Abstract. In this work, multi-variable derivative-free optimization algorithms for unconstrained optimization problems are developed. A novel procedure for approximating the gradient of multi-variable objective functions based on non-commutative maps is introduced. The procedure is based on the construction of an exploration sequence to specify where the objective function is evaluated and the definition of so-called gradient generating functions which are composed with the objective function such that the procedure mimics a gradient descent algorithm. Various theoretical properties of the proposed class of algorithms are investigated and numerical examples are presented.

1. INTRODUCTION

In this paper, we propose a novel class of derivative-free optimization algorithms based on a concept introduced in [11]. The key idea is to use non-commutative maps to evaluate the objective function at certain points such that the composition of the maps approximates a gradient descent step. The class of proposed algorithms is built upon two main ingredients: an exploration sequence indicating where the objective is to be evaluated, and the (gradient) generating functions, which are composed with the objective function in such a way that an approximation of a gradient descent step is obtained. The resulting algorithms have several noteworthy properties. For example, the algorithms are sometimes able to overcome local minima and robust against noisy objective function evaluations. Such properties are also known from so-called extremum seeking algorithms (cf. e.g. [12, 13, 14, 15]), which are related to our proposed algorithms [7, 11].

In our preliminary work [11], the algorithms were limited to optimization problems with one decision (optimization) variable or to a coordinate-wise application of the gradient approximation scheme. Moreover, only a special case of generating functions were discussed and no full characterization was given. In another related work [16], the optimization procedure of [11] was extended to discrete-time extremum seeking problems, but still limited to one optimization variable.

More broadly related work in terms of gradient approximation schemes are for example finite difference approximations [17, 18], simultaneous perturbation stochastic approximations [5], and random directions stochastic approximations [19]; in [20] those approximation techniques are applied to the aforementioned extremum seeking problems. These methods are based on so-called sample averaging of function evaluations, i.e., the neighborhood of the current candidate solution is explored to ap-
proximate the local gradient of the optimization objective. In contrast, in the presented work, no numerical differentiation is performed to extract gradient information, instead a kind of numerical integration scheme is utilized to approximate first order information.

The main contribution of this work is fourfold: 1) a constructive procedure for determining suitable exploration sequences for multi-variable optimization problems is presented, 2) a general class of (gradient) generating functions is characterized, 3) the so-called single and two-point algorithms in [11] and [16] are extended to the multi-variable case, and 4) a toolbox is developed to easily design and apply the novel class of optimization algorithms to unconstrained optimization problems.

Notation. The set of real numbers equal or greater than \( k \) is denoted by \( \mathbb{R}_{\geq k} = \{ x \in \mathbb{R} | x \geq k \} \). The class of \( k \)-times continuously differentiable functions is denoted by \( C^k(\mathbb{R}^n, \mathbb{R}) \). \( I \in \mathbb{R}^{n \times n} \) stands for the \( n \)-dimensional unit matrix, \( \mathbf{1} \in \mathbb{R}^n \) for the \( n \)-dimensional all-one vector, and \( e_i \in \mathbb{R}^n \) for the \( i \)-th \( n \)-dimensional unit vector. The matrix \( P \in \mathbb{R}^{n \times n} \) has the principal submatrix \( P_{1,1} \in \mathbb{R}^{r \times r} \) with \( r < n \). The bijective mapping \( \pi : \{1, \ldots, n\} \rightarrow \{1, \ldots, n\} \) with \( n \in \mathbb{N} \) denotes a permutation function. A sequence \( w_0, \ldots, w_{m-1} \) of length \( m \) is denoted by \( \{w_\ell\}_{\ell=0}^{m-1} \). The ceiling and floor operator are defined as \( \lceil x \rceil : = \max\{k \in \mathbb{Z} | k \leq x \} \) and \( \lfloor x \rfloor : = \min\{k \in \mathbb{Z} | k \geq x \} \), respectively. A function \( f(x; e) : \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}^n \) is said to be of order \( O(e) \), if for all compact sets \( \mathcal{V} \subseteq \mathbb{R}^n \) there exist an \( M \in \mathbb{R}_{>0} \) and \( \bar{e} \in \mathbb{R}_{>0} \) such that for all \( x \in \mathcal{V} \) and \( e \in [0, \bar{e}] \), \( |f(x; e)| \leq Me \). The operator \( \text{mod} \) takes to integers \( k \) and \( n \) and returns an integer \( k \) mod \( n \), equal to the remainder of the division of \( k \) by \( n \). A compact set with center point \( x^* \in \mathbb{R}^n \) radius \( \delta \in \mathbb{R}_{>0} \) and denoted by \( B_{x^*} \subseteq \mathbb{R}^n \) is defined as \( \{ x \in \mathbb{R}^n : \| x - x^* \|_2 \leq \delta \} \).

2. PROBLEM STATEMENT AND PRELIMINARIES

2.1. Problem Statement

In this work, we develop a class of algorithms to solve unconstrained minimization problems

\[
\min_{x \in \mathbb{R}^n} J(x) \tag{1}
\]

for which a closed form expression of \( J : \mathbb{R}^n \rightarrow \mathbb{R} \) may be lacking, and only zero-order information in terms of function evaluations are available to find a local minimizer \( x^* \in \mathbb{R}^n \) of \( J \). The algorithms we propose are of the form

\[
x_{k+1} = M_k^{\sqrt{h}}(x_k, J(x_k)), \quad k \geq 0, \tag{2}
\]

where we call \( M_k^{\sqrt{h}} : \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}^n \) the transition map and \( h \in \mathbb{R}_{>0} \) is the step size. The main idea is to design the transition maps in such a way that for every \( k \in \mathbb{N} \), the \( m \)-fold composition of these maps, i.e.,

\[
x_{k+m} = \left( M_{k+m-1}^{\sqrt{h}} \circ \cdots \circ M_k^{\sqrt{h}} \right) (x_k, J(x_k)) \tag{3}
\]

approximates a gradient descent step, i.e.,

\[
x_{k+m} = x_k - h \nabla J(x_k) + O(h^{3/2}) \tag{4}
\]

as visualized in Figure 1.

Figure 1. An illustration of the presented optimization algorithms based on non-commutative maps. Effects of non-commutativity are utilized to approximate the negative gradient of the optimization objective in \( m \) steps (i.e., \( m = 4 \) in this illustration).

Hereby, we impose the following structure for the transition maps

\[
M_k^{\sqrt{h}}(x_k, J(x_k)) = x_k + \sqrt{h} a_1 s_k \left( f(x_k) \right) + \sqrt{h} a_2 s_k \left( g(x_k) + \sqrt{h} s_k \left( J(x_k) \right) \right) \tag{5}
\]

with parameters \( a_1, a_2 \in \mathbb{R} \) where \( a_1 + a_2 \neq 0 \). We call \( s_\ell : \mathbb{R} \rightarrow \mathbb{R}^n \) the evaluation map, \( f, g : \mathbb{R} \rightarrow \mathbb{R} \) the generating functions and \( u_\ell, v_\ell \in \mathbb{R}^n \) the \( m \)-periodic exploration sequences. Note that for \( a_2 \neq 0 \), only two evaluations of \( f \) per iterations are necessary. We elaborate on the choice of this structure for the algorithm in the next section. The main goal of this work is to characterize and design

1. \( m \)-periodic exploration sequences \( u_\ell, v_\ell \), and

2. gradient generating functions \( f \) and \( g \),

such that (2) with transition map (5) yields (4).

We will at various points make the use of one or both of the following assumptions.
(A1) The functions \( f, g \) are of class \( C^2(\mathbb{R}, \mathbb{R}) \) and the objective function \( f \) is of class \( C^2(\mathbb{R}^n, \mathbb{R}) \).

(A2) The objective function \( f \) is radially unbounded and there exists an \( x^* \in \mathbb{R}^n \) such that \( \nabla f(x)^\top(x - x^*) > 0 \) for all \( x \in \mathbb{R}^n \setminus \{x^*\} \).

We note that (A2) will not be required for the design of the algorithms, but only when we analyze their performance. The implementation of the algorithms, however, is not limited to the class of objective functions satisfying (A1).

### 2.2. Related Results

The structure of the transition map in (5) was introduced by the authors of the present work in [11] for one dimensional problems. Therein, two cases were considered, specified by the parameter setting \([a_1 a_2] = [1 0] \), as so-called single-point map

\[
M_k^\Pi(x_k, J(x_k)) = E_k^\Pi(x_k, J(x_k)) := x_k + \sqrt{h} s_k(J(x_k))
\]

(6)

and by \([a_1 a_2] = [1/2 1/2] \), as so-called two-point map

\[
M_k^\Pi(x_k, J(x_k)) = H_k^\Pi(x_k, J(x_k)) := x_k + \sqrt{h} \left[s_k \left(J(x_k)\right) + \frac{\partial f}{\partial x} \frac{\partial g}{\partial x} \right]
\]

(7)

The algorithms relying on transition maps (6) and (7) are called single and two-point algorithm, respectively, reflecting that the number of function evaluations of \( J \) at each iteration is one and two. This type of map structure was inspired by the well-known Euler and Heun (trapezoidal) numerical integration methods respectively (thus the naming of the maps \( E \) and \( H \)), i.e., executing a single integration step with step size \( \sqrt{h} \) of the differential equation

\[
\dot{x}(t) = s(J(x(t))) = f(J(x(t))) u(t) + g(J(x(t)) v(t)
\]

(8)

with piece-wise constant \( m \sqrt{h} \)-periodic inputs \( u(t), v(t) \in \mathbb{R}^n \) for \( t \in [\ell \sqrt{h}, (\ell + 1) \sqrt{h}] \) with \( \ell \in \mathbb{N} \), yields (6) and (7), respectively. Note that (8) is well known as an approximate gradient descent flow in the context of extremum seeking control (cf. [12]). For a detailed explanation of the proposed class of algorithms and the continuous-time algorithm (8) plus how non-commutativity comes into play, we refer to [11, 16].

For the coordinate-wise descent case (see Lemma 1 and Lemma 2 in [11]) the choice of exploration sequences

\[
u_\ell = \bar{u}_\ell e_i, \quad v_\ell = \bar{v}_\ell e_i \quad \text{with} \quad i = [\ell/4] \mod(n) + 1
\]

\[
\begin{align*}
1 & \ell = 0 \\
0 & \ell = 1 \\
-1 & \ell = 2, \quad \bar{v}_\ell = \begin{cases} 0 & \ell = 2 \\
-1 & \ell = 3 \\
\end{cases} \\
0 & \ell = 3
\end{align*}
\]

(9)

with \( m = 4n \) leads to the evolution of \( x_k \) with \([a_1 a_2] = [1 0] \) such that

\[
x_{k+m} = x_k + h \left\{ [f, g](J(x_k)) - \frac{1}{2} \frac{\partial(f^2 + g^2)}{\partial J}(J(x_k)) \right\} \nabla J(x_k) + O(h^{3/2})
\]

(10)

and with \([a_1 a_2] = [1/2 1/2] \) such that

\[
x_{k+m} = x_k + h \left\{ [f, g](J(x_k)) \right\} \nabla J(x_k) + O(h^{3/2}),
\]

(11)

where \([f, g] := \frac{\partial f}{\partial x} \frac{\partial g}{\partial x} - \frac{\partial f}{\partial x} \frac{\partial g}{\partial x} \) is the Lie bracket of \( f \) and \( g \). A simple calculation shows that the term in brackets in (10) and (11) is identical to \(-1 \) for \( f(J(x)) = \sin(J(x)) \) and \( g(J(x)) = \cos(J(x)) \), hence (4) is recovered. The exploration sequence above is constructed in such a way that components of the gradient are approximated sequentially for the multi-dimensional setting, hence, coordinate-wise. In Figure 2, the exploration sequence and the gradient approximation is visualized for the scalar case \( x_k \in \mathbb{R} \) \((n = 1, m = 4) \). In summary, the existing procedure is limited and mimics a coordinate-wise descent algorithm. Further, only a single exploration sequence was presented as well as a single pair of generating functions. There are, however, many ways to construct exploration sequences and generating functions, especially in the multi-variable case. Since different exploration sequences and generating functions lead to different properties of the algorithm, it is the goal of this work to provide solutions for a flexible design and constructions of exploration sequences in the multi-variable setting and to characterize a large class of generating functions.

### 3. MAIN RESULTS

#### 3.1. Problem Statement Reformulation and Convergence

As described in Section 2.1 we aim to construct \( m \)-periodic exploration sequences \( u_\ell \) and \( v_\ell \) and generating functions \( f \) and \( g \) such that (2) with transition map (5) yields (4). Our first result restates the problem in terms of solving a system of nonlinear equations.
These two constructions are presented in the following two subsections. We start with a remark on \( T(W) \) and the convergence result of the proposed algorithms.

**Remark 1.** To get a sense of equation (14) and the role of \( T(W) \), partition \( T(W) \) as

\[
\begin{bmatrix}
T_{11}(W) & T_{12}(W) \\
T_{21}(W) & T_{22}(W)
\end{bmatrix},
\]

with \( T_{11}(W), T_{12}(W), T_{21}(W), T_{22}(W) \in \mathbb{R}^{n \times n} \). Note that \( T_{11}(W) \) is defined solely by \( \{ u_t \}_{t=0}^{m-1}, T_{22}(W) \) solely by \( \{ v_t \}_{t=0}^{m-1}, \) and \( T_{12}(W) \) and \( T_{21}(W) \) by both \( \{ u_t \}_{t=0}^{m-1} \) and \( \{ v_t \}_{t=0}^{m-1} \). Then (14) with (16) yields

\[
\frac{\partial f}{\partial f} T_{11} + \frac{\partial f}{\partial f} T_{12} + \frac{\partial g}{\partial f} T_{21} + \frac{\partial g}{\partial f} T_{22} = -I
\]

where the arguments \( f(x_0) \) of the maps \( f \) and \( g \) and their derivatives and \( W \) of \( f_{ij} \) with \( i,j \in \{1,2\} \) are omitted for the sake of readability. By plugging \( \{ u_t \}_{t=0}^{m-1} \) and \( \{ v_t \}_{t=0}^{m-1} \) from (9), with \( W_1 \) and \( W_2 \) for \( [a_1 \ a_2] = [1 \ 0] \) and \( [a_1 \ a_2] = [1/2 \ 1/2] \), respectively, into (13), one obtains

\[
T(W_1) = \begin{bmatrix}
-I & -I \\
I & 0
\end{bmatrix}, \quad \text{and} \quad T(W_2) = \begin{bmatrix}
0 & -I \\
I & 0
\end{bmatrix}.
\]

Hence, the left hand side of (17) translates into the terms in the curly brackets in (10) and (11), respectively. A geometric interpretation of \( T(W) \) is discussed in Section 4.2.

