ABSTRACT

This research aimed to prove the difference of TLR4 and p65NF-kB subunit expression between children with steroid-sensitive nephrotic syndrome (SSNS) and those with steroid-resistant nephrotic syndrome (SRNS) and to find out the correlation between expression of TLR4 and p65NF-kB on children with SRNS. Twenty three patients of idiopathic nephrotic syndrome patients (INS) were enrolled in this study and classified into two groups—those with SSNS (11 patients) and SRNS (12 patients). Peripheral Blood Mononuclear Cells (PBMC) isolation was performed, taken from 5 ml patients’ blood samples, followed by monocyte isolation of PMBC using monocyte culture. Examination of TLR4 and p65NF-kB expression from monocyte's cells culture was performed using flow cytometry. The result showed that the differences of TLR4 expression between SSNS and SRNS was significant (p=0.012), The differences of p65 NF-kB expression between SSNS and SRNS showed an insignificant correlation (p=0.880). Pearson correlation test between the expression of TLR4 and p65NF-kB showed no significant correlation (p=0.472), while Spearman correlation test to see the relationship between expression of TLR4 and SRNS produced correlation value of 0.512 and its importance p value was 0.013 (p<0.05). There is a significant difference of TLR4 expression between SRNS and SSNS and there is also a significant correlation between expression of TLR4 and SRNS, that proved TLR4 has an important role in steroid resistance of nephrotic syndrome.

Keywords: INS, SSNS, SRNS, TLR4 expression, p65 NF-kB expression

INTRODUCTION

Nephrotic syndrome (NS) is a group of clinical symptom consisting of massive proteinuria, hypoalbuminemia, oedema and is also accompanied by hypercholesterolemia. In some cases, some microscopic hematuria symptoms, hypertension, and temporarily increasing urea level as well as creatinine are also seen. Nephrotic Syndrome is the most frequently renal disease on children [1,2,3]. Idiopathic nepho-
Based on the reports on treatment using steroid, nephrotic syndrome is divided into two, namely steroid-sensitive nephrotic syndrome (SSNS) and steroid-resistant nephrotic syndrome (SRNS). In the former group, there is improved clinical conditions (remission) within 4 weeks of initial therapy while the latter shows no improved clinical states [5,6]. In the initial corticosteroid treatment, most MCD (94%) undergoes total remission (responsive), while in FSGS it accounts for 80-85%, irresponsible. Generally, SSNS incidence level is nearly 80-90%, while SRNS comprises 10-20 % [5,7].

The most important factor in determining prognosis on children with nephrotic syndrome is their response to steroid (Glucocorticoid) treatment. Glucocorticoid is one of the anti-inflammatory molecules that works by binding to glucocorticoid receptor-α (GR-α) through transcription factor mediator mechanism. Glucocorticoid does not bind to glucocorticoid receptor-β (GR-β) or transactivation target gene (8). The role of glucocorticoid anti-inflammatory effect is affected by its capability to inhibit the activities of two transcription factors which are activator protein-1 (AP-1) and nuclear factor-kappa B (NF-κB) [9]. Nuclear factor-kappa B is a heterodimer of p50 and p65 subunit as an inactive form in which in cytoplasm it binds to inhibitor kappa-B (I-κB). After translocating into nucleus, heterodimer NF-κB will be bound to specific DNA and activates transcription of cytokine gene that has a role in immune response and inflammation [10,11]. Currently, there have still been many controversial research findings related to expression of Nfkb in PBMC of INS. Aviles et al., (2004) showed the decreased expression of p65Nfkb subunit in lymphocyte cell of the SRNS while the different finding was illustrated by Audred et al., (2012) in which there was an increased expression of NF-kB of CD4+ lymphocyte cell on INS [12,13].

Until recently, etiopathogenesis of nephrotic syndrome in children is still unclear. There are, however two main factors, an immunological dysfunction and genetic factor. Research regarding the role of Toll like receptor (TLR) in various diseases due to immunological defect is now developing. Toll like receptor is an important component of innate immunity, having an important role in the early detection of pathogen associated molecular patterns (PAMPs) and then activates an adaptive immune response. Toll like receptor is expressed from various types of cells of body immunity, especially those involved in the first line of body defence toward pathogen [14]. In nephrotic syndrome pathogenesis, there is new evidence showing the activation function of nephrotic syndrome on innate immune via TLR initiated by microbial products that can directly affect podocyte of the kidney. In addition, microbial products also indirectly affect podocyte through antigen presenting cell (APC). The activated APC cells will secrete nuclear factor kappa B (NF-kB); a transcription factor directly affecting TH2 adaptive immune response and directly increases expression of CD80 in podocyte. However, research related to the involvement of TLR on nephrotic syndrome has not been yet much conducted [15]. This research will try to find out the role of TLR4 and p65NfKB subunit in relation to the occurence of idiopatic nephrotic syndrom.

**MATERIALS AND METHODS**

**Ethics**

This study has got research ethical clearance, issued by Health Research Ethics Commision from dr. Saiful Anwar General Hospital, Malang, East Java, Indonesia.

