Abstract
We study the inverse spectral problem of reconstructing energy-dependent Sturm–Liouville equations from their Dirichlet spectra and sequences of the norming constants. For the class of problems under consideration, we give a complete description of the corresponding spectral data, suggest a reconstruction algorithm, and establish uniqueness of reconstruction. The approach is based on connection between spectral problems for energy-dependent Sturm–Liouville equations and for Dirac operators of a special form.

1. Introduction

The main aim of the paper is to study the inverse spectral problem of reconstructing Sturm–Liouville differential equations on (0, 1) with energy-dependent potentials from their Dirichlet spectra and suitably defined norming constants. The spectral problem of interest is given by the differential equation

\[-y'' + qy + 2\lambda p y = \lambda^2 y\]  \hspace{1cm} (1.1)

and the Dirichlet boundary conditions

\[y(0) = y(1) = 0.\] \hspace{1cm} (1.2)

Here, \(p\) is a real-valued function in \(L_2(0, 1)\) and \(q\) is a real-valued distribution in \(W^{-1}_2(0, 1)\); see detailed definitions in the following section.

Sturm–Liouville spectral problems with potentials depending on the spectral parameter arise in various models of quantum and classical mechanics. For instance, the evolution equations (such as the Klein–Gordon equation [26, 43]) that are used to model interactions between colliding relativistic spinless particles can be reduced to the form (1.1). Then \(\lambda^2\) is related to the energy of the system, thus explaining the term ‘energy-dependent’ in the title of the paper. Another typical example is related to vibrations of mechanical systems in viscous media, see [58].
Problems of the form (1.1) have also appeared in the physical literature in the context of scattering of waves and particles. In particular, Jaulent and Jean in [22–25] studied the inverse scattering problems for energy-dependent Schrödinger operators on the line; see also the papers [3, 27, 36, 37, 39, 40, 48, 55, 56]. An interesting approach to the spectral analysis of the Klein–Gordon equations using the Krein spaces (i.e. spaces with indefinite scalar products) was suggested by Jonas [26] and Langer, Najman and Tretter [33, 34, 43].

Nonlinear dependence of equation (1.1) on the spectral parameter \( \lambda \) suggests that (1.1) and (1.2) should be regarded as a spectral problem for a quadratic operator pencil. Although some spectral properties of such a problem can easily be derived from the general spectral theory of polynomial operator pencils [38], there have been rather few papers investigating the inverse problem of reconstructing the potentials \( p \) and \( q \) from the suitably defined spectral data. The problem with \( p \in W^1_2(0, 1) \) and \( q \in L_2(0, 1) \) and with Robin boundary conditions was discussed by Gasymov and Guseinov in their short paper [12] of 1981 containing no proofs. Such problems for (quasi-)periodic boundary conditions were considered in, e.g., [16, 17, 41, 42, 59]; however, typically only Borg-type uniqueness results were established therein. Some non-classical settings of the inverse spectral problem (e.g., those with mixed given data, Hochstadt-type problems, or inverse nodal problems) were discussed in [30–32].

The main aim of this paper is to investigate in detail the inverse spectral problem for equations (1.1) and (1.2), under minimal smoothness assumptions on real-valued potentials \( p \) and \( q \). In particular, the distributional potential \( q \) can include e.g. the Dirac delta functions or Coulomb-like singularities that are widely used in quantum mechanics to model interactions in molecules and atoms; see the monographs by Albeverio et al [4] and by Albeverio and Kurasov [7] and the extensive reference lists therein. For this wide class of problems, we shall give a complete description of the corresponding spectral data, suggest a reconstruction algorithm and establish uniqueness of reconstruction. Our approach consists in reducing the spectral problem for (1.1) and (1.2) to the one for a related Dirac operator; we then study the possibility of reconstructing a Dirac operator of a special form from its spectral data. Since various steps of our considerations are explicit, they form the basis for a reconstruction algorithm.

The paper is organized as follows. In the following section, we introduce the main objects of study and formulate the main results. In section 3, we show that the spectral problem (1.1)–(1.2) is closely related to the one for the Dirac operator of a special form. Furthermore, we discuss the possibility of transforming Dirac operators to some canonical form by means of the so-called transformation operators. Existence and uniqueness of a special Dirac operator (and thus of the corresponding operator pencil) possessing the prescribed spectral data are tackled in sections 5 and 6, respectively. Finally, section 7 summarizes the reconstruction algorithm and discusses some possible extensions.

Notations. Throughout the paper, \((\cdot, \cdot)_{L^2}\) denotes the scalar product in \(L^2(0, 1)\). Next, \(L^2_{2,R}(0, 1)\) and \(W^{-1}_2(0, 1)\) will stand for the sets of real-valued functions in \(L^2(0, 1)\) and distributions in \(W^{-1}_2(0, 1)\), respectively. We denote by \(\rho(T)\) and \(\sigma(T)\) the resolvent set and the spectrum of a linear operator or a quadratic operator pencil \(T\), and by \(\mathcal{M}_2 = \mathcal{M}_2(\mathbb{C})\) the linear space of \(2 \times 2\) matrices with complex entries endowed with the Euclidean operator norm. The superscript \(t\) designates the transposition of vectors and matrices, e.g., \((c_1, c_2)^t\) is the column vector \(c_1, c_2\).

2. Preliminaries and main results

Equation (1.1) contains terms depending both on \(\lambda\) and \(\lambda^2\) and therefore leads to a spectral problem for a quadratic operator pencil that we now introduce.
To begin with, we recall that the potential \( q \) in (1.1) is a real-valued distribution in the Sobolev space \( W^{-1}_{2}(0,1) \) and thus \( q = r' \) for some \( r \in L_{2}(0,1) \). The Sturm–Liouville operator with potential \( q \) can be defined following the regularization method due to Savchuk and Shkalikov [49, 50]. Namely for every absolutely continuous function \( y \), we denote by \( y^{[1]} := y' - ry \) its quasi-derivative and introduce the differential expression

\[
\ell(y) := -(y^{[1]}y' - ry^{[1]}) - r^{2}y
\]

acting on

\[
\text{dom } \ell = \{ y \in AC[0,1] | y^{[1]} \in AC[0,1], \; \ell(y) \in L_{2}(0,1) \}.
\]

We now define the operator \( A \) via

\[
Ay = \ell(y)
\]

on the domain

\[
\text{dom } A := \{ y \in \text{dom } \ell | y(0) = y(1) = 0 \}.
\]

A straightforward verification shows that \( \ell(y) = -y'' + qy \) in the sense of distributions and, if \( q \) is integrable, even in the usual sense. Therefore for regular \( q, A \) is the standard Sturm–Liouville operator with potential \( q \) and Dirichlet boundary conditions. It is known [49, 50] that if \( q \in W^{-1}_{2}(0,1) \) is real-valued, then the operator \( A \) is self-adjoint, bounded below and has a simple discrete spectrum. The Green function of the operator \( A \) is continuous in the square \([0,1] \times [0,1] \), so that the resolvent of \( A \) is of Hilbert–Schmidt class.