Due to property (4), for example, semi-global practical asymptotic convergence to the optimizer \( x^* \) can be established (see [21]):

**Theorem 2.** Let (A1) and (A2) hold. Assume that there exist generating functions \( f(J(x)) \) and \( g(J(x)) \) and an exploration sequence matrix \( W \) such that (14) and (15) are satisfied. Then, for all \( \delta_1, \delta_2 \in \mathbb{R}_{>0} \) with \( \delta_2 < \delta_1 \), there exist an \( h^* \in \mathbb{R}_{>0} \) and \( N(h) \in \mathbb{N} \), such that for all \( h \in \{ \tilde{h} \mid 0 < \tilde{h} < h^* \} \) and \( x_0 \in U_{x^*} \), it holds \( x_k \in U_{x^*} \) for all \( k \geq N(h) \).

The proof of Theorem 2 follows along the lines of the proof of [11, Theorem 2] by utilizing Lemma 3 in Appendix A and Theorem 1.

**Remark 2.** Theorem 2 is based on a constant step size \( h \). Applying a variable decreasing step size \( h_k \), but constant over a period of length \( m \), i.e., \( h_0 = h_1 = \cdots = h_{m-1}, h_m = h_{m+1} = \cdots = h_{2m-1} = \cdots \), with

\[
\sum_{p=0}^{\infty} h_{pm} = \infty, \quad \sum_{p=0}^{\infty} h_{pm}^2 < \infty,
\]

e.g. \( h_k = 1/((k/m)+1) \). (cf. Proposition 1 in [5]) lead to a semi-global asymptotic convergence result and a potential numerical performance improvement. Note that the requirement of periodically \( m \) constant steps preserves the \( O(\sqrt{h}) \)-order terms in (12) (cf. proof of Lemma 3).
3.2. Exploration Sequences

In this part we characterize the conditions under which there exists an exploration sequence matrix $W$ for a given $T_d$ such that $T(W) = T_d$ together with $W1 = 0$ are satisfied, hence, addressing Step 1) as stated above. The next lemma represents $T(W)$, i.e. (13), in combination with (15) in a more compact form.

**Remark 3.**

Either matrices $T_m$ defined (11), i.e. (13), in combination with (15) can be defined as $T_m = W P W^\top$, with $P \in \mathbb{R}^{m \times m}$ defined as

$$ P = \begin{bmatrix} c_1 & c_2 & \cdots & c_2 & 0 \\ a_2 & \ddots & \ddots & \vdots & \vdots \\ \vdots & \ddots & \ddots & c_2 & \vdots \\ a_2 & \cdots & a_2 & c_1 & 0 \\ 0 & \cdots & 0 & 0 & 0 \end{bmatrix} $$

where $c_1 = 2a_2 - (a_1 + a_2)^2$, $c_2 = a_2 - (a_1 + a_2)^2$, and $a_1, a_2$ defined in (5).

The proof of Lemma 1 is given in Appendix B.2. Consequently, when proceeding according to Step 1) and Step 2) described in the section above, the key equations for the design of the exploration sequences are

$$ WPW^\top = T_d \quad W1 = 0. $$

The following theorem, which provides a constructive design of the exploration sequence matrix $W$, is of central importance. It also provides structural insight in terms of obtaining lower bounds on the length (period) of the exploration sequence $m$, suitable choices of the parameters $a_1$ and $a_2$ and admissible structures for the desired target matrices $T_d$.

**Theorem 3.** Given $a_1, a_2$ and $T_d \in \mathbb{R}^{2n \times 2n}$. Suppose that either $T_d$ is normal, $(2a_2 - (a_1 + a_2)^2)(T_d + T_d^\top)$ positive definite, and Conjecture 1 (see below) is satisfied or that $T_d$ is skew-symmetric with $2a_2 - (a_1 + a_2)^2 = 0$. Then there exists a $m \geq \text{rk}(T_d) + 1$ such that $W \in \mathbb{R}^{2n \times m}$ satisfies the system of equations (22).

The role of Conjecture 1 in Theorem 3 is discussed in Remark 3.

**Conjecture 1.** Let the skew-symmetric matrix $C(m) \in \mathbb{R}^{m \times m}$ be defined as

$$ C(m) := A(m) + \epsilon(m + 1)B(m) \quad (23) $$

$$ A(m) := \begin{bmatrix} 0 & 1 & \cdots & 1 \\ -1 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & 1 \\ -1 & \cdots & -1 & 0 \end{bmatrix} \in \mathbb{R}^{m \times m}, $$

$$ B(m) := \begin{bmatrix} 1 & 0 & 2 & 4 & \cdots & 2(m - 1) \\ 0 & 1 & 0 & 2 & \cdots & 2(m - 2) \\ \vdots & \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & 1 \end{bmatrix} \in \mathbb{R}^{m \times m} \quad (24), (25) $$

with $\epsilon(m) = (m - 1)^{-1}(1 - m^{-1/2})$. Then for any $m \geq 2$, $C(m)$ and $C(m + 1)$ satisfy the eigenvalue interlacing property (cf. Lemma 4 in Appendix A).

$$ \omega_k^{m+1} > \omega_k^m > \omega_k^{m+1} \geq 0, \quad (26) $$

for $k = 1, \ldots, [m/2]$, where $\pm \omega_k^m$ are the eigenvalues of $C(m)$, with $\{\omega_k^m\}_{k=1}^m$ sorted in non-decreasing order in $k$ for $m$ fixed.

**Remark 3.** We verified numerically that Conjecture 1 is always true (we verified it up to dimension $m = 10000$, see Appendix A), but a proof is still lacking. Further notice, that $C(m)$ is part of the following equation:

$$ \tilde{P}(m) = (P - \epsilon(m)11^\top P + P11^\top) + \epsilon^2(m)11^\top P11^\top = \frac{1}{2}(a_1 + a_2)^2 - a_2)I + \frac{1}{2}(a_1 + a_2)^2C(m - 1) \quad (27) $$

with $P$ in (21) and $\epsilon(m)$ defined in Conjecture 1. Note that the interlacing property (26) holds also for $\tilde{P}(m)$, since it is arranged by a scaled unit matrix and the skew-symmetric matrix $C(m - 1)$ (cf. [22]). The interlacing property of $\tilde{P}(m)$ is utilized in the proof of Theorem 3.

The proof of Theorem 3 is constructive and presented in Appendix B.3, where in particular in (105), Conjecture 1 enters. A step-by-step construction of $W$ for a given $T_d$ is provided in Appendix C.1. Moreover we obtain as a corollary (which follows by the proof of Theorem 3):

**Corollary 1.** If $2a_2 - (a_1 + a_2)^2 = 0$ and $T_d$ skew-symmetric, then there always exists an $W \in \mathbb{R}^{2n \times m}$, with $m = \text{rk}(T_d) + 1$.

**Remark 4.** It is worthwhile to point out an interesting connection between the equations in (22) and nonlinear control theory, i.e. the controllability of the so-called non-holonomic integrator. Suppose $\{w_k\}_{k=0}^{m-1}$ is a solution of (22), then it can be verified by direct calculations (see also proof of Lemma 1 in Appendix B.2) that it is also a solution of the two point boundary value problem

$$ y_0 = 0, \quad Z_0 = 0, \quad y_m = 0, \quad Z_m = T_d $$

$$ y_{k+1} = y_k + w_k $$

$$ Z_{k+1} = Z_k + (a_1 + a_2)^2w_k y_k^\top + a_2 w_k w_k^\top \quad (28) $$
with \( k = 0, \ldots, m - 1 \), states \( y_k \in \mathbb{R}^{2n} \), \( z_k \in \mathbb{R}^{2n \times 2n} \), input \( w_k \in \mathbb{R}^{2n} \), and vice versa. In particular with \( W I = 0 \), i.e., \( w_{m-1} = - \sum_{i=0}^{m-2} w_i \), (28) translates into

\[
\begin{align*}
y_0 &= 0, \quad Z_0 = 0, \quad Z_{m-1} = T_d \\
y_{k+1} &= y_k + w_k \\
Z_{k+1} &= Z_k + a_2 w_k y_k^T + (a_2 - (a_1 + a_2)^2)y_k w_k^T + (2a_2 - (a_1 + a_2)^2)w_k w_k^T.
\end{align*}
\]

(29)

Considering now the case \([a_1 \ a_2] = [1/2 \ 1/2] \) shows that (29) is the state-transition of the generalized discrete-time nonholonomic integrator [23] with given initial and final states. Problem (28) with \([a_1 \ a_2] = [1 \ 0] \) has a similar structure. Hence, Theorem 3 provides an explicit solution to this state transition problem. Moreover, this viewpoint underlines the relationship to non-commutative maps and flows as indicated in Section 2.2 (Figure 2). Another, more geometric, interpretation of (22) is also provided in Section 4.2.

### 3.3. Gradient Generating Functions

This part addresses Step 2), i.e. solving the (functional) equation (14) for \( f, g \), and \( T_d \in \mathbb{R}^{2n \times 2n} \) with \( T(W) = T_d \). First, solutions \((T_d, f, g)\) for the parameter setting \(2a_2 - (a_1 + a_2)^2 = 0 \) and \( T_d \) skew-symmetric, then (14) is satisfied by the following triples \((T_d, f, g)\), where \( a, b \in \mathbb{R}_{>0} \) and \( c, \phi \in \mathbb{R} \):

- \( T_d = \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix}, \quad g(z) = -f(z) \int f(z)^{-2}dz, \quad f : \mathbb{R} \to \mathbb{R} \)

(30)

- \( T_d = \begin{bmatrix} aQ & -I \\ I & bQ \end{bmatrix}, \quad Q = -Q^T, \quad f(z) = a^{-1/2} \sin \left( \sqrt{ab}z + \phi \right), \quad g(z) = b^{-1/2} \cos \left( \sqrt{ab}z + \phi \right) \)

(31)

- \( T_d = \begin{bmatrix} aQ & -I \\ I & -bQ \end{bmatrix}, \quad Q = -Q^T, \quad f(z) = \pm a^{-1/2} \cosh \left( \sqrt{ab}z + \phi \right), \quad g(z) = \mp b^{-1/2} \sinh \left( \sqrt{ab}z + \phi \right) \)

(32)

- \( T_d = \begin{bmatrix} Q & -I \\ I & 0 \end{bmatrix}, \quad Q = -Q^T, \quad f(z) = \pm \sqrt{a}, \quad g(z) = \mp \frac{z}{\sqrt{a}} \)

(33)

- \( T_d = \begin{bmatrix} 0 & -I \\ I & Q \end{bmatrix}, \quad f(z) = \pm \frac{z}{\sqrt{a}}, \quad g(z) = \pm \frac{z}{\sqrt{a}} \)

(34)

- \( T_d = \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix}, \quad f(z) = \pm \frac{z}{\sqrt{a}}, \quad g(z) = \pm \frac{z}{\sqrt{a}} \)

(35)

- \( T_d = \begin{bmatrix} aQ & -I - cQ \\ I - cQ & bQ \end{bmatrix}, \quad Q = -Q^T, \quad f(z) = \sqrt{\frac{b}{ab - c^2}} \sin \left( \sqrt{ab - c^2}z + \phi \right), \quad g(z) = b^{-1/2} \cos \left( \sqrt{ab - c^2}z + \phi \right) \)

(36)

In addition, for each \( T_d \) in (30)-(36) there exists an \( W \), such that \( T(W) = T_d \) in (13). In (36), we require that \( a, b > c \).

**Remark 5.** Every pair \( f, g \) in (31)-(36) satisfy (30), hence, these generating functions are valid for the given \( T_d \) in (30), too. The advantage of the specified \( T_d \)’s are discussed in Section 4.2.

**Remark 6.** Consider the indefinite integral in (30). Let \( F : \mathbb{R}^n \to \mathbb{R} \) be an anti-derivative of \( f(z)^{-2} \). Then so is \( F + \tilde{c} \) for any \( \tilde{c} \in \mathbb{R} \). Set \( g(z) = -f(z)(F(z) + \tilde{c}) \). The constant \( \tilde{c} \) is chosen such that \( g'(z)f(z) - f'(z)g(z) = -1 \).

The proof of Theorem 4 is given in Appendix B.4. Solutions \((T_d, f, g)\) of (14) for the parameter setting \(2a_2 - (a_1 + a_2)^2 \neq 0 \) are presented next.

**Theorem 5.** Let \( T_d \in \mathbb{R}^{2n \times 2n} \) be normal and \( (2a_2 - (a_1 + a_2)^2)(T_d + T_d^T) \) be positive definite, then (14) is satisfied by the following triples \((T_d, f, g)\), where \( r : \mathbb{R} \to \mathbb{R}_{>0}, \quad a \in \mathbb{R} \setminus \{0\}, \quad b \in \mathbb{R}_{>0}, \) and \( \phi \in \mathbb{R} \):

- \( T_d = \begin{bmatrix} aI & -I \\ I & aI \end{bmatrix}, \quad a(2a_2 - (a_1 + a_2)^2) > 0, \quad f(z) = \sqrt{r(z)} \sin(\phi(z)), \quad g(z) = \sqrt{r(z)} \cos(\phi(z)), \quad \phi(z) = a \frac{1}{2} \ln(r(z)) + \int \frac{1}{r(z)}dz + \phi \)

(37)

- \( T_d = \begin{bmatrix} Q & -I \\ I & Q \end{bmatrix}, \quad (2a_2 - (a_1 + a_2)^2)(Q + Q^T) \) pos. def. and normal, \( f(z) = b^{-1/2} \sin (bz + \phi), \quad g(z) = b^{-1/2} \cos (bz + \phi) \)

(38)

In addition for every \( T_d \) in (37)-(38) there exists an \( W \), such that \( T(W) = T_d \) in (13).
The proof of Theorem 5 is given in Appendix B.5.

**Remark 7.** The list of triples \((T_d, f, g)\) in Theorem 4 is essentially exhaustive, save for some scaled version of the presented cases. A case by case study is presented in the proof of Theorem 4 in Appendix B.4. Whereas the list of triples \((T_d, f, g)\) in Theorem 5 is not exhaustive (cf. Appendix B.5).

Theorem 4 and Theorem 5 together with Theorem 3 solve (14) and (15) and thus ensure the existence of a exploration sequence matrix \(W\). Hence, a gradient descent step is approximated by the proposed algorithm (2) with transition maps (5).

**4. ALGORITHM, PARAMETERS AND NUMERICAL RESULTS**

In this section we present some numerical studies of the proposed class of algorithms. We carry out simulations and discuss how various choices of \(T_d\), of the singular values of \(W\), of the sequence length (period) \(m\), of the parameters \(\alpha_1, \alpha_2\) influence the qualitative behavior of the algorithm. Further, a numerical approach to construct the exploration sequences using nonlinear programming is presented.

We start by summarizing the proposed optimization algorithm and the involved parameters.

**4.1. Algorithm and Parameters**

The design parameters and functions involved in the proposed algorithm are

1. map parameters \(\alpha_1, \alpha_2 \in \mathbb{R}\) with \(\alpha_1 + \alpha_2 \neq 0\),
2. gradient generating functions \(f, g : \mathbb{R} \rightarrow \mathbb{R}\),
3. matrix \(T_d\) and exploration sequence matrix \(W\), in particular singular values \(\sigma_i, i = 1, \ldots, \text{rk}(T_d)\) of \(W\),
4. step size \(h > 0\).

