varphi(S)}{#\text{Aut}(S)} \) (c.f. (11.1.8)).

4. Due to D. Epstein [E3], we know that there is a wide class of groups satisfying Assumption ii). See the remarks and problems in the next paragraph.

§12. Concluding Remarks and Problems.

We are only at the start of the study of the space \( \Omega(\Gamma, G) \) for discrete groups and monoids. Here are some problems and conjectures for further study.

1. A formula similar to (11.5.6) should be true without assuming the finiteness of \( \Omega(\Gamma, G) \), where the formula should be rewritten as an integral formula.

**Problem 1.** Find measures \( \nu_{a} \) on \( \pi^{-1}(a) \) and \( \mu_{a} \) on the set \( \text{Sing}(P_{\Gamma,\text{G}}) \) of singularities of the series on the circle of radius \( r \) so that the following holds:

\[
(12.11) \quad \frac{\int_{\pi^{-1}(a)} \omega_{\Gamma,\text{G}} d\nu_{a}}{\int_{\pi^{-1}(a)} d\nu_{a}} = \int_{\text{Sing}(P_{\Gamma,\text{G}})} \left. \frac{P_{\Gamma,\text{G}}M(t)}{P_{\Gamma,\text{G}}(t)} \right|_{t=x} d\mu_{a,x},
\]

for \( a \in \Omega(P_{\Gamma,\text{G}}) \), where \( \omega_{\Gamma,\text{G}} \) is a tautological map from \( \Omega(\Gamma, G) \) to \( \mathcal{L}_{\mathbb{R},\text{G}} \).

2. It is known ([E3]) that, for a wide class of groups, the assumption ii) in the Theorem 6 is satisfied in a stronger (global) form: the Poincare series \( P_{\Gamma,\text{G}}(t) \) and the growth series \( P_{\Gamma,\text{G}}M(t) \) are rational functions, where the denominator polynomial \( \Delta_{\Gamma,\text{G}}(t) \) for the rational function \( P_{\Gamma,\text{G}}(t) \) is also the universal denominator for the rational functions \( P_{\Gamma,\text{G}}M(t) \). More generally, \( P_{\Gamma,\text{G}}(t) \) analytically continues to a meromorphic function on a (branched) covering domain of \( \mathbb{C} \) (in this case, \( \Delta_{\Gamma,\text{G}}(t) \) is defined only up to a unit factor).
We remark that denominator polynomial $\Delta_{\Gamma,G}(t)$ for the Poincare series $P_{\Gamma,G}(t)$ as an element of $\mathbb{C}\{t\}_{\tau_{\Gamma,G}}$ (see 11.4 Definition) is the factor of $\Delta_{\Gamma,G}(t)$ consisting of the roots $x$ with minimal $|x| = r_{\Gamma,G}$ (in case $P_{\Gamma,G}(t)$ is defined in a covering of $\mathbb{C}$, whether $|x|$ of a pole $x$ makes sense or not is unclear).

Inspired by these observations, in order to get a global understanding of the monoid $(\Gamma,G)$, we propose studying the residues of $P_{\Gamma,G}\mathcal{M}(t)$ at any root of $\Delta_{\Gamma,G}(t)$, which are defined and shown to belong to $\mathcal{L}_{\mathbb{C},\infty}$ as follows.

**Definition.** Let $x$ be a root of $\Delta_{\Gamma,G}(t) = 0$ of the multiplicity $d_x > 0$. Then, for $0 \leq i < d_x$, we define the residue of depth $i$ of the limit function $P_{\Gamma,G}\mathcal{M}(t)$ at $x$ by the formula

$$
(12.12) \quad \left. \left( \frac{d^i}{dx^i} \frac{P_{\Gamma,G}\mathcal{M}(t)}{P_{\Gamma,G}(t)} \right) \right|_{t=x}
$$

**Example.** The formula (11.1.7) is paraphrased as the formula for the residue of depth $0$ at $t = 1$.

$$
(12.13) \quad \left. \frac{P_{\Gamma,G}\mathcal{M}(t)}{P_{\Gamma,G}(t)} \right|_{t=1} = \sum_{s \in (\Gamma,G)_0} \frac{1}{\#(\text{Aut}(S))} \varphi(S).
$$