Furthermore, we denote by \( B \) the operator of multiplication by the potential \( p \in L_{2}(0,1) \). The operator \( B \) is in general unbounded; however, since \( BA^{-1} \) is of Hilbert–Schmidt class, \( B \) is \( A \)-compact [29, chapter IV]. In particular, \( \text{dom } B \supset \text{dom } A \) and \( B \) is bounded relative to \( A \) with relative \( A \)-bound 0 [10, lemma III.2.16]. Finally, \( I \) stands for the identity operator in \( L_{2}(0,1) \).

Now the spectral problem (1.1)–(1.2) can be regarded as the spectral problem for the quadratic operator pencil \( T_{p,q} \) defined as

\[
T_{p,q}(\lambda) := \lambda^{2}I - 2\lambda B - A
\]

for \( \lambda \in \mathbb{C} \) on the \( \lambda \)-independent domain \( \text{dom } T_{p,q} := \text{dom } A \). The above-mentioned properties of the operators \( A \) and \( B \) imply that, for every \( \lambda \in \mathbb{C} \), the operator \( T_{p,q}(\lambda) \) is well defined and closed on \( \text{dom } T_{p,q} \). Before continuing, we recall the following notions of the spectral theory of operator pencils, see [38].

**Definition 2.1.** The spectrum \( \sigma(T_{p,q}) \) of the operator pencil \( T_{p,q} \) is the set of all \( \lambda \in \mathbb{C} \) for which \( T_{p,q}(\lambda) \) is not boundedly invertible, i.e.

\[
\sigma(T_{p,q}) = \{ \lambda \in \mathbb{C} | 0 \in \sigma(T_{p,q}(\lambda)) \}.
\]

A number \( \lambda \in \mathbb{C} \) is called the eigenvalue of \( T_{p,q} \) if \( T_{p,q}(\lambda)y = 0 \) for some non-zero function \( y \in \text{dom } T_{p,q} \), which is then the corresponding eigenfunction. Finally,

\[
\rho(T_{p,q}) := \mathbb{C} \setminus \sigma(T_{p,q})
\]

is the resolvent set of the operator pencil \( T_{p,q} \).

It follows from the above properties of the operators \( A \) and \( B \) and the theorem on analytic operator-valued functions [14, corollary 8.4], [15, chapter I.5] that the spectrum of the pencil \( T_{p,q} \) is a discrete subset of \( \mathbb{C} \) and consists entirely of eigenvalues of finite algebraic multiplicity [38]; see details in [46] and the reasonings of [2] for a similar problem. In general, \( T_{p,q} \) can possess non-real and/or non-simple eigenvalues (i.e. of algebraic multiplicity greater than 1). The approach to the inverse spectral problem for \( T_{p,q} \) we are going to use is currently well
understood only for the case where the spectrum of $T_{p,q}$ is real and simple. This happens, e.g., when there is a $\lambda_0 \in \mathbb{R}$ such that the operator $T_{p,q}(\lambda_0)$ is negative, i.e. when $T_{p,q}$ is a strongly hyperbolic pencil [38, chapter 31]. Making the shift $\lambda \mapsto \lambda + \lambda_0$ if necessary, we may (and shall) assume that $\lambda_0 = 0$.

Therefore, our standing assumption throughout the paper is that

(A) $p \in L_{2,\mathbb{R}}(0, 1)$, $q \in W_{2,\mathbb{R}}^{-1}(0, 1)$, and the operator $A$ is positive.

As mentioned above, under this assumption the eigenvalues of $T_{p,q}$ are all real and simple [38, chapter 31], and they can be labelled in increasing order as $\lambda_n$ for $n \in \mathbb{Z}^* := \mathbb{Z} \setminus \{0\}$, so that

$$\lambda_n = \pi n + p_0 + \tilde{\lambda}_n,$$

where $p_0 := \int_0^1 p(x) \, dx$ and $(\tilde{\lambda}_n)$ is a sequence in $\ell_2(\mathbb{Z}^*)$ [46, 44]. Note that under assumption (A), the point $\lambda = 0$ is in the resolvent set of $T_{p,q}$. Also, since the operator $A$ has compact resolvent, positivity of $A$ implies its uniform positivity, i.e. there is $\varepsilon > 0$ such that $A \geq \varepsilon I$.

Furthermore, we observe that equation (1.1) can be recast using quasi-derivatives as

$$\ell(y) + 2\lambda py = \lambda^2 y$$

and that for every complex $a$ and $b$ it possesses a unique solution satisfying the initial conditions $y(0) = a$ and $y'(0) = b$. This allows us to introduce the norming constants in the following way.

**Definition 2.2.** For an eigenvalue $\lambda_n$ of $T_{p,q}$, denote by $y_n$ the corresponding eigenfunction normalized by the initial conditions $y_n(0) = 0$ and $y_n'(0) = \lambda_n$. Then the quantity

$$\alpha_n := 2 \int_0^1 y_n^2(t) \, dt - 2 \int_0^1 p(t)y_n^2(t) \, dt$$

(2.1)

is called the norming constant corresponding to the eigenvalue $\lambda_n$.

Although this definition looks somewhat artificial, there is a good reason for defining the norming constants via (2.1). Firstly, for $p \equiv 0$, problem (1.1)–(1.2) becomes the spectral problem for the Sturm–Liouville operator $A$, and (2.1) agrees with the standard definition of the norming constant [13]. Secondly, denoting by $T_{p,q}'$ the $\lambda$-derivative of $T_{p,q}$, we find that

$$(T_{p,q}'(\lambda_n)y_n, y_n)_{L^2} = \lambda_n\alpha_n,$$

(2.2)

whence $\alpha_n$ determines the type of the eigenvalue $\lambda_n$, see [38]. In the following section, we shall transform the spectral problem for the operator pencil to that for some Dirac operator $\mathcal{D}(P)$, and (2.1) agrees with the standard definition of the norming constant for $\mathcal{D}(P)$. Next, we mention that the function $u(x, t) := y_n(x) \, e^{\lambda t}$ is a solution of the corresponding evolution equation $T_{p,q}(\frac{d}{dt})u = 0$, and its energy $(Au, u) + (u, u)$, with $\dot{u}$ denoting $\partial u/\partial t$, is equal to $\lambda_n^2 \alpha_n \, e^{2\lambda t}$.