Hence, algorithm (2) with (5) is defined in terms of \(W\) as follows:

Notice that \(Y(f(x_k))\) is a \(n \times 2n\) matrix. Moreover, if \(\alpha_2 = 0\), then line 8 and 9 in Algorithm 1 can be skipped.

In the following we discuss the influence of the design parameters on the algorithm’s behavior. Additionally, a set of parameters working well in generic situations, which can then be used as a starting point to obtain optimized parameters for a particular application, is provided.

1. **Map parameters \(\alpha_1, \alpha_2\).** The parameters weight \(Y(f(x_k))\) and \(Y(f(x_k))\) in Algorithm 1, respectively. In particular, they can be utilized to choose between a single-point \((\alpha_2 = 0)\) or a two-point algorithm. They are to be normalized according to \(\alpha_1 + \alpha_2 = 1\) and to tune according to the ratio of \(\alpha_1, \alpha_2\), while utilizing the step size \(h\) to tune the convergence speed. Moreover, the choice of \(\alpha_1, \alpha_2\) restricts the choice of \(T_d\) to be skew-symmetric for \(2\alpha_2 - (\alpha_1 + \alpha_2)^2 = 0\) and otherwise normal (cf. Theorem 4 and Theorem 5). In practice, the parameter sets we found providing the best performance were \([\alpha_1 \alpha_2] = [1 0]\) for the single-point and \([\alpha_1 \alpha_2] = [1/2 1/2]\) for the two-point gradient-approximation scheme.

2. **Generating functions \(f, g\).** The generating functions comprise a scaling of the objective evaluated at \(x_k\) and \(\hat{x}_k\) as stated in Algorithm 1. Various choices are presented in Theorem 4 and Theorem 5; depending on \(\alpha_1, \alpha_2\). Often we have chosen \(f, g\) as sinusoidal functions, since the algorithm showed a very stable behavior for that cases. Note that high function values of \(f, g\) or if \(f, g\) scale arbitrarily large with \(J(x_k)\), the algorithm performs large steps which may cause instabilities. In the case of bounded functions, such as sinusoidal functions, (arbitrarily) large steps sizes are avoided. Further, if \(f, g\) vanish at a minimum \(x^*\), asymptotic convergence to \(x^*\) (instead of practical convergence) has been observed in our studies.

3. **Exploration sequence matrix \(W\) and \(T_d\).** The exploration sequence matrix \(W\) depends on the choice of \(T_d\), specifically on the eigenvalues of \(T_d\). A step-by-step construction of \(W\) based on the algorithm parameters is presented in Appendix C.1. As explained in this construction, the singular values of \(W\) can be chosen (see Corollary 2 below), hence this degree of freedom can be used in the algorithm tuning. As shown in numerical examples below, smaller singular values lead to smoother trajectories, but more steps (larger \(m\)) are needed to perform one gradient approximation step. There exists a set of optimal singular values in the sense of minimal number of steps \(m\), which

**Algorithm 1.** Derivative-free optimization algorithm with non-commutative maps

1. **Input:** \(x_0, h, \alpha_1, \alpha_2, f(J(\cdot)), g(J(\cdot)), T_d\), \(\sigma_i (i = 1, \ldots, \text{rk}(T_d))\), stop criterion
2. Calculate \(W\) and \(m\) as described in Appendix C.1
3. \(k = 0\)
4. While stop criterion is not fulfilled do
5. \(\ell = k \mod (m) + 1\)
6. \(e_\ell = [0_\ell, 1, 0_{n-1-\ell}]^T\)
7. \(Y(J(x_k)) = [f(J(x_k))]I g(J(x_k))I\)
8. \(\hat{x}_k = x_k + \sqrt{\alpha_1}Y(J(x_k))W e_\ell\)
9. \(Y(J(\hat{x}_k)) = [f(J(\hat{x}_k))]I g(J(\hat{x}_k))I\)
10. \(x_{k+1} = x_k + \sqrt{\alpha_1}Y(J(x_k)) + \alpha_2 Y(J(\hat{x}_k))W e_\ell\)
11. \(k \leftarrow k + 1\)
12. End while
13. return \([x_0, x_1, \ldots]\)
is $m = \text{rk}(T_d) + 1$. Therewith, the choice of $T_d$ influences the lower bound on $m$ (see Corollary 3 below). Note that minimal sequence length $m$ does not always lead to the fastest convergence behaviour.

4. Step size $h$. The approximated gradient is scaled with the step size $h$, and hence, $h$ influences the speed of convergence, as well as the area of exploration around $x_k$. As stated in Theorem 2 there exists an upper bound on $h$ such that semi-global practical asymptotic convergence (if (A1) and (A2) holds) is ensured. In our numerical studies, $h$ is often chosen as $0.001 \leq h \leq 0.5$.

**Corollary 2.** In the case $2a_2 - (a_1 + a_2)^2 = 0$, the singular values $\sigma_{2\ell-1}, \sigma_{2\ell}, \ell = 1, \ldots, \lfloor \text{rk}(T_d)/2 \rfloor$, of $W$ can be chosen arbitrarily. Otherwise, the singular values of $W$ have to satisfy $\sigma_{2\ell-1} = \sigma_{2\ell}$ and

$$T_d = \begin{bmatrix} \text{diag}(\{\gamma_1, \ldots, \gamma_n\}) & -I \\ I & \text{diag}(\{\gamma_1, \ldots, \gamma_n\}) \end{bmatrix}, \quad (39)$$

with

$$\gamma_{\ell} = \left( a_2 - \frac{1}{2}(a_1 + a_2)^2 \right) \sigma_{2\ell-1}^2. \quad (40)$$

**Proof.** Following directly from the proof of Theorem 3 in Appendix B.3. Specifically, $T_d$ in (39) satisfies (38) and (40) corresponds to (102).

**Corollary 3.** The minimal number of steps to approximate a gradient according to (2) - (5) and using the $T_d$'s in Theorem 4 and Theorem 5 is $m = n + 1$.

**Proof.** Since the first $n$ rows of each $T_d$ in Theorem 4 and Theorem 5 are linearly independent, we know $\min\{\text{rk}(T_d)\} \geq n$. This implies with Theorem 3 that $m \geq n + 1$.

**Remark 8.** A gradient step is approximated using $m = n + 1$ steps for $T_d$ as specified in (31) and $Q$ with elements $\{q_{ij}\}_{ij=1}^{2n}$ such that

$$q_{ij} = \begin{cases} 1 & \text{if } i + j = 2n + 1, \ i > j \\ -1 & \text{if } i + j = 2n + 1, \ i < j \\ 0 & \text{else} \end{cases} \quad (41)$$

holds, while the singular values $\sigma_{2\ell-1}, \sigma_{2\ell}$ of $W$ satisfy (104) for $\ell = 1, \ldots, [n/2]$.

### 4.2. Numerical Results

In the following, various simulation results are presented to illustrate the influence of the algorithm parameters, i.e., matrix $T_d$, singular values $\sigma_k, k = 1, \ldots, r$, of $W$ and map parameters $a_1, a_2$. For the sake of visualization, we focus on examples with $n = 2$. An extensive benchmarking study, including the best choice of parameters for certain classes of the objective, is beyond the scope of this paper and carried out in ongoing and future work.

**Figure 3.** Generated areas of the exploration sequence $\{w_k\}_{k=0}^{m-1}$ in (9) for $T(W) \in \mathbb{R}^{2n \times 2n}$ as given in (42) for $n = 2$. Hence, $T(W)_{1,3} = T(W)_{2,4} = -1$, $T(W)_{3,1} = T(W)_{4,2} = 1$ and the rest 0. The filled green area ( ), have a area surface value of 1, the striped orange area ( ) of -1, and the rest of 0. The coordinates of each subplot are given by $x_{p,i}$ and $y_{q,i}$ defined in (44) for $p, q = 1, \ldots, 2n$.

$$T(W) = \begin{bmatrix} y_{1,i} & & & \\
 & y_{2,i} & & \\
 & & y_{3,i} & \\
 & & & y_{4,i} \\
\end{bmatrix}$$

The values of the components of $T(W)$ in (13) for $[a_1 \ a_2] = [1/2 \ 1/2]$, i.e.,

$$T(W)_{pq} = \sum_{i=0}^{m-1} \sum_{j=0}^{m-1} \frac{1}{2} e_p^TW_iw_i^Te_q + e_p^Tw_iw_j^Te_q, \quad (42)$$

with $p, q = 1, \ldots, 2n$, where the index $pq$ specifies the element of $T(W)$ in the $p$-th row and $q$-th column, can be interpreted as the projected areas spanned by the exploration sequences $\{e_p^Tw_i\}_{i=0}^{m-1}$, $\{e_q^Tw_i\}_{i=0}^{m-1}$. The net area $A_{pq}$ of an $n$-sided polygon with corner points $(x_{p,i}, y_{q,i}) \in \mathbb{R}^2$, $i = 0 \ldots n - 1$ and $p, q = 1, \ldots, 2n$, known as Shoelace or Gauss area formula [24] is obtained as a special case of Green’s Theorem and is given by

$$A_{pq} = \frac{1}{2} \sum_{i=0}^{n-1} (x_{p,i+1}y_{q,i} - x_{p,i}y_{q,i+1}) \quad (43)$$

with $x_{p,0} = x_{p,n} = 0$ and $y_{q,0} = y_{q,n} = 0$. In Lemma 6
In the second simulation study, we consider the same exploration sequence in (9) with \( w_k \) as specified in the proof of Corollary 3. The simulation results for two different choices of singular value pairs are depicted in Figure 4. On the one hand \( \sigma_1 = \sigma_2 = \sigma_3 = \sigma_4 = 1 \) yields \( m = 8 \) and on the other hand \( \sigma_1 = \sigma_2 = 1.5, \sigma_3 = \sigma_4 = 0.2 \) results in \( m = 21 \). In the latter case the areas with net area value \pm 1 have an elongated elliptical shape, which yield a small steady-state amplitude of \( \{ w_k \}_{k=0}^{m-1} \) and therefore a small steady-state amplitude since \( \sin(J(x^*)) = 0 \) and \( \cos(J(x^*)) = 1 \) (cf. (5)). Concluding, the amplitude of \( \{ w_k \}_{k=0}^{m-1} \) is proportional to \( \sigma_i \) with \( i = 1, \ldots, 2n \) for this choice of \( T_d \).

**Simulation 2.**

In the second simulation study, we consider the same setup as in Simulation 1, but choose \( T_d \) as in (31) with \( Q \) as specified in the proof of Corollary 3. The simulation results for two different choices of singular values pairs are depicted in Figure 5. On one hand \( \sigma_1 = \sigma_2 = 2 \) results in \( m = 4 \) and on the other hand \( \sigma_1 = \sigma_2 = 0.2 \) in \( m = 154 \). The singular values can be interpreted as a kind of...
energy measurement of the exploration sequence, and therefore in the latter case, \( m \) is much larger, but reveals a smoother behavior. Moreover, \( \sigma_1 \) influences the amplitude of \( \{e_{2i-1}w_k\}_{i=0}^{m-1} \) and \( \{e_{2i}w_k\}_{i=0}^{m-1} \) for \( i = 1, \ldots, n \) for the given choice of \( T_d \), compared to the previous simulation example. However, due to space limitations we omit the plots for \( \sigma_1 \neq \sigma_2 \).

Interestingly, as observed in Figure 4 and Figure 5 (d)+(h), the areas of \( T(W) \) for \( (i,j) \in \{(1,2), (2,1)\} \) and \( (i,j) \in \{(3,4), (4,3)\} \) have the same shape as the last \( m \) steps of \( x_k \).

**Simulation 3.**

Consider the same setup as in Simulation 1, but choosing \([a_1, a_2] = [1, 0]\) and \( T_d \) as described in (39). Choosing \( \sigma_1 = \sigma_2 = \sigma_3 = \sigma_4 = 1 \) results in the behavior depicted in Figure 6 (a)-(c), which is similar to the behavior from Figure 4 (a)-(d), where \( m = 8 \), too. On the one hand, the number of evaluations of the objective \( f \) is reduced by half when compared to Simulation 1. On the other hand, in this parameter setup, the choice of singular values is restricted to \( \sigma_1 = \sigma_2 \) and \( \sigma_3 = \sigma_4 \), hence, a behavior as in Figure 4 (e)-(h) can not be achieved. However, reducing \( \sigma_3 = \sigma_4 \) to 0.4 yields a scaling in the coordinate directions as illustrated in Figure 6 (d)-(f).

**Simulation 4.**

In this simulation scenario, we consider the cost function \( f(x) = \|x - [1 2] \|^2 + 0.5 \sin(10\pi x_2)^2 \), i.e., an objective with many local minima. We define \( f(J(x)) = \sin(J(x)) \), \( g(J(x)) = \cos(J(x)) \), \([a_1, a_2] = [1/2 1/2] \), \( h = 0.05 \), and \( x_0 = [1 2] \). The simulation results with \( T_d \) as in Simulation 2 and \( \sigma_1 = \sigma_2 = 1 \) are depicted in Figure 7. As motivated in the introduction, the proposed algorithm is able to overcome local minima and converges into a neighborhood of the global minimum. Due to the definition of the maps \( M_k^{\mathbb{R}^n} \), the gradient of \( f \) is gained by a procedure similar to numerical integration. It has been observed in simulations, that this procedure is numerically more stable than numerical differentiation (finite differences). In summary, this integrating behavior has the effect to even and flatten out local minima and noise respectively (cf. [7]).

**Simulation 5.**

One of the key advantages of derivative-free optimization is demonstrated, namely to deal with non-smooth objectives. To this end, in its ability to a simulation experiment,
the cost function is set to $f(x) = \|x\|$. We use the same algorithm parameters as in Simulation 2, i.e., $f(J(x)) = \sin(f(x))$, $g(J(x)) = \cos(f(x))$, $[\alpha_1 \ \alpha_2] = [1/2 \ 1/2]$, $h = 0.05$, and $x_0 = [1 \ 2]^T$ with $T_d$ as in (31), $Q$ specified in Corollary 3, and singular values $\sigma_1 = \sigma_2 = 0.4$. The algorithm’s behavior is depicted in Fig. 8. Since no first-order information (derivatives) needs to be computed, the algorithm is, as expected, converging to the local minima.

Remark 9. It is worth to mention that a very promising generating function class is

$$f(\mu) = \sqrt{2} \sin(\ln(\mu)), \ g(\mu) = \sqrt{2} \cos(\ln(\mu))$$

(45)

with $\mu \in \mathbb{R}_{>0}$, which belong to the setting of (30) and (37) (with some adaptions). Specifically, the Lie bracket between the generating functions results in $[f, g](\mu) = -\mu$, i.e., it holds $x_{m+k} = x_k - h\mu \nabla f(x_k) + O(h^{3/2})$. In this view, $\mu$ can be chosen large and $h$ small, hence, a large enough gradient step is executed while the oscillations can be kept small.