**Assertion.** The residues belong to the space $\mathcal{L}_{\mathbb{C},\infty}$ at infinity.

Proof. By the definition (8.4.1), $\overline{K}\left( \frac{P_{\Gamma,G}\mathcal{M}(t)}{P_{\Gamma,G}(t)} \right) = \sum_{n=0}^{\infty} \mathcal{M}(\Gamma_n) \frac{t^n}{P_{\Gamma,G}(t)}$, whose coefficients $\frac{t^n}{P_{\Gamma,G}(t)}$ are rational functions divisible by $\Delta_{\Gamma,G}$ and have zeros of order $d_x$ at the zero loci $x$ of $\Delta_{\Gamma,G}$. Since the kabi-map $\overline{K}$ (8.4.1) is continuous with respect to the classical topology, this implies the vanishing $\overline{K}\left( \left( \frac{d^i}{dx^i} \frac{P_{\Gamma,G}\mathcal{M}(t)}{P_{\Gamma,G}(t)} \right) \right)_{t=x} = 0$ for $0 \leq i < d_x$. $\square$

Using the all residues for all roots of $\Delta_{\Gamma,G}(t) = 0$, we introduce the global module of limit elements for $(\Gamma,G)$:

$$
(12.14) \quad \mathcal{L}(\Gamma,G) := \bigoplus_{0<r<\infty} \bigoplus_{x; \text{a root of } \Delta_{\Gamma,G}(t)=0, x \text{ s.t. } |x|=r} \bigoplus_{0 < i < d_x} \bigoplus_{|x|=r} \mathbb{C} \cdot \left( \frac{d^i}{dx^i} \frac{P_{\Gamma,G}\mathcal{M}(t)}{P_{\Gamma,G}(t)} \right)_{t=x},
$$

which is doubly filtered: one filtration is given by the absolute values $|x|$ of the roots of $\Delta_{\Gamma,G}(t) = 0$, and the other by the order $i$ of the depth of residues at $x$.

Theorem 6 in §11 states relationships between the $\overline{\tau}^{h_{\Gamma,G}}$-invariant part of the module $\overline{\Omega}(\Gamma,G)$ with the filter at $|x| = r_{\Gamma,G} := \inf\{r\}$ and the first residues part of the module $\mathcal{L}(\Gamma,G)$. We ask its generalization.

**Problem 2.** What is the relationship between the modules $\overline{\Omega}(\Gamma,G)$, $\mathcal{L}(\Gamma,G)$ and $\overline{\mathcal{L}}_{\mathbb{C},\infty}(\Gamma,G)$? Find generalization of Theorems in §11 and, in particular, of (11.4.3), (11.4.4) and (11.5.6) in this context.
3. Another important aspect of the residues is that the Poincare series \( P_{\Gamma,G,M}(t) \) and \( P_{\Gamma,G}(t) \) are series, up to variables in Conf, defined over integers \( \mathbb{Z} \). Therefore, in case \( \Delta_{\Gamma,G}(t) \) is a polynomial in \( \mathbb{Z}[t] \), they are rational functions defined over \( \mathbb{Q} \), and hence the residue (12.2) is defined over the algebraic number field \( \mathbb{Q}(x) \) for a root \( x \) of \( \Delta_{\Gamma,G}(t) = 0 \). The action of an element \( \sigma \) of the Galois group of the splitting field of \( \Delta_{\Gamma,G}(t) \) commutes with the Kabi-map \( \mathcal{K} \) (8.4.1), and seems to bring the space spanned by the residues at \( x \) to that at \( \sigma(x) \), and hence induces an action on \( L(\Gamma,G)_\mathbb{Q} \).

Actually, in several interesting examples (surface groups by Cannon [Ca], Artin monoids [Sa5,6]), we observe that the denominator polynomial \( \Delta_{\Gamma,G}(t) \) is, up to the factor of a power of \( 1-t \), irreducible. In view of the above observation, the limit space \( C \cdot \Omega(\Gamma,G) \) studied in the present paper is not “isolated” but related by the action of the Galois group with the residue modules at other places \( x \) with \( |x| > r_{\Gamma,G} \). However, no concrete example is yet known.

On the other hand, the residue module at \( t = 1 \) is “isolated” (with respect to the Galois group action). There are a few examples of higher poles at \( t = 1 \) (see [Sa6]), but we do not yet understand their nature and role.