**Remark 2.3.** Under assumption (A), all the norming constants $\alpha_n$ are positive. More generally, if $T_{p,q}$ is just strongly hyperbolic so that $T_{p,q}(\lambda_0) < 0$ for some $\lambda_0$ not necessarily equal to 0, then all the norming constants corresponding to the eigenvalues between 0 and $\lambda_0$ (if any) are negative, and the rest of the $\alpha_n$ are positive.

Both statements follow from (2.2) and the fact that $T_{p,q}'(\lambda) > 0$ for $\lambda > \lambda_0$ and $T_{p,q}'(\lambda) < 0$ for $\lambda < \lambda_0$ if $T_{p,q}(\lambda_0) < 0$, see [38].

We should also note that, conversely, if $A$ is invertible and all $\alpha_n$ are positive, then $A$ is positive, see [46].

Definition 2.4. Assume that $\lambda$ is an eigenvalue of the quadratic operator pencil $T_{p,q}$ and that $\alpha$ is the corresponding norming constant. Then $(\lambda, \alpha)$ is called the spectral eigenpair of $T_{p,q}$.

The spectral data $\text{sd}(T_{p,q})$ of the pencil $T_{p,q}$ is the set

$$\text{sd}(T_{p,q}) := \{ (\lambda, \alpha) \mid \lambda \in \sigma(T_{p,q}) \}$$

of all its spectral eigenpairs.

The inverse spectral problem of interest is to reconstruct the potentials $p$ and $q$ of the operator pencil $T_{p,q}$ given its spectral data $\text{sd}(T_{p,q})$. Some properties of spectral data for the class of quadratic pencils $T_{p,q}$ under consideration were established in [46]. Our aim in this paper is, firstly, to give a complete description of the set of the spectral data and, secondly, to find and justify an algorithm reconstructing the potentials $p$ and $q$ from the spectral data.

We observe that when $p \equiv 0$, the spectral problem for the operator pencil $T_{0,q}$ becomes the spectral problem $Ay = \lambda^2 y$ for the Sturm–Liouville operator $A$. Then $\lambda_{-n} = -\lambda_n$, $\alpha_{-n} = \alpha_n$, and $\alpha_n$ of (2.1) agrees with the standard definition of a norming constant [13]. For the Sturm–Liouville operator $A$ with a real-valued $q \in L_1(0, 1)$ and Robin boundary conditions, it was proved in [13] that the spectrum $(\lambda_n^2)_{n \in \mathbb{N}}$ of $A$ and the sequence $(\alpha_n)_{n \in \mathbb{N}}$ of the corresponding norming constants uniquely determine the potential $q$; the case of a distributional potential $q \in W^{-1}_2(0, 1)$ and various boundary conditions was treated in, e.g., [8, 20, 51]. The above references also give algorithms of reconstructing the potential $q$ from the spectral data of $A$.

The operator pencil $T_{p,q}$ contains two real-valued potentials $p$ and $q$ to be determined in the inverse problem; however, the spectral data of $T_{p,q}$ are twice as large as for a standard Sturm–Liouville operator. Therefore one may hope that the inverse spectral problem of reconstructing $p$ and $q$ from the spectral data of $T_{p,q}$ is well posed. Our first main result gives uniqueness of reconstruction.

Theorem 2.5. Under assumption (A), the operator pencil $T_{p,q}$ is uniquely determined by its spectral data $\text{sd}(T_{p,q})$.

It follows from [46, 44] (cf also the result of [12] for $p \in W^1_2(0, 1)$ and $q \in L_2(0, 1)$) that the spectral data for the operator pencils under consideration belong to the following set.

Definition 2.6. We denote by SD the family of all sets $\{(\lambda_n, \alpha_n)\}_{n \in \mathbb{Z}^+}$ consisting of pairs $(\lambda_n, \alpha_n)$ of real numbers satisfying the following properties:

(i) $\lambda_n$ are nonzero, strictly increase with $n \in \mathbb{Z}^+$, and have the representation $\lambda_n = \pi n + h + \tilde{\lambda}_n$ for some $h \in \mathbb{R}$ and a sequence $(\tilde{\lambda}_n)$ in $\ell_2(\mathbb{Z}^+)$;

(ii) $\alpha_n > 0$ for all $n \in \mathbb{Z}^+$ and the numbers $\tilde{\alpha}_n := \alpha_n - 1$ form an $\ell_2(\mathbb{Z}^+)$-sequence.

Our second result claims that, conversely, every element of SD forms spectral data for some operator pencil $T_{p,q}$ verifying assumption (A), i.e. with $p \in L_{2,0}(0, 1)$, $q \in W^{-1}_{2,0}(0, 1)$ and $A > 0$. In particular, it shows that conditions (i) and (ii) above give a complete description of the spectral data for the operator pencils $T_{p,q}$ satisfying (A).

Theorem 2.7. For every $\text{sd} \in \text{SD}$, there exists $p \in L_{2,0}(0, 1)$ and $q \in W^{-1}_{2,0}(0, 1)$ such that $A > 0$ and $\text{sd}$ are the spectral data for the operator pencil $T_{p,q}$.

The proof of this theorem is constructive and suggests the explicit reconstruction algorithm determining the potentials $p$ and $q$ from the set $\text{sd}$ belonging to SD; see section 7.

Our approach consists in reducing the spectral problem for $T_{p,q}$ to the one for a Dirac operator of a special form acting in $L_2(0, 1) \times L_2(0, 1)$, see section 3. Under a suitable unitary gauge transformation, this Dirac operator takes the ‘shifted’ Ablowitz–Kaup–Newell–Segur
Inverse Problems 28 (2012) 085008  R Hryniv and N Pronska

(AKNS) normal form [1]. For AKNS Dirac operators, the direct and inverse spectral problems are well understood, see [5, 11, 35]. We shall use the known methods to first reconstruct the Dirac operator in the ‘shifted’ AKNS form from the given data and then to transform this Dirac operator to the one that is directly associated with some pencil $T_{p,q}$. The latter gives the required solution of the inverse spectral problem of interest.

3. Reduction to the Dirac system

In this section we shall show that under the standing assumption (A) the spectral problem for the operator pencil $T_{p,q}$ can be reduced to the one for a special Dirac operator. We start with the following observation.

Lemma 3.1. Under the standing assumption (A), the equation $\ell(\gamma) = 0$ possesses a solution $\gamma$ that is strictly positive on $[0, 1]$.

Proof. The proof is divided into three steps.

Step 1. First we show that no non-trivial solution of the equation $\ell(\gamma) = 0$ possesses more than one zero on $[0, 1]$.