**Research subjects**

The research subjects were children that diagnosed as idiopathic steroid-resistant nephrotic syndrome and idiopathic steroid-sensitive nephrotic syndrome. The criteria of the former group, idiopathic steroid-resistant nephrotic syndrome in which remission does not occur using full dose prednison administration (full dose) 2mg/kgBW/day for 4 weeks. While the criteria of idiopathic steroid-sensitive nephrotic syndrome is nephrotic syndrome that having remission using full dose prednison administration 2mg/kgBW/day for 4 weeks. Remission is negative proteinuria or trace (proteinuria < 4 mg/m2LPB/jam) is performed in three respective days in a week. Inclusive criteria of research subjects are patients with idiopathic nephrotic syndrome, aged between 1 and 14 and the patient’s family permits the child to participate in this study after informed consent is notified. Exclusive criteria of study subjects include secondary nephrotic syndrome which is a
nephrotic syndrome caused by external renal factor such as those exposed to chemicals substances/drug, those derived from systemic diseases such as lupus eritematosus, purpura Henoch Schonlein, some infectious diseases such as malaria, hepatitis and patients with congenital infantile nephrotic syndrome which is nephrotic syndrome that starts to show its symptoms in the patient’s early life years.

Flow cytometry examination.

The study started with blood withdrawal amounting 5 ml, given EDTA, which was then followed by isolation of PBMC by Ficoll Hypaque (Biomedicals USA, cat#50494, 1.077g/ml). Analysis of flow cytometry was performed using Fluorescence Activated Cell Sorter (FACS Calibur). The first analysis step was performing gating strategies on CD14 monocyte cell (anti-human CD14-PerCP/Cy5.5 antibody cat#325622, Biolegend, USA, which was then followed by analysis of TLR4 expression on cell membranes, labeled with anti human TLR 4-PE monoclonal antibody cat 312806, Biolegend, USA. The intracellular/cytoplasmic p65 NF-kB was determined by staining labeled with anti NF-kBp65-FITC polyclonal human antibody (cat b5-0465R, Bioss). Percentage of TLR4 and p65 NF-kB expression was analyzed using cell questpro software.

Statistical analysis

Shapiro-Wilk test was used to test the distribution of normal data, while test of homogeneous data was performed using Levene test. Comparison variables of two groups (SSNS and SRNS) were analyzed using unpaired t-test for TLR4 and Mann-Whitney test for p65 NF-kB. Correlation between groups was tested using Pearson correlation test. It is significant if p value <0.05. All data was analyzed using Statistical Package for the Social Sciences (SPSS 15) for Windows.

RESULTS AND DISCUSSION

Subjects Characteristic

This research used cross-sectional design with consecutive sampling. There were 23 patients of idiopathic nephrotic syndrome divided into two groups which were SSNS, accounting for 11 patients, and SRNS patients, which were 12 patients. The basic characteristics of each group are presented in table 1.

| Characteristic       | SSNS (n=11) | SRNS (n=12) | Total (n=23) | P   |
|----------------------|-------------|-------------|--------------|-----|
| Gender               |             |             |              |     |
| Male                 | 5 (45%)     | 11 (91.7%)  | 16 (69.6%)   | 0.892 |
| Female               | 6 (55%)     | 1 (8.3%)    | 7 (30.4%)    |     |
| Age                  |             |             |              | 0.248 |
| ≤ 2 year             | 1 (9.1%)    | 0 (0%)      | 1 (4.4%)     |     |
| 2-6 year             | 3 (27.3%)   | 6 (50%)     | 9 (39.1%)    |     |
| ≥ 6 year             | 7 (63.6%)   | 6 (50%)     | 13 (56.5%)   |     |
| Nutritional status   |             |             |              | 0.045 |
| Good status          | 9 (81.8%)   | 5 (41.7%)   | 14 (60.9%)   |     |
| Undernourished       | 2 (18.2%)   | 6 (50%)     | 8 (34.8%)    |     |
| Malnourished         | 0           | 1 (8.3%)    | 1 (4.3%)     |     |
The average age of the study subject is 7.59 ± 3.52 years and 6 years old or more were the most prevalence aged (56.5%). From 12 patients diagnosed with SRNS, 8.3% had a malnourished status, 50% had undernourished status and 41.7% had good nutritional status, and from 11 patients diagnosed with SSNS, 18.2% had undernourished status and 81.8% had good nutritional status.

The difference on TLR4 expression between SSNS and SRNS

Based on the normality test using Saphiro-Wilk, it was noted that variable data to be tested, expression of TLR4, indicated a significance result of 0.620 (p>0.05). It can then be concluded that variable data spreads TLR4, following standard distribution, allowing the study with t-test.

**Figure 1.** The difference expressions on TLR4 between SRNS and SSNS. A. Representative histograms are showing expression of TLR4 in SRNS group (M2=94.14%) higher than SSNS group (M1=54.83%). B. Mean data of TLR4 expression (%) from 11 samples in SSNS group and 12 samples in SRNS group, data shows a significant difference in the expression of TLR4 in SRNS group compared to SSNS group, *p value 0.012 (p<0.05).