4.3. Exploration Sequences via Nonlinear Programming

Besides the construction of the exploration sequence as described in the proof of Theorem 3 in Appendix B.3 and the step-by-step construction of $W$ in Appendix C.1 one can compute a sequence with nonlinear programming by solving the constrained optimization problem

$$\min \ |\text{vec}(W)|_p^2$$

$$\text{s.t.} \ T(W) = T_d$$

(46)

Instead of the $p-$norm of $W \in \mathbb{R}^{2n \times m}$, one can in principle choose any other objective function, for example a weighted norm etc. In contrast to our constructive approach, the sequence length $m$ with $m \geq \text{rk}(T_d) + 1$ has to be specified in (46). An approximation of the lower bound of $m$ can be computed by following Step 4 of the step-by-step construction procedure for the exploration sequence matrix (see Appendix C.1) and choosing the singular values such that $m$ is minimal.

5. CONCLUSION

In this work, we proposed a novel class of derivative-free optimization algorithms. The idea was to approximate the gradient of the objective function by a $m$-fold composition of maps. These maps are defined by exploration sequences and generating functions. We provided a general framework for the construction of those ingredients. In particular, the construction of exploration sequences is
related to nonholonomic state-transition problems and is based on solving a system of quadratic equations, which we encountered by a singular value decomposition (see Theorem 3). The characterization of the generating functions was carried out by solving the functional equation (14) (see Theorem 4 and Theorem 5). Numerical simulations and a qualitative study of the dynamics of the algorithm were presented and the role of the algorithm parameters on the behavior of the algorithm was discussed. It turned out that the singular values of the exploration sequence matrix play a crucial role. Due to space limitations, we leave an extensive benchmarking study and comparisons with other derivative-free optimization algorithms for follow up work. The tuning of the algorithm parameters—which entails a choice of exploration sequences and generating functions, and balancing exploration and exploitation by proper step size rules or line search methods—requires systematic and intensive testing for suitable classes of objective functions, which is beyond the scope of this paper. Eventually, the tuning of the parameters can be approached, for example, by learning exploration sequences based on a training set of relevant objective functions using an hyperparameter optimization approach. Another future research direction is the extension of the proposed algorithm to extremum seeking problems (cf. [16]) for the two-point algorithmic scheme. Finally, designing exploration sequences plays a key role in our algorithms. This corresponds to the problem of finding sequences such that the first and second iterated summations, i.e. the one- and two-dimensional projected areas, have the values specified on the right hand sides of (22). To the best of our knowledge, a general and algorithmic characterization of solutions to this inverse problem (i.e. given signature values and find corresponding paths) is not known and in our opinion it is an interesting mathematical research question by its own [26].

A. Preliminary Lemmas

Lemma 2. Let \( a \in C^2(\mathbb{R}^n; \mathbb{R}), b \in C^0(\mathbb{R}^p; \mathbb{R}) \), and \( h \in \mathbb{R}_{\geq 0} \). Then for any compact convex set \( Z \subseteq \mathbb{R}^n \) and any compact set \( Y \subseteq \mathbb{R}^p \) there exist a \( R \in C^0(\mathbb{R}^n \times \mathbb{R}^p \times \mathbb{R}_{\geq 0}; \mathbb{R}) \) and a \( M \in \mathbb{R}_{\geq 0} \) such that for all \( z \), \( z + \theta h b(y) \in Z \) and \( y \in Y \) we have

\[
a(z + \theta h b(y)) = a(z) + h \frac{\partial a}{\partial z}(z) \top b(y) + R(z, y; h^2)
\]  

(47)

with \( |R(z, y; h^2)| \leq Mh^2 \), i.e., \( \lim_{h \to 0} R(z, y; h^2) = 0 \).

Proof. Equation (47) is obtained by applying Taylor’s theorem [27, Theorem 5.15, p. 110] up to degree two, thus, there exists a \( \theta \in [0, 1] \) such that

\[
a(z + \theta h b(y)) = a(z) + h \frac{\partial a}{\partial z}(z) \top b(y) + \frac{h^2}{2} b(y) \top \frac{\partial^2 a}{\partial z^2}(\bar{x}) b(y)
\]  

(48)

holds with \( \bar{x} = z + \theta h b(y) \). The term

\[
R(z, y; h^2) = h^2 b(y) \top \frac{\partial^2 a}{\partial z^2}(\bar{x}) b(y)
\]  

(49)

is the Lagrange remainder where \( \frac{\partial^2 a}{\partial z^2}(\cdot) \) is the Hessian of \( a(\cdot) \). Since \( Z \) and \( Y \) are compact and \( b \in C^0(\mathbb{R}^p; \mathbb{R}) \) there exists a \( M_b \in \mathbb{R}_{\geq 0} \) such that

\[
\|b(y)\|_2 \leq M_b, \quad y \in Y
\]  

(50)

holds. Furthermore, since \( Z \) is convex and compact and \( a \in C^2(\mathbb{R}^n; \mathbb{R}) \) there exists a \( M_a \in \mathbb{R}_{\geq 0} \) such that

\[
\|\frac{\partial^2 a}{\partial z^2}(\bar{x})\|_2 \leq M_a, \quad \bar{x} \in Z.
\]  

(51)

Finally, \( |R(z, y; h^2)| \leq Mh^2 \) with \( M = M_b^2 M_a \).

Lemma 3. Let Assumption (A1) hold true. Moreover, let \( \mathcal{X} \subseteq \mathbb{R}^n \) and \( \mathcal{J} \subseteq \mathbb{R} \) be compact convex sets, and \( m \in \mathbb{N}_{\geq 1} \). Then there exist a function \( R_{k+m-1} : \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}_{\geq 0} \to \mathbb{R}^n \) and a constant \( M_{k+m-1} \in \mathbb{R}_{\geq 0} \) such that for any iterates \( x_k, \ldots, x_{k+m} \) of the algorithm (2) with maps in (5), \( x_k, x_{k+1} + \sqrt{h}s_k(J(x_k)) \in \mathcal{X} \), and \( f(x_k), f(x_k + \sqrt{h}s_k(J(x_k))) \in \mathcal{J} \) for \( t = k, \ldots, k + m \), and we have

\[
x_{k+m} = x_k + \sqrt{h}(a_1 + a_2) \sum_{i=k}^{k+m-1} s_i(J(x_k))
\]  

\[
+ h(a_1 + a_2)^2 \sum_{i=k}^{k+m-1} \sum_{j=k}^{i-1} \frac{\partial s_i}{\partial f}(J(x_k))s_j(J(x_k)) \top \nabla J(x_k)
\]  

\[
+ h(a_1 + a_2)^2 \sum_{i=k}^{k+m-1} \sum_{j=k}^{i-1} \frac{\partial s_i}{\partial f}(J(x_k))s_j(J(x_k)) \top \nabla J(x_k)
\]  

\[
+ R_{m-1}(x_k, J(x_k); h^{3/2}),
\]  

(52)

with \( \|R_{k+m-1}(x_k, J(x_k); h^{3/2})\|_2 \leq M_{k+m-1} h^{3/2} \), i.e., \( R_{k+m-1}(x_k, J(x_k); h^{3/2}) = O(h^{3/2}) \).

Proof. W.l.o.g we set \( k = 0 \), i.e., we show by induction that the \( m \)-step evolution of (2) with transition map (5) is give by (52) with \( k = 0 \). Similarly to \( R(\cdot, \cdot, \cdot) \) in (47), we introduce the following notation of the Taylor remainder (T.R.) terms for \( k = 0, \ldots, m - 1 \):

- \( R_{J,k}^J(\cdot, \cdot, h) \) of T.R. of \( J(x_k) \)
- \( R_{s,k}^J(\cdot, \cdot, h) \) of T.R. of \( s_k(J(x_k)) \)
- \( R_{J,k}^s_J(\cdot, \cdot, h) \) of T.R. of \( J(x_k + \sqrt{h}s_k(J(x_k))) \)
- \( R_{s,k}^s_J(\cdot, \cdot, h) \) of T.R. of \( s_k(J(x_k + \sqrt{h}s_k(J(x_k)))) \)

and aggregated remainders with terms of order \( h \) or \( h^{3/2} \) and higher for \( k = 0, \ldots, m - 1 \):

- \( R^J(\cdot, \cdot, h^{3/2}) \) of \( x_k \)
- \( R_{J,k}^J(\cdot, \cdot, h) \) of \( J(x_k) \)
- \( R_{s,k}^J(\cdot, \cdot, h) \) of \( s_k(J(x_k)) \)
- \( R_{J,k}^s_J(\cdot, \cdot, h) \) of \( J(x_k + \sqrt{h}s_k(J(x_k))) \)
- \( R_{s,k}^s_J(\cdot, \cdot, h) \) of \( s_k(J(x_k + \sqrt{h}s_k(J(x_k)))) \)

Step 1: Basis. Consider the first step of (2) with (5), i.e,

\[
x_1 = x_0 + \sqrt{h}a_{150}(J(x_0))
\]  

\[
+ \sqrt{h}a_{250}(J(x_0 + \sqrt{h}s_0(J(x_0))))
\]  

\[
= x_0 + \sqrt{h}(a_1 + a_2)s_0(J(x_0))
\]  

\[
+ h(a_1 + a_2)^2 \frac{\partial s_0}{\partial f}(J(x_0))s_0(J(x_0)) \top \nabla J(x_0)
\]  

\[
+ R_0(x_0, J(x_0); h^{3/2})
\]  

(53)

with \( R_0 : \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}_{\geq 0} \to \mathbb{R}^n \). In the above equation, Lemma 2 is applied twice. First, for \( J(x_0 + \sqrt{h}s_0(J(x_0))) \)
where \( a(\cdot) := f(\cdot), b(\cdot) := s_0(\cdot), z := x_0, \) and \( y := J(x_0) \) in Lemma 2 are chosen such that \( R_{j,0}^{+}(\cdot; h) \) as in (49) exists, i.e.,
\[
J(x_0 + \sqrt{h}s_0(J(x_0))) = J(x_0) + \sqrt{h}s_0(J(x_0))^\top \nabla J(x_0) + R_{j,0}^{+}(x_0, J(x_0); h)
\]
with \( R_{j,0}^{+} : \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}_{\geq 0} \rightarrow \mathbb{R} \). Second, for \( s_0(J(x_0) + \sqrt{h}s_0(J(x_0)))) \) where \( a(\cdot) := f(\cdot) \) and \( a(\cdot) := g(\cdot), \)
\( b(x_0, J(x_0)) = s_0(J(x_0))^\top \nabla J(x_0) + R_{j,0}^{+}(x_0, J(x_0); h), \)
\( z := J(x_0), \) and \( y = [x_0^\top J(x_0)]^\top \) in Lemma 2 are chosen such that a \( R_{s,0}^{+}(\cdot; \cdot; h) \) as in (49) exists with given bounds on \( u_0 \) and \( v_0, i.e.,
\[
s_0(J(x_0) + \sqrt{h}s_0(J(x_0)))) = s_0(J(x_0)) + \sqrt{h}s_0(J(x_0))^\top \nabla J(x_0) + R_{s,0}^{+}(x_0, J(x_0); h)
\]
and we can obtain that \( R_0(x_0, J(x_0); h^{3/2}) = O(h^{3/2}) \), thus, (53) is (52) for \( k = 0 \) and \( m = 1 \).

**Step 2: Inductive Step.** Assume that (52) holds for \( x_{m-1} \), i.e., that the evolution of \( x_k \) for \( k = 0, \ldots, m-1 \) reads
\[
x_{m-1} = x_0 + \sqrt{h}(a_1 + a_2) \sum_{i=0}^{m-2} s_i(J(x_0)) + h(a_1 + a_2)^2 \sum_{i=0}^{m-2} \sum_{j=0}^{m-2-i} \frac{\partial s_j}{\partial J}(J(x_0)) s_i(J(x_0))^\top \nabla J(x_0)
\]
and there exists a \( M_{m-2} \in \mathbb{R}_{\geq 0} \) such that \( ||R_{m-2}(x_0, J(x_0); h^{3/2})||_2 \leq M_{m-2}h^{3/2} \). Next we consider the \( m \)-th step of (2) with (5), i.e.,
\[
x_m = x_{m-1} + \sqrt{h}x_{m-1}(x_0, J(x_0)) + \sqrt{h}x_{m-2}s_{m-1}(15)
\]
Again, as in Step 1, we apply Lemma 2 several times. First for \( J(x_{m-1}) \) where \( a(\cdot) := f(\cdot), b(x_0, J(x_0)) = h^{3/2}(r.h.s. of (59) - x_0), z := x_0, \) and \( y = [x_0^\top J(x_0)]^\top \) in Lemma 2 are chosen such that a \( R_{j,m-1}(\cdot; \cdot; h) \) as in (49) exists, i.e.,
\[
J(x_{m-1}) = J(r.h.s. of (59))
\]
(52) holds for \( x_{m-1} \), i.e., that the evolution of \( x_k \) for \( k = 0, \ldots, m-1 \) reads
\[
x_{m-1} = x_0 + \sqrt{h}(a_1 + a_2) \sum_{i=0}^{m-2} s_i(J(x_0)) + h(a_1 + a_2)^2 \sum_{i=0}^{m-2} \sum_{j=0}^{m-2-i} \frac{\partial s_j}{\partial J}(J(x_0)) s_i(J(x_0))^\top \nabla J(x_0)
\]
and we can obtain that \( R_0(x_0, J(x_0); h^{3/2}) = O(h^{3/2}) \), thus, (53) is (52) for \( k = 0 \) and \( m = 1 \).