The proof is based on the fact that the quadratic form $a$ of the operator $A$ is positive due to assumption (A). Integration by parts shows that

$$a[\gamma] := (Ay, y)_{L^2} = \|\gamma\|^2 - 2\text{Re}(ry', y)_{L^2}$$

for $y \in \text{dom} A$. Next (cf [19]), the quadratic form $\text{Re}(ry', y)_{L^2}$ is relatively bounded with respect to the form

$$\tilde{a}[\gamma] := \|\gamma\|^2$$

with relative bound 0. Since the quadratic form $\tilde{a}$ is closed on the domain $\text{dom} \tilde{a} := \{ y \in W^2_2(0, 1) \mid y(0) = y(1) = 0 \}$, theorem VI.1.33 of [29] implies that the quadratic form $a$ is closed on the same domain.

Now we assume, in contrast, that a non-trivial solution $\gamma$ of the equation $\ell(y) = 0$ vanishes at two points $x_0$ and $x_1$, $0 \leq x_0 < x_1 \leq 1$. The zeros of $\gamma$ are isolated by [28, lemma 2.5]; therefore the function $z(x) := \begin{cases} y(x) & \text{for } x \in (x_0, x_1); \\ 0 & \text{for } x \notin (x_0, x_1) \end{cases}$ belongs to the domain of the quadratic form $a$ and is non-trivial. Moreover, integration by parts in the expression

$$a[z] = \int_{x_0}^{x_1} |y'(x)|^2 \, dx - 2 \text{Re} \int_{x_0}^{x_1} (ry')(x) \, dx$$

shows that $a[z] = 0$, which contradicts positivity of $a$. Therefore such a solution $\gamma$ cannot exist, thus establishing the claim.

Step 2. Denote by $y_0$ the solution of the equation $\ell(y) = 0$ satisfying the initial conditions $y(0) = 0$ and $y'(0) = 1$. Then $y_0$ does not vanish on $(0, 1)$ by step 1, so that in view of [28, lemma 2.5] we find that $y_0 > 0$ on $(0, 1]$.

Step 3. Consider the solution $y_1$ of the equation $\ell(y) = 0$ satisfying the terminal conditions $y(1) = y_0(1)$ and $y'(1) = y_0'(1) - 1$. Using again step 1 and lemma 2.5 of [28], one concludes that $y_1 > y_0$ over $[0, 1)$; therefore, this solution $y_1$ remains positive over the whole interval $[0, 1]$. The proof is complete.
Now we take a solution \( v \) of the equation \( \ell(y) = 0 \) that stays positive on \([0, 1]\) and set \( v' := y'/y \). Since \( y' = y^{[1]} + ry \in L_2(0, 1) \), the function \( v \) is in \( L_2(0, 1) \). Moreover, direct calculations show that \( q = v' + v^2 \) (so that \( q \) is a Miura potential, see [28]) and that the operator \( A \) can be written in the factorized form, namely

\[
Ay = -\left( \frac{d}{dx} + v \right) \left( \frac{d}{dx} - v \right) y.
\]  

(3.1)

We observe that there are many different \( v \) satisfying the Riccati equation \( v' + v^2 = q \) and thus allowing the above factorization of \( A \); we fix one such \( v \) in what follows and note that the distributional derivative of the function \( v - r \) is equal to \(-v^2\) and thus \( v - r \) is absolutely continuous.

For \( \lambda \neq 0 \) we can recast the spectral problem (1.1) as a first-order system for the functions \( u_2 := y \) and \( u_1 := (y' - vy)/\lambda \), namely

\[
u_2 - vu_2 = \lambda u_1,
\]

(3.2)

\[-u_1' - vu_1 + 2pu_2 = \lambda u_2.
\]

(3.3)

Setting

\[
J := \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad P := \begin{pmatrix} 0 & -v \\ -v & 2p \end{pmatrix}, \quad u = \begin{pmatrix} u_1 \\ u_2 \end{pmatrix},
\]

(3.4)

we see that the above system is the spectral problem \( \mathcal{D}(P)u = \lambda u \) for the Dirac operator \( \mathcal{D}(P) \) acting in \( L_2(0, 1) \times L_2(0, 1) \) via

\[
\mathcal{D}(P)u = J \frac{du}{dx} + Pu := : \ell(P)u
\]

(3.5)

on the domain

\[
\text{dom} \mathcal{D}(P) := \{ u = (u_1, u_2)^t \in W^1_2(0, 1) \times W^1_2(0, 1) \mid u_2(0) = u_2(1) = 0 \}.
\]

**Lemma 3.2.** The nonzero spectra of the Dirac operator \( \mathcal{D}(P) \) and the operator pencil \( T_{p,q} \) coincide.

**Proof.** We start by observing that the Dirac operator \( \mathcal{D}(P) \) is self-adjoint in the Hilbert space \( L_2(0, 1) \times L_2(0, 1) \) and has a simple discrete spectrum [35]. The above arguments show that every eigenvalue \( \lambda \) of \( T_{p,q} \) is an eigenvalue of \( \mathcal{D}(P) \) as well.

Conversely, assume that \( \lambda \neq 0 \) is an eigenvalue of \( \mathcal{D}(P) \) and \( u = (u_1, u_2)^t \) is a corresponding eigenfunction. Determining \( u_1 \) via \( u_2 \) from (3.2) and substituting in (3.3), we find that \( y := u_3 \) satisfies the equality

\[-\lambda \left( \frac{d}{dx} + v \right) \left( \frac{d}{dx} - v \right) y - 2py = \lambda y,
\]

which in view of (3.1) yields \( T_{p,q}y = 0 \). Clearly, \( y \) is non-trivial and satisfies the Dirichlet boundary conditions; henceforth, it is an eigenfunction of \( T_{p,q} \) corresponding to the eigenvalue \( \lambda \).