**Example.** ([Sa2]) Consider the infinite cyclic group \((\mathbb{Z}, \pm 1)\). Then, the growth function is given by \( P_{\mathbb{Z},\pm 1}(t) = 1 + t(1-t)^{-2} \) and the principal part of the singularities of \( P_{\mathbb{Z},\pm 1,M}(t) \) is given by \( P_{\mathbb{Z},\pm 1,M}(t) = \sum_{m=0}^{\infty} \varphi(I_m) \left( \frac{2}{(1-t)^2} - \frac{m-1}{1-t} + R_m \right) \) where \( I_m \) is a linear graph of \( m \)-vertices and \( R_m \) is a polynomial of degree \(<[(m-1)/2]\) in \( t \). Therefore, the two residues of depth 0 and 1 at \( t = 1 \) are given by

\[
\begin{align*}
\left. \frac{P_{\mathbb{Z},\pm 1,M}}{P_{\mathbb{Z},\pm 1}} \right|_{t=1} & = \sum_{m=0}^{\infty} \varphi(I_m), \\
\left. \left( \frac{d}{dt} \frac{P_{\mathbb{Z},\pm 1,M}}{P_{\mathbb{Z},\pm 1}} \right) \right|_{t=1} & = \sum_{m=0}^{\infty} \frac{m-1}{2} \varphi(I_m),
\end{align*}
\]

span the space \( L_{\mathbb{R},\infty}(\mathbb{Z}, \pm 1) \), where the first one is the limit element in \( \Omega(\mathbb{Z}, \pm 1) \).

In view of these observations, we ask the following problems.

**Problem 3.** i) Describe the action of the Galois group of the splitting field of \( \Delta_{\Gamma,G}(t) = 0 \) on \( L(\Gamma,G)_\mathbb{Q} \). Clarify the role of the classical part \( C \cdot \Omega(\Gamma,G) \).

ii) When is the denominator polynomial \( \Delta_{\Gamma,G}(t) \), up to a factor of a power of \( 1-t \), irreducible over the integers \( \mathbb{Z} \)?

iii) What is the meaning of the residue module at \( t = 1 \):

\[
L(\Gamma,G)_1 := \bigoplus_{0 \leq i < d_1} \mathbb{R} \cdot \left. \left( \frac{d^i}{dt^i} \frac{P_{\Gamma,G,M}(t)}{P_{\Gamma,G}(t)} \right) \right|_{t=1}
\]

4. Including Machi’s example, there are a number of examples where \( \Omega(P_{\Gamma,G}) \) is finite. However, we do not know an example when \( \Omega(\Gamma,G) \) is finite except for the simple accumulating cases (e.g. (11.1.9)). We conjecture the following.
Conjecture 4. For any hyperbolic group $\Gamma$ with any finite generating system $G$, the limit space $\Omega(\Gamma, G)$ is finite accumulating.

Evidence is provided by Coornaert [Co]: if $\Gamma$ is hyperbolic, then there exists positive real constants $c_1, c_2$ such that $c_1 r_{\Gamma, G}^{-n} \leq \#\Gamma_n \leq c_2 r_{\Gamma, G}^{-n}$. This implies that the property in Fact in the proof of Assertion in (11.3) holds for hyperbolic groups without assuming the finite rational accumulation of $\Omega(P_{\Gamma, G})$. We further expect that Coornaert’s arguments can be lifted to the level of $A(S, \Gamma_n)$.

5. The following groups are not hyperbolic. However, because of their geometric significance, it is interesting to ask the following problems.

Problem 5.1 Are the limit spaces $\Omega(\Gamma, G)$ for the following pair of a group and a system of generators simple or finite?

1. Artin groups of finite type with the generating systems given in [BS] [Sa4],
2. The fundamental groups of the complement of free divisors with respect to the generating system defining positive homogeneous monoid structure [S-I].

In these examples, $G$ generates a positive homogeneous monoid $\Gamma_+$ in $\Gamma$ such that $\Gamma = \bigcup_{n=0}^{\infty} \Delta^{-n} \Gamma_+$, where $\Delta$ is a fundamental element.

Problem 5.2 Clarify the relationship among $\Omega(\Gamma, G)$, $\Omega(P_{\Gamma, G})$, $\Omega(\Gamma_+, G)$ and $\Omega(P_{\Gamma_+, G})$ (see [Ba] Chap.13) for $\Gamma_+ = (\mathbb{Z}_+)^2$, and [Sa5] for Artin monoids.