**Step 2: Inductive Step.** Assume that (52) holds for \( x_{m-1} \), i.e., that the evolution of \( x_k \) for \( k = 0, \ldots, m-1 \) reads
\[
x_{m-1} = x_0 + \sqrt{h}(a_1 + a_2) \sum_{i=0}^{m-2} s_i(J(x_0)) + h(a_1 + a_2)^2 \sum_{i=0}^{m-2} \sum_{j=0}^{m-2-i} \frac{\partial s_j}{\partial J}(J(x_0)) s_i(J(x_0))^\top \nabla J(x_0)
\]
and there exists a \( M_{m-2} \in \mathbb{R}_{\geq 0} \) such that \( ||R_{m-2}(x_0, J(x_0); h^{3/2})||_2 \leq M_{m-2}h^{3/2} \). Next we consider the \( m \)-th step of (2) with (5), i.e.,
\[
x_m = x_{m-1} + \sqrt{h}x_{m-1}(x_0, J(x_0)) + \sqrt{h}x_{m-2}s_{m-1}(15)
\]
Again, as in Step 1, we apply Lemma 2 several times. First for \( J(x_{m-1}) \) where \( a(\cdot) := f(\cdot), b(x_0, J(x_0)) = h^{3/2}(r.h.s. of (59) - x_0), z := x_0, \) and \( y = [x_0^\top J(x_0)]^\top \) in Lemma 2 are chosen such that a \( R_{j,m-1}(\cdot; \cdot; h) \) as in (49) exists, i.e.,
\[
J(x_{m-1}) = J(r.h.s. of (59))
\]
a $R_{s,m-1}(\cdot; \cdot; h)$ as in (49) exists, i.e.,

$$s_{m-1}(J(x_{m-1})) = s_{m-1}(\text{rhs. of } (61))$$

(Lemma 2) \[= s_{m-1}(J(x_0)) + \sqrt{n}(\alpha_1 + \alpha_2) \times \sum_{i=0}^{m-2} \frac{\partial s_{m-1}}{\partial f}(J(x_0))s_i(J(x_0)) \top \nabla J(x_0) + \bar{R}_{s,m-1}(x_0, J(x_0); h)](63)

with $\bar{R}_{s,m-1} : \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^n$ where

$\bar{R}_{s,m-1}(x_0, J(x_0); h) = \frac{\partial s_{m-1}}{\partial f}(J(x_0))\bar{R}_{f,m-1}(x_0, J(x_0); h)$

+ $R_{s,m-1}(x_0, J(x_0); h) (64)$

with $R_{s,m-1} : \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^n$. Thirdly, Lemma 2 is applied on $J(x_{m-1} + \sqrt{n}s_{m-1}(J(x_{m-1})))$ where $a(\cdot) := f(\cdot), b(x_0, J(x_0)) = h^{-1/2}(\text{rhs. of } (59) - x_0) + \sqrt{n}(\text{rhs. of } (63)), z := x_0, and y = [x_0 \top J(x_0)] \top$ in Lemma 2 are chosen such that a $R_{f,m-1}(\cdot; \cdot; h)$ as in (49) exists, i.e.,

$J(x_{m-1} + \sqrt{n}s_{m-1}(J(x_{m-1}))))$

$= f(\text{rhs. of } (59) + \sqrt{n}(\text{rhs. of } (63)))$

(Lemma 2) \[= f(x_0) + \sqrt{n}(\alpha_1 + \alpha_2) \sum_{i=0}^{m-2} s_i(J(x_0)) \top \nabla J(x_0) + \sqrt{n}s_{m-1}(J(x_0)) \top \nabla J(x_0) + \bar{R}_{f,m-1}(x_0, J(x_0); h) (65)

with $\bar{R}_{f,m-1} : \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}$ where

$\bar{R}_{f,m-1}(x_0, J(x_0); h) = h \nabla_j f(x_0) (\alpha_1 + \alpha_2) \sum_{i=0}^{m-2} s_i(J(x_0)) \top \nabla J(x_0) + \alpha_1 + \alpha_2 \sum_{i=0}^{m-2} s_i(J(x_0)) \top \nabla J(x_0) + R_{m-2}(x_0, J(x_0); h^{3/2}) + \sqrt{n}\bar{R}_{s,m-1}(x_0, J(x_0); h) + \bar{R}_{f,m-1}(x_0, J(x_0); h) (66)$

with $R_{f,m-1} : \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}$. Lastly, Lemma 2 is applied on $s_{m-1}(J(x_{m-1} + \sqrt{n}s_{m-1}(J(x_{m-1}))))$ where $a(\cdot) := s_{m-1}(\cdot), b(x_0, J(x_0)) = h^{-1/2}(\text{rhs. of } (65) - J(x_0)), z := J(x_0), and y = [x_0 \top f(x_0)] \top$ in Lemma 2 are chosen such that a $R_{s,m-1}(\cdot; \cdot; h)$ as in (49) exists, i.e.,

$s_{m-1}(J(x_{m-1} + \sqrt{n}s_{m-1}(J(x_{m-1}))))$

$= s_{m-1}(\text{rhs. of } (65))$

(Lemma 2) \[= s_{m-1}(J(x_0)) + \sqrt{n}(\alpha_1 + \alpha_2) \sum_{i=0}^{m-2} s_i(J(x_0)) \top \nabla J(x_0) + \sqrt{n}\nabla s_{m-1}(J(x_0))s_{m-1}(J(x_0)) \top \nabla J(x_0) + \bar{R}_{s,m-1}(x_0, J(x_0); h) (67)

with $\bar{R}_{s,m-1} : \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}$ where

$\bar{R}_{s,m-1}(x_0, J(x_0); h) = \frac{\partial s_{m-1}}{\partial f}(J(x_0))\bar{R}_{f,m-1}(x_0, J(x_0); h)$

+ $R_{s,m-1}(x_0, J(x_0); h) (68)$

with $R_{f,m-1} : \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}$. Then with the same arguments as in Step 1, namely by assumption $J \in C^2(\mathbb{R}^2; \mathbb{R})$ (see Assumption (A1)) for every $k = 0, \ldots, m - 1$, $s_k \in C^2(\mathbb{R}; \mathbb{R}^n)$ (see Assumption (A1)), $x_k, x_k + \sqrt{n}s_k(J(x_k)) \in \mathcal{X}$, and $J(x_k), J(x_k + \sqrt{n}s_k(J(x_k))) \in \mathcal{J}$, thus, there exist $\bar{M}_{f,m-1}, \bar{M}_{s,m-1}, \bar{M}_{f,m-1}^+, \bar{M}_{s,m-1}^+ \in \mathbb{R}_{\geq 0}$ such that $|R_{f,m-1}(x_0, J(x_0); h)| \leq \bar{M}_{f,m-1}h$ and so on. Note that $\bar{M}_{f,m-1}$ is derived by (62) as

$\bar{M}_{f,m-1} = L_f \left( (\alpha_1 + \alpha_2)^2 \sum_{i=0}^{m-2} s_i(J(x_0)) \top \nabla J(x_0) + \sqrt{n}\bar{M}_{m-2} + \bar{M}_{f,m-1} \right)$

(69)

with $L_f, K_{s,i}, L_{s,i}, M_m \in \mathbb{R}_{\geq 0}$, where $\|\nabla J(x_0)\|_2 \leq L_f, \|\nabla^2 s_i(J(x_0))\|_2 \leq K_{s,i}, \|\bar{a}(J(x_0))\| \leq L_{s,i},$ and $|R_{m-2}(x_0, J(x_0); h^{3/2})| \leq M_{m-2}h^{3/2}$. Additionally, by Lemma 2 there exists a $\bar{M}_{s,m-1} \in \mathbb{R}_{\geq 0}$ such that $|R_{s,m-1}(x_0, J(x_0); h)| \leq \bar{M}_{s,m-1}h$. The constants $\bar{M}_{s,m-1}, \bar{M}_{f,m-1}^+, \bar{M}_{s,m-1}^+$ are derived in the same manner via (64), (66), and (68), respectively. Finally, plugging (63) and (67) in (60) yields (52) with $k = 0$ and

$R_{m-2}(x_0, J(x_0); h^{3/2}) = R_{m-2}(x_0, J(x_0); h^{3/2})$

+ $\sqrt{n}\alpha_1 R_{s,m-1}(x_0, J(x_0); h)$

+ $\sqrt{n}\alpha_2 R_{s,m-1}^+(x_0, J(x_0); h)$

(70)

where,

$\|R_{m-2}(x_0, J(x_0); h^{3/2})\|_2 \leq M_{m-2}h^{3/2}$

$\bar{M}_{s,m-1} \in \mathbb{R}_{\geq 0}$

:= $\bar{M}_{s,m-1} + \alpha_1 \bar{M}_{s,m-1}^+ h^{3/2}$.

(71)
The following two lemmas state the sufficient part of Cauchy's interlacing inequalities [28] for real skew-symmetric matrices. Hence, the imaginary part of the eigenvalues of the principal submatrix can be chosen w.r.t. certain inequalities depending on the eigenvalues of the given skew-symmetric matrix.

**Lemma 4.** Let \( C \in \mathbb{R}^{p \times p} \) be a skew-symmetric matrix with eigenvalues \( \pm \eta_k, \eta_k \in \mathbb{R}_{\geq 0}, k = 1, \ldots, \lfloor p/2 \rfloor \) and let \( \omega_{\ell} \in \mathbb{R}_{\geq 0}, \, \ell = 1, \ldots, \lfloor p/2 \rfloor - 1 \) such that the inequality

\[
\eta_1 \geq \omega_1 \geq \eta_2 \geq \omega_2 \cdots \geq \eta_{\lfloor p/2 \rfloor - 1} \geq \omega_{\lfloor p/2 \rfloor - 1} \geq \eta_{\lfloor p/2 \rfloor} \geq 0, \quad (72)
\]

is satisfied. Then there exists an unitary matrix \( \Theta \in \mathbb{R}^{p \times p} \) such that \( Q \in \mathbb{R}^{(p-1) \times (p-1)} \) is a principal submatrix of \( \Theta^T C \Theta \) with eigenvalues \( \pm \omega_{\ell} \).

For a proof, we refer to [29].

**Lemma 5.** Let \( C \in \mathbb{R}^{p \times p} \) be a skew-symmetric matrix with eigenvalues \( \pm \eta_k, \eta_k \in \mathbb{R}_{\geq 0}, \, \ell = 1, \ldots, p \), arranged according to

\[
\eta_1 \geq \eta_2 \geq \ldots \geq \eta_{\lfloor p/2 \rfloor} \geq 0. \quad (73)
\]

Then for \( \omega_1 \geq \omega_2 \geq \ldots \geq \omega_r \) with \( \omega_k \in \mathbb{R}_{\geq 0} \) such that

\[
\eta_k \geq \omega_k \geq \eta_{\lfloor p/2 \rfloor - r + k}, \quad (74)
\]

there exists an unitary matrix \( \Theta \in \mathbb{R}^{p \times p} \) such that \( Q \in \mathbb{R}^{(2r) \times (2r)} \) is a principal submatrix of \( \Theta^T C \Theta \) with eigenvalues \( \pm \omega_{\ell} \), \( \ell = 1, \ldots, r \).

**Proof.** Applying Lemma 4 \( \lfloor p/2 \rfloor - r \) times, yields the result, similar to the proof of [30, Theorem 1].

---

**Numerical validation of Conjecture 1**

Due to the dependency of \( C(m) \) on \( m \) in (23), the interlacing lemmas, see Lemma 4 and Lemma 5, are not applicable, since the entries of \( C(m) \) change with dimension due to \( e(m) \). We verified numerically that the interlacing property (26) holds for all \( m \leq 10000 \). The corresponding Matlab code is available in the ancillary file folder on Arxiv. Moreover, in Figure 9 the interlacing property for \( 4 \leq m \leq 10 \) is visualized.

![Figure 9. Illustration of the absolute value of the complex conjugated eigenvalues \( \pm \omega_{k} \) of \( \Theta \) in (27) w.r.t. \( m \) for \( k = 1, \ldots, \lfloor m/2 \rfloor \). The interlacing property (26) is apparent and visualized by the arrows, mapping the eigenvalues to the next lower dimension.](image)

Note that \( m \) acts as the exploration sequences’ lengths as introduced in (3) and (5), where in the worst case \( m = 4n \) (cf. (9)). This implies the property holds for sure for \( n \leq 2500 \) dimensional problems, which is a very high-dimensional problem for derivative-free algorithms.

**Lemma 6.** Let \( W \) such that \( W \mathbf{1} = 0 \) be given and \( e T(W) \) be as in (12) with \( [\alpha_1 \alpha_2] = [1/2 \, 1/2] \). Then the value in the \( p \)-th row and \( q \)-th column of \( T(W) \) is equivalent to the net area (cf. Gauss area formula in [24]) of the \( n \)-sided polygon in the \( e_p - e_q \) plane with corner points

\[
\mathbf{x}_{p,i} = \sum_{k=0}^{i-1} e_p^T w_{k}, \quad \mathbf{y}_{q,i} = \sum_{k=0}^{i-1} e_q^T w_{k} \quad (75)
\]

for \( i = 0, \ldots, m-1 \) and \( p,q = 1, \ldots, 2n \), where \( x_{p,0} = 0 \) and \( y_{q,0} = 0 \).

**Proof.** The entry in the \( p \)-th row and \( q \)-th column of the matrix \( T(W) \) in (12) with \( [\alpha_1 \alpha_2] = [1/2 \, 1/2] \) is given by

\[
T(W)_{pq} = \sum_{i=0}^{m-1} \frac{1}{2} e_p^T w_i e_q + \sum_{i=0}^{m-1} e_p^T w_i e_q. \quad (76)
\]

Condition \( W \mathbf{1} = 0 \) implies \( w_{m-1} = - \sum_{i=0}^{m-1} w_i \) such that we have

\[
T(W) = \sum_{i=0}^{m-2} \left( \frac{1}{2} w_i w_i^T + \sum_{j=0}^{i-1} w_j w_j^T \right) + \frac{1}{2} w_{m-1} w_{m-1}^T
\]

\[
+ \sum_{j=0}^{m-2} w_{m-1} w_j^T
\]

\[
= \sum_{i=0}^{m-2} \left( \frac{1}{2} w_i w_i^T + \sum_{j=0}^{i-1} w_j w_j^T + \frac{1}{2} \sum_{j=0}^{m-2} w_j w_j^T \right)
\]

\[
- \sum_{j=0}^{m-2} w_i w_j^T
\]

\[
= \frac{1}{2} \sum_{i=0}^{m-2} \left( w_i w_i^T + \sum_{j=0}^{i-1} w_j w_j^T - \sum_{j=i}^{m-2} w_j w_j^T \right)
\]

\[
= \frac{1}{2} \sum_{i=0}^{n-2} \left( \sum_{j=0}^{i-1} w_j w_j^T - \frac{1}{2} \sum_{j=i+1}^{m-2} w_j w_j^T \right)
\]

\[
= \frac{1}{2} \sum_{i=0}^{m-2} \sum_{j=0}^{i-1} (w_i w_j^T - w_j w_i^T), \quad (77)
\]
where the last line of (77) is obtained by the reindexing
\[
\begin{align*}
\sum_{i=0}^{m-2} \sum_{j=i+1}^{m-2} w_i w_j^\top &= w_0 (w_1 + w_2 + \cdots + w_{m-2})^\top \\
&\quad + w_1 (w_2 + w_3 + \cdots + w_{m-2})^\top \\
&\quad + \cdots \\
&\quad + w_{m-3} w_{m-2}^\top = \sum_{i=0}^{m-2-i} \sum_{j=0}^{m-2-i} w_i w_j^\top. (78)
\end{align*}
\]
Hence, it follows for the entry of \( T(W) \) in the \( p \)-th row and \( q \)-th column
\[
T(W)_{pq} = \frac{1}{2} \sum_{i=0}^{m-2-i} \sum_{j=0}^{m-2-i} e_p^\top w_i w_j^\top e_q - e_p^\top w_i w_j^\top e_q. (79)
\]
On the other hand, the net area formula of a \( n \)-sided polygon with corner points \( \{x_{p,i}, y_{q,i}\}_{i=1}^n \) is given as
\[
A_{pq} = \frac{1}{2} \sum_{i=0}^{m-1} x_{p,i+1} y_{q,i} - x_{p,i} y_{q,i+1}. (80)
\]
Plugging (75) with \( n = m \) in (80) and using \( \sum_{i=0}^{m-1} w_i = 0 \) yields
\[
A_{pq} = \frac{1}{2} \sum_{i=0}^{m-1} \left( \sum_{j=0}^{i} e_p^\top w_j \right) \left( \sum_{j=0}^{i-1} w_j^\top e_q \right) - \left( \sum_{j=0}^{i} e_p^\top w_j \right) \left( \sum_{j=0}^{i-1} w_j^\top e_q \right) - \left( \sum_{j=0}^{i} e_p^\top w_j \right) w_i^\top e_q. (81)
\]
Consequently, \( A_{pq} = T(W)_{pq} \) holds. \( \Box \)