**Remark 3.3.** A straightforward analysis of (3.2) and (3.3) shows that \( \lambda = 0 \) is an eigenvalue of the Dirac operator \( \mathcal{D}(P) \), the corresponding eigenfunction being \( u = (u_1, u_2)^t \) with \( u_1 = \exp \left(- \int v \right) \) and \( u_2 \equiv 0 \). However, under assumption (A) the number \( \lambda = 0 \) is never an eigenvalue of \( T_{p,q} \); therefore,

\[
\sigma(\mathcal{D}(P)) = \sigma(T_{p,q}) \cup \{0\}.
\]
The norming constant for the Dirac operator $\mathcal{D}(P)$ corresponding to an eigenvalue $\lambda$ is defined as
\[ \|u\|^2 = \|u_1\|_{L^2}^2 + \|u_2\|_{L^2}^2, \]
where $u = (u_1, u_2)^T$ is the eigenfunction for $\lambda$ normalized by the initial conditions $u_1(0) = 1$ and $u_2(0) = 0$. Assume that $\lambda \neq 0$; then, as shown in the proof of lemma 3.2, $y := u_2$ is an eigenfunction of $T_{p,q}$ corresponding to the eigenvalue $\lambda$; note also that $y$ is real valued and satisfies the initial conditions $y(0) = 0$ and $y(0) = (y' - ry)(0) = (y' - vy)(0) = \lambda u_1(0) = \lambda$. Integration by parts on account of (3.1) gives
\[ \|u_2 - yu_2\|_{L^2}^2 = (Au_2, u_2)_{L^2}; \]
using now (3.2), we conclude that
\[ \|u\|^2 = \frac{1}{\lambda^2} (Ay, y)_{L^2} + (y, y)_{L^2} = -\frac{2}{\lambda} (By, y)_{L^2} + 2(y, y)_{L^2}, \]
which coincides with (2.1). We have thus established the following important result.

**Lemma 3.4.** The norming constants corresponding to nonzero eigenvalues of the Dirac operator $\mathcal{D}(P)$ and the operator pencil $T_{p,q}$ coincide.

The above lemma suggests that we can use the spectral data $\text{sd}(T_{p,q})$ of the operator pencil $T_{p,q}$ in order to find the related Dirac operator $\mathcal{D}(P)$. Having determined the potential $P = (p_{ij})_{i,j=1}^2$ of $\mathcal{D}(P)$, we then identify the potentials $p$ and $q$ of the operator pencil $T_{p,q}$ as $p := p_{22}/2$ and $q := -p'_{12} + p_{12}$. We note, however, that since the factorization (3.1) is not unique, there are many Dirac operators $\mathcal{D}(P)$ associated with $T_{p,q}$. Therefore the spectral data $\text{sd}(T_{p,q})$ cannot determine such an operator $\mathcal{D}(P)$ uniquely.

The reason for this non-uniqueness is quite clear from remark 3.3 and lemma 3.4; indeed, the spectral data for $T_{p,q}$ leave the norming constant $a_0$ for the eigenvalue $\lambda_0 := 0$ of $\mathcal{D}(P)$ undetermined. It is this freedom in the choice of $a_0$ that leads to non-uniqueness of potentials $P$ for the associated Dirac operators $\mathcal{D}(P)$. However, we shall show in section 6 that all such Dirac operators determine the same pencil $T_{p,q}$.

4. **Transformation operators**

The relation between the operator pencil $T_{p,q}$ and the Dirac operator $\mathcal{D}(P)$ of (3.4) and (3.5) explained in the previous section suggests that we can use the well-developed inverse spectral theory for Dirac operators to reconstruct $\mathcal{D}(P)$ from the given spectral data. Once such a Dirac operator has been found, it is then straightforward to determine the corresponding potentials $p$ and $q$ of the pencil $T_{p,q}$.

However, the classical inverse spectral theory reconstructs a Dirac operator with potential in the AKNS form or in other canonical form, see section 5. Therefore, we then have to transform such a canonical Dirac operator to the Dirac operator of the form (3.4) keeping the spectral data unchanged. This is done by means of the so-called transformation operators, which we study in this section.

More exactly, assume that $P$ and $Q$ are $2 \times 2$ matrix-valued potentials in $L^2((0, 1), \mathcal{M}_2)$ and set
\[ D_0 := \{(u_1, u_2)^\dagger \in W^1_2(0, 1) \times W^1_2(0, 1) \mid u_2(0) = 0\}. \]
We need a transformation operator $\mathcal{X} = \mathcal{X}(P, Q)$ between the Dirac operators $\ell(P)$ and $\ell(Q)$ acting on the set $D_0$, i.e. an operator satisfying the relation $\mathcal{X} \ell(P)u = \ell(Q)\mathcal{X}u$ for all $u \in D_0$. Such transformation operators for $P$ and $Q$ with Lipschitz continuous entries were...
constructed in [9, 35]; it is thus reasonable to look for the transformation operator \( \mathcal{X} \) of a similar form

\[
\mathcal{X} \mathbf{u}(x) = R(x) \mathbf{u}(x) + \int_0^x K(x, s) \mathbf{u}(s) \, ds,
\]

where \( R \) and \( K \) are the \( 2 \times 2 \) matrix-valued functions of one and two variables, respectively. Keeping in mind that the Dirac operators of interest, \( \ell (P) \) and \( \ell (Q) \), are considered on functions satisfying the same initial conditions, we impose the restriction \( R(0) = I \) guaranteeing that \( \mathcal{X} \) preserves the values of functions at \( x = 0 \). Under such a normalization, \( R \) will explicitly be given as

\[
R(x) = e^{\theta_0(x)} \begin{pmatrix} \cos \theta_2(x) & \sin \theta_2(x) \\ -\sin \theta_2(x) & \cos \theta_2(x) \end{pmatrix} = e^{\theta_1(x)I + \theta_2(x)J},
\]

with

\[
\begin{align*}
\theta_1(x) &= \frac{1}{2} \int_0^x \text{tr}[JQ(s) - P(s))] \, ds, \\
\theta_2(x) &= \frac{1}{2} \int_0^x \text{tr}(Q(s) - P(s)) \, ds,
\end{align*}
\]

cf [9]. More exactly, the following analogue of theorem 3.1 of [9] holds true.

**Theorem 4.1.** Assume that \( P \) and \( Q \) are in \( L_2((0, 1), M_2) \). Then an operator \( \mathcal{X} (P, Q) \) of the form (4.1), with \( R \) obeying the condition \( R(0) = I \) and with a summable kernel \( K \), is a transformation operator for \( \ell (P) \) and \( \ell (Q) \) on the set \( D_0 \) if and only if the matrix-valued function \( R \) is given by (4.2) and (4.3) and the kernel \( K = (K_{ij})_{i,j=1}^2 \) is a mild solution of the partial differential equation

\[
J \partial_y K(x, y) + \partial_x K(x, y)J = K(x, y)P(y) - Q(x)K(x, y)
\]

in the domain \( \Omega := \{(x, y) \mid 0 < y < x < 1 \} \) satisfying for \( 0 \leq x \leq 1 \) the boundary conditions

\[
K(x, 0)J - JK(x, x) = JR(x) + Q(x)R(x) - R(x)P(x),
\]

\[
K_{12}(x, 0) = K_{22}(x, 0) = 0.
\]

The proof of this theorem follows in general that of theorem 3.1 of [9]. One essential difference is that since the matrix-valued functions \( P \) and \( Q \) are less regular, \( K \) need not be differentiable in the usual sense. Therefore differentiation of \( K \) should be understood in the distributional sense; that is why \( K \) is only required to be a mild solution of (4.4). For the sake of completeness, we justify the steps involving differentiation in the proof below.