**Figure 2.** The differences expression of p65NF-kB subunit between SRNS and SSNS. A. Representative histograms of p65NF-kB expression showed almost similar data between SRNS group (M2 = 58.90%) compared to SSNS group (M1 = 55.89%). B. Mean data of p65NF-kB expression (%) from 11 samples in SSNS group and 12 samples in SRNS group, the data shows no significant difference in the expression of p65 NF-kB of SRNS group compared to SSNS, p value 0.551 (p >0.05).
Before performing unpaired t-test, the result of homogeneous analysis of various data needed to be found out. The analysis result of different data for TLR4 expression with Levene test showed a significance level of 0.318 (p>0.05). Then it can be summed up that data on patients’ TLR4 expression is homogeneous, allowing the analysis of independent t-test with the assumption of homogeneous data variation (equal variance assumed). The difference expression of TLR4 between SSNS and SRNS patients showed t value of 2.742 with its importance p value of 0.012, smaller than alpha 0.05. It can then be concluded that there was a significant difference of TLR4 expression between patients with SRNS and SSNS. The difference is depicted in which the average expression of TLR4 expression of SRNS patients are likely to be higher (mean = 64.5%) than that of SSNS patients (mean = 60.3%).

The correlation between expression of TLR4 and SRNS.

Based on the correlation test using Spearman correlation, it was noted that the correlation between expression of TLR4 and SRNS had a correlation coefficient value of 0.512 with its significant value of 0.013 (p<0.05), so that it can be summarized that there was a significant correlation between expression of TLR4 and SRNS. The higher TLR4 expression, the higher occurrence of SRNS (due to its positive correlation coefficient), while the lower expression of TLR4, followed by the lower occurrence of SRNS.

The correlation between expression of p65NF-kB and SRNS.

Based on correlation test using Spearman test, it was noted that the correlation between expression of p65NF-kB and SRNS has correlation coefficient value of 0.039, where the significant value is 0.858 (p>0.05), so that it can be concluded that there was an insignificant correlation between expression of p65NF-kB and SRNS.

One of the clinical features of INS is the recurrence after viral and bacterial infection especially on children. The phenomenon may be related to dysfunctional innate body immunity. This innate immunity response occurs several hours after infection and depends on the introduction of microbial products by specific receptors which are TLRs, which is expressed by APC, macrophage, neutrophil, natural killer (NK) cells, epithelial and endothelial cells. Toll Like Receptor (TLR) involvement triggers cascade signal involving MyD88, IRAK and TRAF6, resulting in activation of NF-kB and AP-1 pathways, which then induces inflammatory gene activation such as TNFα, IL1, IL6 and IL8 [19]. Nuclear Factor Kappa Beta (NF-kB) signal activation on non-cell T population during INS relapse indicates the involvement of innate immunity cells in this process [20]. This hypothesis is mostly supported by data showing upregulation of many genes recruited in innate immunity response such as regulated on activation, normal T cell expressed and secreted (RANTES), TNF receptor associated factor 6 (TRAF6), IL1, and IFNαR [21].
This study notes an insignificant difference in expression of p65NF-kB subunit between SSNS and SRNS groups despite a higher average value of p65NF-kB subunit on SRNS patients (mean = 61.3%) than SSNS patients (mean = 60.7%). Some research shows different results of NF-kB expression on PBMC nephrotic syndrome patients. Research conducted by Aviles et al. (2004) showed that there was a decrease of p65NF-kB subunit expression on SRNS patient’s lymphocytes. Corebima et al. (2010) indicated an insignificant difference of p65NF-kB subunit expression between SSNS and SRNS groups, but there was an increased of p65NF-kB subunit activity on SRNS. On the other hand, research conducted by Krisni, (2012) found that p65NF-kB expression on SRNS is highest compared to SSNS and control. Moreover the same result is also indicated by Audrad et al. (2012) which found the increased expression of CD4+ lymphocytes NF-kB on INS who undergo a relapse [12,13,23,24]. A quick relapse on INS, as a result, of immunogen exposure supported the involvement of innate immunity systems in which signal path of NF-kB plays a central role [25]. Idiopathic nephrotic syndrome relapsed showed an increased expression of p65/p50 heterodimer NF-kB and decreased expression of NF-kB when SSNS patients are administered dexamethasone. The hindrance of NF-kB and AP-1 was an important molecular mechanism of glucocorticoid effect on SSNS therapy [26].

This study also indicates an insignificant correlation between TLR4 and p65NF-kB subunit on SRNS. The result can also result from the sample study who are still undergoing treatment of immunosuppressant or Cytostatic. The other cause may be due to a fewer samples; thus it is necessary to conduct further research.

**CONCLUSIONS**

This study shows an increased expression of TLR4 on SRNS compared to SSNS; however, there is no different expression of p65NF-kB. There is also a significant correlation between expression of TLR4 and SRNS with its significant value of 0.013 (p<0.05), so there should be further study to examine the role of TLR4 and p65NF-kB on pathogenesis of steroid resistance on nephrotic syndrome by including more samples and using a different method.