**B. PROOFS**

**B.1. Proof Theorem 1**

The proof utilizes the result of Lemma 3. Consider the \( m \)-th step of the evolution of (2) represented by (52) with transition map (5). Let \( w_\ell = [u_\ell^\top v_\ell^\top]^\top \) for \( \ell = k, \ldots, k + m - 1 \) and
\[
Y(f(z), g(z)) = \begin{bmatrix} f(z) I \\
g(z) I \end{bmatrix}, \quad \tilde{Y}(f(z), g(z)) = \begin{bmatrix} \frac{\partial f}{\partial z} (z) I & \frac{\partial g}{\partial z} (z) I \end{bmatrix}. (82, 83)
\]
Then plugging \( \{w_i\}_{i=k}^{k+m-1} \), \( Y(f(J(x_k)), g(J(x_k))) \) and \( \tilde{Y}(f(J(x_k)), g(J(x_k))) \) into (52) yields
\[
x_{k+m} = x_k + \sqrt{h} (\alpha_1 + \alpha_2) Y(f(J(x_k)), g(J(x_k))) \sum_{i=k}^{k+m-1} w_i \\
+ h \tilde{Y}(f(J(x_k)), g(J(x_k))) \left\{ \sum_{i=k}^{k+m-1} (\alpha_2 w_i w_i^\top) \\
+ (\alpha_1 + \alpha_2)^2 \sum_{i=k}^{m-1} w_i w_i^\top \right\} Y(f(J(x_k)), g(J(x_k)))^\top \\
\times \nabla J(x_k) + O(h^{3/2}). (84)
\]
The term in the curly brackets in (84) yields \( T(W) \) in (13) and therefore (12) is recovered. \( \Box \)

**B.2. Proof Lemma 1**

Condition (15) implies
\[
w_{m-1} = - \sum_{i=0}^{m-2} w_i. (85)
\]
Plugging (85) into (13) yields
\[
T(W) = \sum_{i=0}^{m-2} \left( \alpha_2 w_i w_i^\top + (\alpha_1 + \alpha_2)^2 \sum_{j=0}^{i-1} w_j w_j^\top \right) \\
+ \alpha_2 w_{m-1} w_{m-1}^\top + (\alpha_1 + \alpha_2)^2 \sum_{i=0}^{m-2} w_i w_i^\top \\
= \alpha_2 \sum_{i=0}^{m-2} \left( w_i w_i^\top + \sum_{j=0}^{m-2} w_j w_j^\top \right) + (\alpha_1 + \alpha_2)^2 \sum_{i=0}^{m-2} \left( \sum_{j=0}^{m-2} w_i w_j - \sum_{j=0}^{m-2} w_j w_j \right) \\
= \alpha_2 \sum_{i=0}^{m-2} \left( w_i w_i^\top + \sum_{j=0}^{m-2} w_j w_j^\top \right) \\
- \frac{1}{2} \left( \sum_{i=0}^{m-2} \sum_{j=0}^{m-2} w_i w_j \right) + \frac{1}{2} \left( \sum_{i=0}^{m-2} \sum_{j=0}^{m-2} w_i w_j \right) \quad (86)
\]
Hence, \( P \) in (21) is recovered. \( \Box \)
Consider (22) and the singular value decomposition of the exploration sequence matrix

\[ W = U \Sigma \begin{pmatrix} \Psi \end{pmatrix} \]

with

- \( U = [a_1 b_1 \cdots a_n b_n] \),
- \( \Sigma = \begin{bmatrix} \Sigma_0 & 0 \\ 0 & 0 \end{bmatrix} \), \( \Sigma_0 = \text{diag}([\sigma_1 \cdots \sigma_r]) \),
- \( V = \begin{bmatrix} \Theta - e \Theta^T \Theta & m^{-1/2} \Omega \\ -\Theta^T \Theta + e(m-1)\Theta^T \Theta & m^{-1/2} \end{bmatrix} \) with \( e = (m-1)^{-1}(1 - m^{-1/2}) \) and some \( \Theta \in \mathbb{R}^{(m-1) \times (m-1)} \) s.t. \( \Theta^T \Theta = \Theta \Theta^T = I \).

Hereby, \( a_\ell \pm b_\ell i \) with \( a_\ell, b_\ell \in \mathbb{R}^{2n} \) for \( \ell = 1, \ldots, n \) are the eigenvectors of \( T_d \). Since \( U \), as defined in (89), is constructed by the real and imaginary parts of the eigenvectors of the matrix \( T_d \), \( U \) is orthogonal [22]. Moreover,

\[ X := U^T T_d U = \text{diag}([C_1 \cdots C_n]), \]

with \( C_\ell = \begin{bmatrix} \gamma_\ell & -\delta_\ell \\ \delta_\ell & \gamma_\ell \end{bmatrix}, \ell = 1, \ldots, n, \)

where \( \gamma_\ell \pm \delta_\ell i \) are the eigenvalues of \( T_d \) with \( 2a_2 - (a_1 + a_2)^2 \gamma_\ell \in \mathbb{R} \geq 0 \) and \( \delta_\ell \in \mathbb{R} \geq 0 \). Note that \( \gamma_\ell = 0 \) and \( \delta_\ell = 0 \) for \( \ell > \text{rk}(T_d) \).

The orthogonality of \( V \), given in (91), is shown by direct evaluation:

\[ V^T V = \begin{bmatrix} \hat{V}_{11} & 0 \\ 0 & 1 \end{bmatrix} \]

with

\[ \hat{V}_{11} = I + (1 - 2e + e^2(m-1))\Theta^T \begin{pmatrix} \Omega \end{pmatrix} \Theta, \]

\[ VV^T = \begin{bmatrix} \hat{V}_{11} & \hat{V}_{12} \\ \hat{V}_{12}^T & \hat{V}_{22} \end{bmatrix} \]

with

\[ \hat{V}_{11} = I + (e^2(m-1) + m^{-1} - 2e)\Theta^T \Theta, \]

\[ \hat{V}_{12} = -e^2(m-1) - 2e(m-1) - m^{-1} + 1 \Theta^T \Theta, \]

\[ \hat{V}_{22} = e^2(m-1)^3 - 2e(m-1)^2 + m^{-1} + m^{-1} \]

where we used the fact that \( \Theta \) in (91) is orthogonal. By plugging \( e = (m-1)^{-1}(1 - m^{-1/2}) \) into (93) and (94), the orthogonality of \( V \), i.e., \( VV^T = V^T V = I \) is recovered. Now plugging (88) into (22) associated with (92) reveals

\[ \begin{bmatrix} \Sigma_0 & 0 \\ 0 & 0 \end{bmatrix} V^T P V \begin{bmatrix} \Sigma_0 & 0 \\ 0 & 0 \end{bmatrix} = X, \]

where

\[ Q := V^T P V = \begin{bmatrix} \hat{Q} & * \\ * & * \end{bmatrix} \quad \text{with} \quad \hat{Q} = \Theta^T \hat{P} \Theta \quad \text{and} \quad \hat{P} = (P - e(1 \hat{I} + P \hat{I}^T) + e^2 \hat{I} \hat{P} \hat{I}^T )_{1:m-1} \]

with \( \hat{P} \in \mathbb{R}^{(m-1) \times (m-1)} \), which can be written as

\[ \hat{P} = (a_2 - \frac{1}{2}(a_1 + a_2)^2) \]

\[ \times \left[ \begin{array}{ccc} 0 & d_1 & d_2 & \cdots & d_{m-2} \\ -d_1 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots \\ d_{m-2} & \cdots & -d_2 & -d_1 & 0 \end{array} \right] \]

with \( d_i = 2ei - 1 \) for \( i = 1, \ldots, m-2 \) and \( e \) defined in (91), where \( \hat{P} \hat{P}^T - \hat{P}^T \hat{P} = 0 \), hence \( \hat{P} \) normal. More precise, \( \hat{P} \) has complex conjugated eigenvalues \( \mu_\ell \pm \omega_\ell i \) with \( \ell = 1, \ldots, [(m-1)/2] \) where \( \mu_\ell = \mu = a_2 - 1/2(a_1 + a_2)^2 \) and the skew-symmetric part is a Toeplitz matrix (third line of (98)).

Eventually, (95) impose the conditions

\[ X_{1:r} = \Sigma_1 \hat{Q}_{1:r} \Sigma_0, \]

\[ X_{r+1:n} = 0. \]

with \( r = \text{rk}(T_d) \). Then, (100) holds, since there exist \( n - r - 1 \) eigenvalues identical to zero and \( U \) can be ordered, accordingly. Additionally, let \( \Theta \) in (91) be of the form such that

\[ \hat{Q}_{1:r} = \text{diag}([D_1 \cdots D_{[r/2]}]) \]

with \( D_\ell = \begin{bmatrix} \mu & -\omega_\ell \\ \omega_\ell & \mu \end{bmatrix}, \ell = 1, \ldots, [r/2] \)

holds, where the imaginary part of the eigenvalues of the principal submatrix \( \hat{Q}_{1:r} \) of \( \hat{Q} \) in (96) is denoted by \( \pm \omega_\ell i \) for \( k = 1, \ldots, [r/2] \).

Then (99) implies for \( k = 1, \ldots, [r/2] \)

\[ \mu\omega_{2k-1} = \mu\omega_{2k} = \gamma_k \quad \text{and} \]

\[ \sigma_{2k-1} \sigma_{2k} \omega_k = \delta_k. \]

In the case of \( 2a_2 - (a_1 + a_2)^2 = 0 \), \( T_d \) and \( \hat{P} \) are skew-symmetric due to the assumption in Theorem 3 and (98), respectively. Hence, \( \gamma_\ell = 0 \) for \( \ell = 1, \ldots, n \), and \( \mu = 0 \), which implies that (102) is satisfied. Equation (103) is satisfied for \( k = 1, \ldots, [r/2] \) with

\[ \sigma_{2k} = \delta_k \omega_k^{-1} \sigma_{2k-1} \quad \text{and} \quad \sigma_{2k-1} \in \mathbb{R}^{>0} \]

where \( m = r + 1 \) and therefore \( \omega_k = \omega_k \). Then \( \Theta \) is constructed as orthogonal transformation similar to \( U \).

In the case \( 2a_2 - (a_1 + a_2)^2 \neq 0 \), (102) and (103) together yield

\[ \sigma_{2k-1}^2 = \sigma_{2k}^2 = \frac{\delta_k}{\omega_k} = \frac{\gamma_k}{\mu}. \]
for $k = 1, \ldots, \lceil r/2 \rceil$, hence
\[ \omega_k = \frac{\delta_k}{\gamma_k} \mu \]  
(106)

has to be satisfied. Note that $\delta_k$, $\gamma_k$, and $\mu$ are specified by $T_d$ and $a_1, a_2$ and $\mu/\gamma_k \geq 0$ due to the positive definiteness condition in Theorem 3. Applying Lemma 5 to $P$ in (96) implies that there exists a $\Theta$ such that (101) and the interlacing property
\[ \omega_k \geq \omega_k' \geq \omega_k'\left[(m-1)/2\right]-\lceil r/2 \rceil + k, \quad k = 1, \ldots, \lceil r/2 \rceil \]  
(107)

holds, where $\hat{\omega}_k$ can be chosen in the given intervals. Note that Lemma 5 can be applied to the normal matrix $P$, due to the decomposition of a scaled unit and skew-symmetric matrix. W.l.o.g., $\delta_k/\gamma_k$ and $\omega_k$ are in decreasing order. Then by applying Conjecture 1 (cf. Remark 3) to $\tilde{P}$ in (97) successively, there exists a $m \geq r + 1$ such that (107) hold with (106) for all $k = 1, \ldots, \lceil r/2 \rceil$.

\section*{B.4. Proof Theorem 4}

Let $2a_2 - (a_1 + a_2)^2 = 0$ and $T(W) = T_d$ is partitioned as in (16). Since $T_d$ has to be skew-symmetric (see also Theorem 3), the eigenvalues of $T_d$ are purely imaginary. Then condition (14) with $T_{12} = -T_{21}^T = -R \in \mathbb{R}^{n \times \bar{n}}$, where $R$ is arbitrary, reads
\[
\begin{align*}
-I &= g'(z)f(z)R^T - f'(z)g(z)R \\
&+ f'(z)f(z)T_{11} + g'(z)g(z)T_{22}.
\end{align*}
\]  
(108)

Since, $T_{11} = -T_{11}^T$, $T_{22} = -T_{22}^T$, w.l.o.g. we can express $R$ as $R = I + \bar{R}$, where diag$(R) = 0$. Hence, it has to hold
\[ g'(z)f(z) - f'(z)g(z) = -1, \]  
(109)

which is satisfied by the generating functions [31, Theorem 1]
\[ g(z) = -f(z) \int \frac{1}{f^2(z)} dz. \]  
(110)

Assume that generating functions $f$ and $g$ as in (110) satisfy (109), then condition (108) translates into
\[
\begin{align*}
f'(z)f(z)T_{11} + g'(z)g(z)T_{22} \\
= f'(z)g(z) + g'(z)f(z)\tilde{R},
\end{align*}
\]  
(111)

implying that $\tilde{R} = -\tilde{R}^T$ holds. Next we consider three cases:

**Case 1:** $\bar{R} = 0$. Hence,
\[ f'(z)f(z)T_{11} + g'(z)g(z)T_{22} = 0. \]  
(112)

Clearly, (112) is satisfied by $T_{11} = T_{22} = 0$ with $f$ arbitrary while satisfying $g$ in (110), i.e., (30) results.

For the sub-case $a^{-1}T_{11} = b^{-1}T_{22} =$: Q arbitrary skew-symmetric with $a, b \in \mathbb{R}_{>0}$, and $f$ and $g$ have to satisfy $af'(z)f(z) + bg'(z)g(z) = 0$, i.e., w.l.o.g. $af^2(z) + bg^2(z) = 1$. Accordingly, with (110) and $y'(z) = f^{-2}(z)$ it yields
\[ y'(z) = a + by^2(z). \]  
(113)

The unique solution of (113) with $\phi \in \mathbb{R}$ is
\[ y(z) = \sqrt{\frac{a}{b}} \tan \left( \sqrt{ab}z + \phi \right) \]  
(114)

and therefore with the definition of $y(z)$ and (110) one reveals (31).