**Proof.** Firstly, we observe that, for an integrable \( K \) and for \( \mathbf{u} \in D_0 \), the standard formula

\[
\frac{d}{dx} \int_0^x K(x, s) \mathbf{u}(s) \, ds = K(x, x) \mathbf{u}(x) + \int_0^x \partial_x K(x, s) \mathbf{u}(s) \, ds
\]

remains to hold in the sense of distributions, so that

\[
\ell (Q) \mathcal{X} \mathbf{u}(x) = JR(x) \mathbf{u}'(x) + [J\dot{R}(x) + Q(x)R(x)] \mathbf{u}(x)
\]

\[
+ J \int \frac{d}{dx} \int_0^x K(x, s) \mathbf{u}(s) \, ds + \int_0^x Q(x)K(x, s) \mathbf{u}(s) \, ds
ds = JR(x) \mathbf{u}'(x) + [J\dot{R}(x) + Q(x)R(x) + JK(x, x)] \mathbf{u}(x)
\]

\[
+ \int_0^x [J\partial_x K(x, s) + Q(x)K(x, s)] \mathbf{u}(s) \, ds.
\]

(4.7)
Similarly, an integration by parts formula
\[\int_0^t K(x,s)u'(s) \, ds = K(x, x)u(x) - K(x, 0)u(0) - \int_0^t \partial_x K(x, s)u(s) \, ds\]
holds in the distributional sense, and in the same sense one obtains the equalities
\[\mathcal{E} \ell_0(P)u(x) = R(x)Ju'(x) + R(x)P(x)u(x)\]
\[+ \int_0^t K(x, s)[Ju'(s) + P(s)u(s)] \, ds\]
\[= R(x)Ju'(x) + \{R(x)P(x) + K(x, x)\}u(x)\]
\[- K(x, 0)Ju(0) + \int_0^t \{K(x, s)P(s) - \partial_x K(x, s)\}u(s) \, ds.\] (4.8)

If \( R \) is given by (4.2) and \( K \) satisfies (4.6), then \( JR = RJ \) and \( K(x, 0)Ju(0) = 0 \) for \( u \in D_0 \); using now (4.4) and (4.5) in equations (4.7) and (4.8), we arrive at the equality
\[\ell(Q)Ku = E \ell_0(P)u\]
on the domain \( D_0 \), thus establishing the sufficiency part.

To prove necessity, we equate the integrands and the coefficients of \( u \) and \( u' \) in (4.7) and (4.8). The coefficients of \( u' \) yield the relation \( JR = RJ \) and so
\[R(x) = \begin{pmatrix} a(x) & b(x) \\ -b(x) & a(x) \end{pmatrix}.\]
Now equate the coefficients of \( u \) to obtain the relation
\[JR'(x) + Q(x)R(x) - R(x)P(x) = K(x, x)J - JK(x, x)\] (4.9)
coinciding with (4.5). Using the fact that \( KJ - JK \) and \( JKJ + K \) have zero traces, we derive from (4.9) the following system for \( a \) and \( b \):
\[2 \frac{d}{dx} \begin{pmatrix} a \\ b \end{pmatrix} = \begin{pmatrix} \text{tr}J(Q - P) & -\text{tr}(Q - P) \\ \text{tr}(Q - P) & \text{tr}J(Q - P) \end{pmatrix} \begin{pmatrix} a \\ b \end{pmatrix}.\] (4.10)
Multiplying the first row by \( a \) and the second by \( b \) and adding gives
\[(a^2 + b^2)' = (a^2 + b^2) \text{tr}J(Q - P),\]
so that \( a^2 + b^2 = c \exp(2\theta_1) \) with \( \theta_1 \) of (4.3) and some constant \( c \). Recalling the assumption \( R(0) = I \), we conclude that \( c = 1 \).

Now, upon substituting \( a = \exp(\theta_1) \cos \eta \) and \( b = \exp(\theta_1) \sin \eta \) in the system (4.10), we find that \( \eta = \theta_2 + \theta_1 \) with a constant \( \theta_1 \). Using again the normalization \( R(0) = I \), we obtain \( \eta = \theta_2 + 2\pi n, n \in \mathbb{Z} \). Thus the matrix \( R \) is indeed given by (4.2).

Next, the equation for the kernel \( K \) follows from the equality of the integrands in (4.7) and (4.8). Finally, as the term \( K(x, 0)Ju(0) \) must vanish for all \( u \in D_0 \), relation (4.6) follows. The proof is complete. \( \square \)

The above theorem reduces the question on existence of the transformation operator to that on solvability of the system (4.4)–(4.6). Existence of mild solutions to that system is discussed in the next theorem.

**Theorem 4.2.** Assume that the matrix-valued functions \( P \) and \( Q \) are in \( L_2((0, 1), \mathcal{M}_2) \). Then the system (4.4)–(4.6) has a unique solution in the sense of distributions; moreover, this solution belongs to \( L_2(\Omega, \mathcal{M}_2) \).
Proof. The proof of this theorem is rather standard and uses reduction to the equivalent system of integral equations. We only sketch the main idea and refer the reader to the paper [57] where the missing details can be found.

Introduce a four-component vector-function \( L = (L_1, L_2, L_3, L_4)^t \) via

\[
L_1 = K_{21} - K_{12}, \quad L_2 = K_{22} - K_{11}, \quad L_3 = K_{11} + K_{22}, \quad L_4 = K_{12} + K_{21}.
\]

In terms of this vector, the system (4.4) takes the form

\[
(\partial_x + E \partial_y)L(x, y) = F(x, y)L(x, y),
\]

where \( E = \text{diag}(1, -1, 1, -1) \) and \( F(x, y) \) is a \( 4 \times 4 \) matrix-function whose entries are linear combinations of the entries of \( P(y) \) and \( Q(x) \). The boundary conditions (4.5) and (4.6) for \( K \) translate into the relations

\[
L_k(x, x) = g_k(x), \quad k = 2, 4,
\]

\[
L_2(x, 0) = L_4(x, 0)
\]

\[
L_3(x, 0) = -L_2(x, 0),
\]

where \( g_2 \) and \( g_4 \) are respectively the \( (1, 2) \) and \( (1, 1) \) entries of the matrix \( R(x)P(x) - Q(x)R(x) - iR'(x) \). Under the assumptions of the theorem, \( g_2 \) and \( g_4 \) belong to \( L_2(0, 1) \).

