ABSTRACT

China aster (Callistephus chinensis L. (Nees.)) is a semi hardy annual and commercial flower crop belonging to the family Asteraceae. China aster is a self pollinated crop, but the natural outcrossing is approximately 10 per cent as reported and described floral biology of China aster. The study results revealed that high heritability along with high genetic advance existed in cross viz., AAC-1 × Arka Poornima and Arka Kamini × P G Purple for number of flowers per plant, individual flower weight and flower yield per plant. Thus, these characters could be improved through simple selection procedure due to the presence of additive type of gene action.

Introduction

The present day China aster had been developed from single wild species. According to Emsweller et al., (1937), the original plant had single flower with two to four rows of blue, violet or white ray florets. The first change in the flower type was the prolongation or development of central florets and the production of quilled flowers. Creation and utilization of variability using proper breeding procedure is a pre-requisite for the genetic improvement of any crop. Generally, amount of variability generated is more in the early segregating generations as compared to later generations. The knowledge of high estimate of heritability and genetic advance as per cent mean assist the breeders to decide and select superior plants, so that the plants can perform superior for the traits of interest in subsequent generation. Being a self pollinated crop, there is need of high yielding variety of China aster with specific colored flowers to overcome farmer’s predicament. Hence keeping all these in view, the present study was undertaken to assess and estimate the magnitude of variation among the F4 population with respect to various traits which can be further utilized in crop improvement programme.
Materials and Methods

The study was conducted during the year 2018-2019 at Department of Floriculture and Landscape Architecture, Kittur Rani Channamma Collage of Horticulture, Arabhavi. The F4 population of two crosses viz., AAC-1 × Arka Poornima and Arka Kamini × P G Purple were selected based on the superior yield and yield contributing characters. The parent AAC-1 is locally cultivated genotype with yield of 50 flowers per plant and flower diameter of 6 cm; Arka Poornima has flower yield per plant of 25 flowers and flower diameter of 5 cm; Arka Kamini yields about 50 flowers with flower diameter of 6 cm, and P G Purple released by MPKV, Rahuri has yield of 42 flowers per plant. One month old seedling were transplanted into the main field with spacing of 30×30cm. Observations were recorded for the best 5 plants in each line for plant height (cm), number of branches per plant, flower stalk length (cm), flower diameter (cm), days taken for flower bud initiation, days to 50 percent flowering, duration of flowering (days), number of flowers per plant, individual flower weight (g) and flower yield (g/plant). The genotypic and phenotypic coefficient of variation was estimated according to the methods of Burton and De-Vane (1953). Heritability in broad sense was calculated as per method given by Johnson et al., (1955) and Robinson et al., (1949). The expected genetic advance as per cent of mean was worked out as suggested by Johnson et al., (1955).

Results and Discussion

Among the two crosses, AAC-1 × Arka Poornima cross was found to be significantly superior for plant height, number of branches, leaf area, flower diameter, stem girth, plant spread in north -south and east-west direction, shelf life (days), days taken for flower bud initiation, number of flowers per plant, individual flower weight and flower yield per plant (Table 1). The cross Arka Kamini × P G Purple recorded highest in flower stalk length. Both crosses differed significantly for all traits except for days to flower bud initiation, duration of flowering, flower diameter and individual flower weight.

The estimates of phenotypic coefficient of variation (PCV) values were relatively higher than those of genotypic coefficient of variation (GCV) for all the traits (Table 1) which indicated greater genotype x environment interactions. The result is in accordance with the report of Singh and Mishra (2006) High phenotypic coefficient of variation (PCV) and genotypic coefficient of variation (GCV) was found for number of flowers per plant, individual flower weight, flower yield(g) per plant and for growth characters like number of branches per plant and leaf area.(Karuppaiah and Kumar, 2011 in marigold; Vikas et al., 2011 in dahlia and Rajiv et al., 2014 in China aster). There was less difference between PCV and GCV indicating less influence of environment on this trait (Suma and Patil, 2016 in daisy). Moderate PCV and GCV were obtained for flower stalk length, plant height and stem girth in both the crosses, AAC-1 × Arka Poornima and Arka Kamini × P G Purple.

It indicated that selection would be difficult for these characters, as the genotypic effect would be modified by the environmental effect. These results are in agreement with the results of Jankiram and Rao (1991) in marigold, Mishra et al., (2013) in chrysanthemum and Rachappa (2014) in China aster.

The crosses AAC-1 × Arka Poornima and Arka Kamini × P G Purple showed almost high heritability for all the traits shelf life in AAC- 1 × Arka Poornima.
**Table 1** Estimates of mean, range, components of variance, heritability and genetic advance for growth, quality and yield parameters in F₄ populations of two crosses in China aster

These findings suggest the scope for improvement of the character through direct selection. The results of the present study were supported by those of Vikas et al., (2011) and Rachappa (2014) for flower stalk length, flower diameter, ray floret length and disc diameter in China aster. Karuppaiah and Kumar (2011) in marigold recorded high heritability for number of flowers per plant, individual flower weight and flower yield per plant. Anuja and Jahnavi (2012) reported similar results in marigold for plant height, number of branches and number of leaves. Heritability along with genetic advance increases the efficiency of selection in a breeding programme by assessing the influence of environmental factors and additive gene action. In both the crosses high heritability along with high genetic advance as per cent mean for number of flowers per plant, individual flower weight and flower yield per plant and vase life. These results are in line with the findings of Karuppaiah and Kumar (2011) in marigold and Rajiv et al., (2014) in China aster for stalk length, flower diameter, disc diameter, number of flowers per plant, individual flower weight and flower yield per plant. The cross Arka Kamini × P G Purple recorded high heritability along with high genetic advance for plant height and stem girth. similar results are in accordance with the finding of Rachappa (2014).This revealed that the characters are governed by the additive type of action and these characters are useful for phenotypic selection.

The study results revealed that high heritability along with high genetic advance existed in cross vīz., AAC-1 × Arka Poornima and Arka Kamini × P G Purple for number of flowers per plant, individual flower weight and flower yield per plant. Thus, these characters could be improved through simple selection procedure due to the presence of additive type of gene action.