Repeating the above calculations for $a^{-1}T_{11} = -b^{-1}T_{22} =$: Q arbitrary skew-symmetric yields
\[ y(z) = \sqrt{\frac{a}{b}} \tanh \left( \sqrt{ab}z + \phi \right) \]  
(115)

and therefore with the definition of $y(z)$ and (110) one reveals (32).

The remaining sub-case $T_{11} \neq \pm aT_{22}$, implies that
\[ f'(z)f(z)T_{11} = 0 \]  
(116)

since $f'(z)f(z)T_{11} + g'(z)g(z)T_{22} = 0$ must hold. If $f'(z)f(z) = 0$ and $T_{11} = Q$ arbitrary skew-symmetric, i.e.,
\[ f^2(z) = a \]  
with $a \in \mathbb{R}_{>0}$, it implies that $f(z) = \sqrt{a}$. Hence, with (110), $g'(z)g(z) \neq 0$ for all $z \in \mathbb{R}$ yields $T_{22} = 0$, i.e. (33) results.

The same argumentation holds for $g'(z)g(z) = 0$ with arbitrary skew-symmetric $T_{22}$ such that (34) is recovered.

The circumstance that $T_{11} \neq T_{22}$ with $T_{11} \neq 0$ and $T_{22} \neq 0$ is not valid due to (110) and (116). Specifically, $f'(z)f(z) = 0$ and $g'(z)g(z) = 0$ has to hold; obviously, based on the above cases, $f(z) = \sqrt{a}$ and $g(z) = \sqrt{a}$ are in conflict with (109).

**Case 2:** $f'(z)g(z) + g'(z)f(z) = 0$ for all $z \in \mathbb{R}$. Hence,
\[ f'(z)f(z)T_{11} + g'(z)g(z)T_{22} = 0 \]  
(117)

\[ f'(z)g(z) + g'(z)f(z) = 0 \]  
(118)

has to be satisfied. Clearly, (117) is satisfied by $T_{11} = T_{22} = 0$, where (118) implies $-af'(z)g(z) = 1$ with $a \in \mathbb{R}_{>0}$. Accordingly, with (110) and $y'(z) = f^{-2}(z)$ it yields
\[ y'(z) = ay(z). \]  
(119)

The unique solution of (119) with $c \in \mathbb{R}$ is
\[ y(z) = e^{\alpha z} + c \]  
(120)
and therefore with the definition of \( y(z) \) and (110) one gets (35).

The sub-cases where \( a^{-1}T_{11} = b^{-1}T_{22} = \): \( Q \) arbitrary skew-symmetric or \( T_{11} \neq \pm aT_{22} \) as discussed for Case 1 are not valid. With the same approach as above, i.e., \( y'(z) = f^{-2} \) it yields to \( y'(z) = 0 \) and therefore no solution for \( f(z) \) (and \( g(z) \)) can be found or (117) and (118) are not satisfied as discussed in the last paragraph of Case 1, respectively.

**Case 3:** \( \tilde{R} = -\tilde{R}^\top \neq 0 \). Hence,

\[
f'(z)f(z)T_{11} + g'(z)g(z)T_{22} = (f'(z)g(z) + g'(z)f(z))\tilde{R}.
\]

(121)

Clearly, \( T_{11} = T_{22} = 0 \) is not valid, since \( (f'(z)g(z) + g'(z)f(z))\tilde{R} \neq 0 \) in this last case.

For the sub-case \( a^{-1}T_{11} = b^{-1}T_{22} = : \) \( Q = -Q^\top \neq 0 \) with \( a, b \in \mathbb{R}_{>0} \), it has to hold that \( af'(z)f(z) + bg'(z)g(z) = c(f'(z)g(z) + g'(z)f(z)) \) and \( \tilde{R} = cQ \) with \( c \in \mathbb{R} \setminus \{0\} \), i.e., w.l.o.g. \( \alpha = \sqrt{d^2 \tilde{R}} \) and \( \tilde{R} = cQ \) yields

\[
y'(z) = \frac{a}{2} + cy(z) + \frac{b}{2} \tilde{g}(z).
\]

(122)

The unique solution of (122) with \( \phi \in \mathbb{R} \) is

\[
y(z) = \frac{\sqrt{ab - c^2}}{b} \tan \left( \sqrt{ab - c^2}z + \phi \right)
\]

(123)

and therefore with the definition of \( y(z) \) and (110) one reveals (36).

The remaining sub-case \( T_{11} \neq aT_{22} \), implies that

\[
f'(z)f(z)T_{11} - (f'(z)g(z) + g'(z)f(z))\tilde{R} = 0 \quad \text{and}
\]

\[
g'(z)g(z)T_{22} = 0, \quad \text{or}
\]

\[
g'(z)g(z)T_{22} - (f'(z)g(z) + g'(z)f(z))\tilde{R} = 0 \quad \text{and}
\]

\[
f'(z)f(z)T_{11} = 0,
\]

(124)

(125)

since (121) must hold. However, we show in the sequel that (124) and (125) lead to no new solution or is not valid, respectively.

For (124), \( a^{-1}T_{11} = c^{-1}\tilde{R} = : \) \( Q = -Q^\top \neq 0 \) with \( a \in \mathbb{R}_{>0} \) and \( c \in \mathbb{R} \{0\} \), it has to hold that \( af'(z)f(z) = c(f'(z)g(z) + g'(z)f(z)) \) i.e., w.l.o.g.

\[
\frac{a}{2} f'^2(z) - cf(z)g(z) = 1.
\]

(126)

Accordingly, with (110) and \( y'(z) = f^{-2}(z) \) it yields

\[
y'(z) = \frac{a}{2} + cy(z).
\]

(127)

The unique solution of (125) with \( d \in \mathbb{R} \) is

\[
y(z) = de^cz - \frac{a}{2c}
\]

(128)

and therefore with the definition of \( y(z) \) and (110) one gets \( f(z) = (cd)^{-1/2}\exp(-cz) \) and \( g(z) = -(d/c)^{-1/2}\exp(cz) \) such that \( T_{22} = 0 \). However, \( f, g \) satisfying (126) for all \( z \in \mathbb{R} \) only for \( a = 0 \), hence \( T_{11} = 0 \), i.e. the same result as (35).

For (125), \( b^{-1}T_{11} = c^{-1}\tilde{R} = : \) \( Q = -Q^\top \neq 0 \) with \( a \in \mathbb{R}_{>0} \) and \( c \in \mathbb{R} \{0\} \), it has to hold that \( bg'(z)g(z) = c(f'(z)g(z) + g'(z)f(z)) \), i.e., w.l.o.g.

\[
\frac{b}{2}g^2(z) - cf(z)g(z) = 1.
\]

(129)

Following the procedure above yields \( f(z) = (2^{-1/2}c^{-1}(b\exp(cz) - d/2) - \exp(-cz - d/2)) \) and \( g(z) = 2^{1/2}b^{-1}\exp(-cz - d/2) \) with \( d \in \mathbb{R} \). However, (129) is only satisfied for \( d = -cz - \ln(b) \) which leads to \( f(z) = 0 \) and therefore no valid solution.

Notice that every feasible structure of the skew-symmetric matrix \( T_d \) is discussed above case by case, and the differential equations arising in the analysis are solved uniquely. Hence, we believe that the list of triples \( (T_d, f, g) \) in Theorem 4 for \( 2a_2 - (a_1 + a_2)^2 = 0 \) and \( T_d \) skew-symmetric is essentially exhaustive, save for some scaled version of the presented cases.

\[\square\]

**B.5. Proof Theorem 5**

Let \( T_d \) be normal and \( (2a_2 - (a_1 + a_2)^2)(T_d + T_d^\top) \) be positive definite and let \( T(W) = T_d = \) be partitioned as in (16). Then equation (14) reads

\[
-I = f'(z)f(z)T_{11} + f'(z)g(z)T_{12} + g'(z)f(z)T_{21} + g'(z)g(z)T_{22}.
\]

(130)

Choosing \( T_d (T(W) = T_d) \) as in (37), it holds that \( (2a_2 - (a_1 + a_2)^2)(T_d + T_d^\top) \) is positive definite, yielding

\[
-I = a \left( f'(z)f(z) + g'(z)g(z) \right) + g'(z)f(z) - f'(z)g(z).
\]

(131)

This equation has been considered in [16]. We refer to the proof of [16, Theorem 1] for the derivation of \( f \) and \( g \) as specified in (37).

Case (38) is analogous to (31). First, note that \( (2a_2 - (a_1 + a_2))(T_d + T_d^\top) \) is positive definite and normal with the given \( T_d \) in (38) and \( (2a_2 - (a_1 + a_2))(Q + Q^\top) \) is positive definite and normal, since

\[
T_d T_d^\top - T_d^\top T_d = \begin{bmatrix} QQ^\top - Q^\top Q & 0 \\ 0 & QQ^\top - Q^\top Q \end{bmatrix}
\]

(132)

and

\[
T_d + T_d^\top = \begin{bmatrix} Q + Q^\top & 0 \\ 0 & Q + Q^\top \end{bmatrix},
\]

(133)
such that the real part of the eigenvalues of $Q$ is identical to that of $T_d$ and therefore the definiteness property is conserved. Hence, the derivation of the generating functions $f$ and $g$ in this case goes along the lines of arguments as used in the proof of Theorem 4 in Appendix B.4, specifically for the case (31), i.e., (113) and (114).

The structure of normal matrices $T_d$ brings more degrees of freedom compared to $T_d$ skew-symmetric as in Theorem 4 and thus the two cases listed in Theorem 5 are not exhaustive.

C. CONSTRUCTION OF EXPLORATION SEQUENCE MATRIX

In this section we summarize the main steps to construct an exploration sequence matrix $W$ based on the constructive proof of Theorem 3 in Appendix B.3. A MATLAB toolbox of the described construction procedure in the sequel can be found in the ancillary file folder on Arxiv.

C.1. Step-by-step Construction of $W$

The exploration sequence matrix $W \in \mathbb{R}^{2n \times m}$ with dimension of the optimization variable $n$ and exploration sequence length $m$ is constructed by a singular-value decomposition

$$W = USV^T$$

with $U \in \mathbb{R}^{2n \times 2n}$, $\Sigma \in \mathbb{R}^{2n \times m}$, and $V \in \mathbb{R}^{m \times m}$, where $m$ has to be determined. In the following $U, \Sigma, V$ as stated in (89) to (91) are constructed.

**Step 1**: Choose design parameters. Select the map parameters $a_1, a_2 \in \mathbb{R}$ with $a_1 + a_2 \neq 0$, and $T_d \in \mathbb{R}^{2n \times 2n}$ according to Theorem 4 and Theorem 5 with $r = \text{rk}(T_d)$.

**Step 2**: Calculate eigenvalues and eigenvectors of $T_d$. Calculate eigenvalues of $T_d$ with $\gamma_\ell = \delta_\ell i$ where $\gamma_\ell \in \mathbb{R}$, $\delta_\ell \in \mathbb{R}_{\geq 0}$ and eigenvectors of $T_d$ with $a_\ell \pm i b_\ell$ where $a_\ell, b_\ell \in \mathbb{R}^{2n}$ for $\ell = 1, \ldots, n$. The eigenvalues are sorted according to $\delta_1 \geq \delta_2 \geq \cdots \geq \delta_n \geq 0$. Note that $\gamma_\ell = 0$ if $T_d$ skew-symmetric and $\gamma_p = 0, \delta_p = 0$ for $p = \lceil r/2 \rceil + 1, \ldots, n$.

**Step 3**: Calculate $U$. Construct as specified in (89).

**Step 4**: Design $\Sigma$. The principal submatrix of $\Sigma$ is constructed as $\Sigma_0 = \text{diag}(\sigma_1, \ldots, \sigma_r) \in \mathbb{R}^{r \times r}$ with the singular values $\sigma_k$ of $W$. This step has various degrees of freedom to influence the sequence length $m$; distinguished in the following:

I. $T_d$ skew-symmetric
   i) $m = r + 1$
   ii) $m \geq r + 1$ ($m$ determined in Step 5)

II. $T_d$ as in (39)
   i) $m = 2n + 1$
   ii) $m \geq 2n + 1$ ($m$ determined in Step 5)

III. $T_d$ normal and $(2\alpha^2 - (a_1 + a_2)^2)(T_d + T_d^\top)$ positive definite ($m$ determined in Step 5)

For I.i) and II.i), calculate the eigenvalues of $\tilde{P}(m)$ in (27) with $\mu \pm \omega_k i$ for $k = 1, \ldots, [m/2]$, $\mu \in \mathbb{R}, \omega_k \in \mathbb{R}_{\geq 0}$ and $\alpha_1 \geq \omega_2 \geq \cdots \geq \omega_{[m/2]} \geq 0$. The choices of $\sigma_{2r-1}, \sigma_{2r}$ for $k = 1, \ldots, \lceil r/2 \rceil$ for each case above is presented in the following:

I.i) $\sigma_{2r} = \delta_r \omega_r^{-1} \sigma_{2r-1}^{-1}$ and $\sigma_{2r-1} \in \mathbb{R}_+$
I.ii) $\sigma_{2r} \in \mathbb{R}_+$

II.i) $\sigma_{2r-1} = \sigma_{2r} = \omega_r^{-1/2}$
II.ii) $\sigma_{2r-1} = \sigma_{2r} \in \mathbb{R}_+$

III. $\sigma_{2r-1} = \sigma_{2r} = \gamma_r^{1/2}(\alpha_2 - (a_1 + a_2)^2)^{-1/2}$

Note that $\Sigma$ depends on $m$, i.e., for I.i), II.i), and III. $m$ has to be determined (see Step 5) first. Then, and for cases I.i) and II.i) $\Sigma = \text{diag}([\Sigma_0 m_{0\rightarrow r}])$ can be constructed.

**Step 5**: Determine sequence length $m$. If in Step 4, $\Sigma$ was constructed based on I.i) or II.i), $m = r + 1$ or $m = 2n + 1$, respectively (proceed directly with Step 6). Otherwise, calculate

$$\hat{\sigma}_{\pi(\ell)} = \delta_\ell (\sigma_{2r-1} \sigma_{2r})^{-1}$$

with $\sigma_{2r-1}, \sigma_{2r}$ as designed in Step 4 for $\ell = 1, \ldots, \lceil r/2 \rceil$ and permutation $\pi : \{1, \ldots, \lceil r/2 \rceil \} \rightarrow \{1, \ldots, \lceil r/2 \rceil \}$ such that $\hat{\sigma}_1 \geq \hat{\sigma}_2 \geq \cdots \hat{\sigma}_{\lceil r/2 \rceil} \geq 0$. Construct the permutation matrix $\hat{R}(\pi) \in \mathbb{R}^{\lceil r/2 \rceil \times \lceil r/2 \rceil}$ as

$$\hat{R}(\pi) = [\hat{e}_{2\pi(1)} \hat{e}_{2\pi(2)} \cdots \hat{e}_{2\pi(\ell)}]$$

Then, set $\hat{m} = r + 1$ and apply the following steps:

(a) Calculate $\hat{P}(\hat{m})$ as defined in (27).