We next denote by \( F_i, i = 1, 4 \), the \( i \)th row of the matrix \( F \) and rewrite the system (4.11)–(4.12) as a system of the integral equations

\[
L_i = \int_0^y F_i(-s + x + y, s)L(-s + x + y, s)\, ds + g_i \left( \frac{x + y}{2} \right), \quad i = 2, 4
\]

\[
L_1 = \int_0^y F_1(s + x - y, s)L(s + x - y, s)\, ds
\]

\[
+ \int_0^y F_2(-s + x - y, s)L(-s + x - y, s)\, ds + g_2 \left( \frac{x - y}{2} \right)
\]

\[
L_3 = \int_0^y F_3(s + x - y, s)L(s + x - y, s)\, ds
\]

\[
- \int_0^y F_4(-s + x - y, s)L(-s + x - y, s)\, ds - g_4 \left( \frac{x - y}{2} \right).
\]

Applying to the latter the successive approximation method and using the fact that \( g_2 \) and \( g_4 \) belong to \( L_2(0, 1) \), one proves the existence of a unique solution \( L \) belonging to \( L_2(\Omega, \mathcal{C}^4) \). This gives a unique mild solution \( K \) of the original hyperbolic system (4.4)–(4.6) and shows that \( K \in L_2(\Omega, \mathcal{M}_2) \).

Throughout the rest of the paper, we shall assume that the matrix-valued potentials \( P \) and \( Q \) are Hermitian, i.e. \( P^*(x) = P(x) \) and \( Q^*(x) = Q(x) \) a.e. on \([0, 1]\). Then the corresponding Dirac operators \( D(P) \) and \( D(Q) \) are self-adjoint and have simple discrete spectra. Moreover, the eigenvalues \( \mu_n(P) \) of \( D(P) \) can be labelled by \( n \in \mathbb{Z} \) so that \( \mu_n = \pi n + \frac{1}{2} \int trP + o(1) \) as \( |n| \to \infty \) (see [35]), and similarly for the eigenvalues of \( D(Q) \).

Just as for an operator pencil \( T_{p,q} \), we define the spectral data for a Dirac operator \( D \) as the set \( \{ (\lambda, \alpha) \mid \lambda \in \sigma(D) \} \) of all eigenpairs \( (\lambda, \alpha) \) composed of eigenvalues \( \lambda \) and the corresponding norming constants \( \alpha \). We denote by \( \text{sd}(P) \) (resp. \( \text{sd}(Q) \)) the spectral data of \( D(P) \) (resp. the spectral data of \( D(Q) \)).

Also, \( \mathcal{X} = \mathcal{X}(P, Q) \) will stand for the transformation operator of the form (4.1) for the differential expressions \( \ell(P) \) and \( \ell(Q) \) on the domain \( \mathcal{D}_0 \), with \( R \) given by (4.2) and (4.3). We
shall write $\mathcal{X} = \mathcal{R} + \mathcal{N}$, where $\mathcal{R} u(x) := R(x)u(x)$ is the operator of multiplication by $R$ and

$$\mathcal{N} u(x) := \int_0^x K(x, s)u(s) \, ds$$

is the corresponding integral operator. It will essentially be used in the reconstruction procedure of the following section.

We enumerate the eigenpairs in $K$:

$$\lambda, u \in \mathbb{R}$$

The sequences $(\lambda_n)_{n \in \mathbb{Z}}$ and $(u_n)_{n \in \mathbb{Z}}$ belong to $(\mathcal{R} + \mathcal{N})$ and thus the operator $\mathcal{N}$ is an integral operator with lower triangular kernel. On the other hand, the operator $\mathcal{R}$ is upper triangular, i.e.

$$\mathcal{R} u(x) := \int_0^x R(x)u(s) \, ds$$

is the corresponding integral operator. We observe that for the Hermitian operators $\mathcal{P}$ and $\mathcal{Q}$ the functions $i\theta_1$ and $\theta_2$ are real valued; in particular, the operator $\mathcal{P}$ is unitary.

Before discussing further properties of the transformation operator $\mathcal{X}$, the following simple but useful remark seems in place.

**Remark 4.3.** Since the transformation operator $\mathcal{X}$ intertwines the Dirac differential expressions $\ell(P)$ and $\ell(Q)$, it is straightforward to see that the relation

$$(\ell(P) - \lambda) u = f$$

holds if and only if for $v := \mathcal{R} u$ and $g := \mathcal{X} f$ one obtains

$$(\ell(Q) - \lambda) v = g.$$

**Lemma 4.4.** Assume that $P$ and $Q$ are Hermitian and that $\text{sd}(P) = \text{sd}(Q)$. Then the integral operator $\mathcal{N}$ in the transformation operator $\mathcal{X} = \mathcal{X}(P, Q)$ is the zero operator.

**Proof.** We enumerate the eigenpairs in $\text{sd}(P) = \text{sd}(Q)$ as $(\lambda_n, \alpha_n)$ for $n \in \mathbb{Z}$ and denote by $u_n$ the eigenfunction of the operator $\mathcal{D}(P)$ corresponding to the eigenvalue $\lambda_n$ and normalized via

$$u_n(0) = (1, 0)^T.$$ Then $v_n := \mathcal{X}(P, Q)u_n$ is the corresponding eigenfunction for the operator $\mathcal{D}(Q)$ satisfying the same initial condition.

The sequences $(u_n)_{n \in \mathbb{Z}}$ and $(v_n)_{n \in \mathbb{Z}}$ form orthogonal bases of the Hilbert space $L_2((0, 1), \mathbb{C}^2)$; moreover, $\|u_n\| = \|v_n\| = \sqrt{\alpha_n}$. Thus we conclude that the operator $\mathcal{X}$ is unitary, i.e.

$$(\mathcal{R} + \mathcal{N})^*(\mathcal{R} + \mathcal{N}) = \mathcal{I},$$

where $\mathcal{I}$ is the identity operator in $L_2((0, 1), \mathbb{C}^2)$. Since $\mathcal{R}$ is unitary, the last equality may be rewritten as

$$(\mathcal{I} + \mathcal{R}^{-1} \mathcal{N})^*(\mathcal{I} + \mathcal{R}^{-1} \mathcal{N}) = \mathcal{I}.$$ We recall that $\mathcal{N}$ (and thus $\mathcal{R}^{-1} \mathcal{N}$) is an integral operator with lower triangular kernel belonging to $L_2(\Omega, \mathcal{N}_2)$. Slightly modifying the arguments of [47, section IV.1], one sees that $\mathcal{R}^{-1} \mathcal{N}$ is a Volterra operator, whence the inverse $(\mathcal{I} + \mathcal{R}^{-1} \mathcal{N})^{-1}$ exists and is given by the Neumann series

$$(\mathcal{I} + \mathcal{R}^{-1} \mathcal{N})^{-1} = \mathcal{I} - \mathcal{R}^{-1} \mathcal{N} + (\mathcal{R}^{-1} \mathcal{N})^2 + \cdots = \mathcal{I} + \mathcal{N},$$

with $\mathcal{N}$ being an integral operator with lower triangular kernel. On the other hand, the operator $(\mathcal{R}^{-1} \mathcal{N})^*$ is an integral operator with upper triangular kernel, and the relations

$$\mathcal{I} + \mathcal{R}^{-1} \mathcal{N}^* = (\mathcal{I} + \mathcal{R}^{-1} \mathcal{N})^{-1} = \mathcal{I} + \mathcal{N}^*$$

imply that $(\mathcal{R}^{-1} \mathcal{N})^* = \mathcal{N} = 0$. Therefore $\mathcal{X} = 0$, and the proof is complete.