(b) Calculate eigenvalues of $\hat{P}(\hat{m})$ with $\mu \pm \omega_k i$ where $\mu \in \mathbb{R}, \omega_k \in \mathbb{R}_{\geq 0}$ for $k = 1, \ldots, [\hat{m}/2]$ and $\alpha_1 \geq \omega_2 \geq \cdots \geq \omega_{[\hat{m}/2]}$.

(c) Check if the interlacing property

$$\omega_k \geq \hat{\omega}_k \geq \omega_{[\hat{m}/2] - \lceil r/2 \rceil + k}$$

for every $k = 1, \ldots, \lceil r/2 \rceil$ is satisfied with $\hat{\omega}_k$ calculated in (135).

(d) If (c) is true, $m = \hat{m}$. Otherwise, $\hat{m} \leftarrow \hat{m} + 1$ and goto (a).
Step 7: Calculate $V$. Construct $V$ as specified in (91). Therein, the required orthogonal matrix $\Theta \in \mathbb{R}^{(m-1) \times (m-1)}$ is calculated as

$$\Theta = \begin{bmatrix} \hat{R}(\pi) & 0 \\ 0 & I \end{bmatrix}$$  \hspace{1cm} (138)$$

with $\hat{\Theta} \in \mathbb{R}^{(m-1) \times (m-1)}$ based on the construction procedure for principle submatrices below (cf. Appendix C.2), where in there

$$C = \bar{P}(m) - I(a_2 - (a_1 + a_2)^2)$$  \hspace{1cm} (139)$$

with $\bar{P}(m)$ in (27) and $[\hat{\omega}_k]_{k=1,\ldots,[r/2]}$ calculated in (135) has to be applied.

Step 8: Determine $W$. Finally, construct $W$ according to (134).

C.2. Construction Procedure of Principal Submatrix

In this section we present a procedure to construct an orthogonal matrix $\Theta \in \mathbb{R}^{p \times p}$, such that for a given skew-symmetric matrix $C \in \mathbb{R}^{p \times p}$ with eigenvalues $\pm \eta_i$, $\eta_i \in \mathbb{R}_{\geq 0}$ for $\ell = 1, \ldots, [p/2]$, and for given values $[\hat{\omega}_k]_{k=1,\ldots,q}$ ($p \geq 2q$), which are satisfying the interlacing inequalities

$$\eta_k \geq \hat{\omega}_k \geq \eta_{[p/2]-q+k}, \hspace{0.5cm} k = 1, \ldots, q;$$  \hspace{1cm} (140)$$

it holds that

$$\Theta^\top C \Theta = \begin{bmatrix} Q & * \\ * & * \end{bmatrix}$$

$$Q = \text{diag}([Q_1 \ Q_2 \cdots Q_{\ell}]), \hspace{1cm} Q_k = \begin{bmatrix} 0 & -\hat{\omega}_k \\ \hat{\omega}_k & 0 \end{bmatrix}.$$  \hspace{1cm} (141)$$

Thus, $Q$ is the principal submatrix of $C$, where $q$ and $[\hat{\omega}_k]_{k=1,\ldots,q}$ can be chosen w.r.t. (140). The main procedure to construct $\Theta$ is given in Algorithm 2 (p. 23) as an iterative algorithm. In each iteration $j = 1, \ldots, [p/2] - q$, a $\Theta_j \in \mathbb{R}^{p \times p}$ is constructed, described in the sub-routine Algorithm 4 (p. 24), such that

$$(\Theta_1 \Theta_2 \cdots \Theta_j)^\top C \Theta_1 \Theta_2 \cdots \Theta_j = \begin{bmatrix} D_j & * \\ * & * \end{bmatrix}$$  \hspace{1cm} (141)$$

is satisfied, where $D_j \in \mathbb{R}^{[2((p-j)/2)] \times 2((p-j)/2)}$ is a block diagonal skew-symmetric matrix with eigenvalues $\pm \nu_i$, $\nu_i \in \mathbb{R}_{\geq 0}$, which are satisfying the interlacing inequalities

$$\eta_k \geq \nu_k \geq \eta_{[p/2]-j+k}, \hspace{1cm} k = 1, \ldots, [p/2] - j;$$  \hspace{1cm} (142)$$

for $k = 1, \ldots, [p/2] - j$, where $D_j$ is determined in the sub-routine Algorithm 3 (p. 24).

In particular, the sub-routine given in Algorithm 4 (p. 24), constructs a $\hat{\Theta} \in \mathbb{R}^{s \times s}$ such that for two given skew-symmetric matrices $D_1 \in \mathbb{R}^{s \times s}$ and $D_2 \in \mathbb{R}^{s \times s}$ in block diagonal form, where $s = 2\lceil (r - 1)/2 \rceil$ (hence $s$ always even), it holds that

$$\hat{\Theta} D_1 \hat{\Theta}^\top = \begin{bmatrix} D_2 & * \\ * & * \end{bmatrix},$$  \hspace{1cm} (143)$$

and the eigenvalues $\pm \delta_i, \delta_i \in \mathbb{R}_{\geq 0}$ for $k = 1, \ldots, [r/2]$ of $D_1$ and the eigenvalues $\pm \xi_i, \xi_i \in \mathbb{R}_{\geq 0}$ for $k = 1, \ldots, s/2$ of $D_2$ satisfy the interlacing inequality

$$\delta_1 \geq \xi_1 \geq \delta_2 \geq \xi_2 \geq \cdots \geq \xi_{s/2} \geq \delta_{[r/2]} \geq 0.$$  \hspace{1cm} (144)$$

The sub-routine given in Algorithm 3 (p. 24) constructs a block diagonal skew-symmetric matrix $\hat{D} \in \mathbb{R}^{(\lceil t/2 \rceil - 1) \times 2(\lceil t/2 \rceil - 1)}$ with eigenvalues $\pm \gamma_i, \gamma_i \in \mathbb{R}_{\geq 0}$, $i = 1, \ldots, [t/2] - 1$, such that for a given skew-symmetric matrix $D \in \mathbb{R}^{t \times t}$ with eigenvalues $\pm \gamma_i, \gamma_i \in \mathbb{R}_{\geq 0}$, $i = 1, \ldots, [t/2]$, the interlacing inequality

$$\gamma_1 \geq \gamma_{[t/2]-1} \geq \gamma_{[t/2]} \geq 0.$$  \hspace{1cm} (145)$$

is satisfied. Additionally, the interlacing inequalities

$$\gamma_k \geq \hat{\omega}_k \geq \gamma_{[t/2]-q+k}, \hspace{0.5cm} k = 1, \ldots, q$$  \hspace{1cm} (146)$$

hold.

Summarizing, Algorithm 3 (p. 24) computes a principle submatrix of a dimension that is two (or one in the first iteration) less than in the previous iteration in Algorithm 2 (p. 23), while the interlacing property (140) is preserved by (146). Then, Algorithm 4 (p. 24) constructs a $\Theta_j$ (iteration $j = 1, \ldots, [p/2] - q$) based on $D_j$, calculated in Algorithm 3 (p. 24), such that the computed principle submatrix is obtained by an orthogonal transformation as written in (141). This is repeated until the principal submatrix is the block diagonal matrix with eigenvalues $[\hat{\omega}_k]_{k=1,\ldots,q}$.

Note that the function eigVal$(\cdot)$ in Algorithm 3 and Algorithm 4 (p. 24f) computes the eigenvalue of a matrix in decreasing order w.r.t. to the imaginary part (in Algorithm 4 (p. 24) only skew-symmetric matrices are present).

Remark 10. Note that Algorithm 4 (p. 24) is the construction procedure of the sufficient interlacing eigenvalue statement in Lemma 4, whereas Algorithm 2 (p. 23) is the construction procedure of Lemma 5.

To verify this constructive approach we follow the lines of the proof of [32, Lemma B.3.], in which symmetric matrices that satisfy the interlacing property (72) are considered. Because of minor changes in the proof, we present only the case for $p$ odd; thus, we construct $D_1 \in \mathbb{R}^{p \times p}$.
Algorithm 2. Calculate $\Theta$

1: Given: $C \in \mathbb{R}^{p \times p}$, $[\hat{w}_k]_{k=1, \ldots, q}$
2: if $p = 2q$ then
3: $D_0 = C$
4: $\Theta_1 = \{ \hat{w}_k \}_{k=1, \ldots, q}$
5: else ($p > 2q$)
6: $D_j = \text{calcPSMatrix}(D_{j-1}, [\hat{w}_k]_{k=1, \ldots, q})$
7: $\Theta_j = \text{calcThetaSub}(D_{j-1}, D_j)$
8: $\Theta = \Theta_j \Theta_2 \cdots \Theta_{|p/2| - q}$

Algorithm 3. Sub-routine: calculate principal submatrix

1: function $D = \text{calcPSMatrix}(D, [\hat{w}_k]_{k=1, \ldots, q})$
2: $[\pm \gamma_k]_{k=1, \ldots, [t/2]} = \text{eigVal}(D)$
3: for $j = 1, \ldots, [t/2] - 2$ do
4: $\rho = \{ \hat{w}_k \}_{k=1, \ldots, q}$
5: $\nu_j = \max(\{ \gamma_j, 1, \ldots, [t/2] \} - \rho$
6: end for
7: $v_{[t/2]-1} = \max(\{ \hat{w}_k \}_{k=1, \ldots, q})$
8: for $j = 1, \ldots, [t/2] - 1$ do
9: $N_j = \begin{bmatrix} 0 & -v_j \\ v_j & 0 \end{bmatrix}$
10: end for
11: $D = \text{diag}([N_1, N_2, \ldots, N_{[t/2]-1}])$
12: end function

with $D_2 \in \mathbb{R}^{(p-1) \times (p-1)}$ and $z \in \mathbb{R}^{p-1}$ as specified in Algorithm 4 (p. 24). Then

$$g(\lambda) := \det(\lambda I - \bar{D}_1) = \prod_{i=1}^{[p/2]} (\lambda^2 + \delta_i^2), \quad (147)$$

$$f(\lambda) := \det(\lambda I - D_2) = \prod_{i=1}^{[p/2]} (\lambda^2 + \nu_i^2)$$

$$= g(\lambda) (\lambda + z^T (\lambda I - \bar{D}_1)^{-1} z)$$

$$= \lambda g(\lambda) \left( 1 + \sum_{i=1}^{[p/2]} \frac{z_{2i-1}^2 + z_{2i}^2}{\lambda^2 + \delta_i^2} \right) \quad (148)$$

hold. Let for $j = 1, \ldots, [p/2]$

$$z_{2j-1}^2 = z_{2j}^2 = - \left( \prod_{i=1}^{[p/2]} (\delta_i^2 - \nu_i^2) \right) \left( 2 \prod_{i=1}^{[p/2]-1} (\delta_i^2 - \delta_i^2) \right)^{-1} \quad (149)$$

then with $\lambda = \pm \nu_i$, $\ell = 1, \ldots, [p/2]$

$$\sum_{i=1}^{[p/2]} \frac{z_{2i-1}^2 + z_{2i}^2}{\lambda^2 + \delta_i^2} = - \sum_{k=1}^{[p/2]} \frac{\prod_{i \neq k} (\delta_i^2 - \delta_k^2)}{\prod_{i \neq k} (\delta_i^2 - \delta_k^2)} = -1. \quad (150)$$

Thus, $f(\pm \nu_i) = 0$, $\ell = 1, \ldots, [p/2]$ and therefore $\pm \nu_i$ are the eigenvalues of $\bar{D}_1$, while the eigenvalues of the principal submatrix $D_2$ are $\pm \delta_i$, $\ell = 1, \ldots, [p/2]$. 
Algorithm 4. Sub-routine: calculate $\hat{\Theta}$

1: function $\hat{\Theta} = \text{calcThetaSub}(D_1, D_2)$
2:    $[\pm \delta_k]_{k=1,\ldots,[r/2]} = \text{eigVal}(D_1)$
3:    $[\pm \xi_k]_{k=1,\ldots,s/2} = \text{eigVal}(D_2)$
4:    for $j = 1,\ldots,[r/2] - 1$ do
5:        $x_j = \left( \prod_{i=1}^{[r/2]} (\xi_j^2 - \delta_i^2) \right)$, $y_j = \left( 2 \prod_{i\neq j}^{[r/2]-1} (\xi_j^2 - \zeta_i^2) \right)$
6:    end for
7:    if $r$ even then
8:        for $j = 1,\ldots,[r/2] - 1$ do
9:            if $y_j = 0$ then
10:                $z_{2j-1} = 0$
11:                $z_{2j} = 0$
12:            else
13:                $z_{2j-1} = (-x_jy_j^{-1}r_j^{-1})^{1/2}$
14:                $z_{2j} = z_{2j-1}$
15:            end if
16:        end for
17:        $z_{r-1} = \left( \prod_{i=1}^{[r/2]} (\delta_i) \right) \left( \prod_{i=1}^{[r/2]-1} (\xi_i^{-1}) \right)$
18:        $z = [z_1 z_2 \cdots z_{r-2}]^T$
19:        $\hat{D}_1 = \begin{bmatrix} D_2 & 0 & z \\ 0 & 0 & z_{r-1} \end{bmatrix}$
20:        $[a_{\ell} \pm b_{\ell}]_{\ell=1,\ldots,[r/2]} = \text{eigVec}(D_1)$
21:        $[c_{\ell} \pm d_{\ell}]_{\ell=1,\ldots,[r/2]} = \text{eigVec}(D_1)$
22:        $\Theta = [a_1 b_1 d_1 \cdots a_{[r/2]} b_{[r/2]}]$  
23:        $\hat{\Theta} = [c_1 d_1 c_2 d_2 \cdots c_{[r/2]} d_{[r/2]}]$  
24:    else (r odd)
25:        for $j = 1,\ldots,[r/2]$ do
26:            if $y_j = 0$ then
27:                $z_{2j-1} = 0$
28:                $z_{2j} = 0$
29:            else
30:                $z_{2j-1} = (-x_jy_j^{-1})^{1/2}$
31:                $z_{2j} = z_{2j-1}$
32:            end if
33:        end for
34:        $z = [z_1 z_2 \cdots z_{r-1}]^T$
35:        $\hat{D}_1 = \begin{bmatrix} D_2 & z \\ -z^T & 0 \end{bmatrix}$
36:        $[a_{\ell} \pm b_{\ell}]_{\ell=1,\ldots,[r/2]} = \text{eigVec}(D_1)$
37:        $[c_{\ell} \pm d_{\ell}]_{\ell=1,\ldots,[r/2]} = \text{eigVec}(D_1)$
38:        $\Theta = [a_1 b_1 d_1 \cdots a_{[r/2]} b_{[r/2]} a_{[r/2]}]$  
39:        $\hat{\Theta} = [c_1 d_1 c_2 d_2 \cdots c_{[r/2]} d_{[r/2]} c_{[r/2]}]$  
40:    end if
41:    $\hat{\Theta} = \Theta \hat{\Theta}$
42: end function