The following theorem gives necessary and sufficient conditions on transformation operators $\mathcal{X}(P, Q)$ in order that the Dirac operators $\mathcal{D}(P)$ and $\mathcal{D}(Q)$ should have the same spectral data. It will essentially be used in the reconstruction procedure of the following section.
Theorem 4.5. Assume that the matrix potentials $P$ and $Q$ are Hermitian. Then the spectral data for the operators $\mathcal{D}(P)$ and $\mathcal{D}(Q)$ coincide, i.e. $\text{sd}(P) = \text{sd}(Q)$, if and only if the transformation operator $X(P, Q)$ for $\ell(P)$ and $\ell(Q)$ on the domain $\mathcal{D}_0$ only contains the unitary part $\mathcal{R}$ (i.e. $X = 0$) and $\theta_2(1) = \pi n$ for some $n \in \mathbb{Z}$.

Proof. Necessity. If the spectral data for the operators $\mathcal{D}(P)$ and $\mathcal{D}(Q)$ coincide, then $X = 0$ by lemma 4.4 and thus $\mathcal{D}(P, Q) = \mathcal{R}$. Take an arbitrary eigenvalue $\lambda$ of $\mathcal{D}(P)$ and denote by $u = (u_1, u_2)^t$ the corresponding eigenfunction. Then

$$v(x) := \mathcal{R}u = \exp(\theta_1(x)) \begin{pmatrix} \cos \theta_2(x) u_1(x) + \sin \theta_2(x) u_2(x) \\ -\sin \theta_2(x) u_1(x) + \cos \theta_2(x) u_2(x) \end{pmatrix}$$

is the eigenfunction for the operator $\mathcal{D}(Q)$ corresponding to the same eigenvalue $\lambda$. Observe now that the second components of $u(1)$ and $v(1)$ are equal to zero. Since $v(1) = \exp(\theta_1(1)) \begin{pmatrix} \cos \theta_2(1) u_1(1) \\ -\sin \theta_2(1) u_1(1) \end{pmatrix}$ and $u_1(1) \neq 0$, we conclude that $\sin \theta_2(1) = 0$, and thus $\theta_2(1) = \pi n$ for an integer $n$ as claimed. This completes the proof of the necessity parts.

Sufficiency. Suppose that $\mathcal{D}(P, Q) = \mathcal{R}$ and that $\lambda$ is an eigenvalue of the operator $\mathcal{D}(P)$ with a corresponding eigenfunction $u$. Consider the vector $v = \mathcal{R}u$; then $\ell(Q)v = \lambda v$. The assumption $\theta_2(1) = \pi n$ for an integer $n$ implies that $R(1)$ is a multiple of the identity matrix $I$. Since also $R(0) = I$, we conclude that the second component $v_2$ of $v$ vanishes at both endpoints and thus $v \in \text{dom} \mathcal{D}(Q)$.

The above implies that the spectrum of $\mathcal{D}(P)$ is contained in the spectrum of $\mathcal{D}(Q)$. As $\mathcal{R}$ is boundedly invertible, the roles of $P$ and $Q$ can be interchanged, thus showing that the spectra of the operators coincide. Finally, since the operator $\mathcal{R}$ is unitary and preserves the initial conditions, the norming constants for $\mathcal{D}(P)$ and $\mathcal{D}(Q)$ are equal, i.e. $\text{sd}(P) = \text{sd}(Q)$.

The proof is complete. \hfill $\square$

5. Reconstruction of the pencil: existence

Our aim in this section is to prove theorem 2.7 on existence of a pencil $T_{p,q}$ with potentials $p \in L_2(0, 1)$ and $q \in W^{-1}_2(0, 1)$ having the prescribed element $\text{sd}$ of SD as its spectral data. The uniqueness of reconstruction will be dealt with in the following section.

Outline of the proof of theorem 2.7. First, we construct a Dirac operator $\mathcal{D}(Q)$ in the ‘shifted’ AKNS form whose nonzero spectrum and corresponding norming constants are given by $\text{sd}$. Then we use the transformation operator technique to transform $\mathcal{D}(Q)$ to another Dirac operator $\mathcal{D}(P)$ with the same spectral data and with potential $P = (p_{ij})$ of the form (3.4). Setting then

$$p := \frac{p_{22}}{2}, \quad q := -p'_{12} + p_{12}^2$$

and recalling the results of section 3, we conclude that the operator pencil $T_{p,q}$ is a solution of the inverse spectral problem. Moreover, as $q$ is a Miura potential [28], the operator $\mathcal{A}$ is positive, i.e. the pencil $T_{p,q}$ verifies assumption (A).

The rest of this section contains details of constructing the potential $Q$ of the ‘shifted’ AKNS form and transforming it to a $P$ of the form (3.4).
We start with taking an arbitrary set \( sd = \{(\lambda_n, \alpha_n)\} \) in \( SD \). The enumeration of \( \lambda_n \) is uniquely determined by the requirement that \( \lambda_{-1} < 0 \) and \( \lambda_1 > 0 \) and fixes the number \( h \) in the asymptotic representation of part (i) of definition 2.6. We then take an arbitrary \( \alpha_0 > 0 \), put \( \lambda_0 := 0 \) and augment the set \( sd \) with \((\lambda_0, \alpha_0)\) to become \( sd^* \).

Now we recall the following facts from the inverse spectral theory for AKNS Dirac operators, see [5, 35]. Denote by \( Q_0 \) the set of \( 2 \times 2 \) matrix-valued functions \( Q_0 \) of the AKNS normal form, namely

\[
Q_0 := \left\{ Q_0 = \begin{pmatrix} q_1 & q_2 \\ q_2 & -q_1 \end{pmatrix} \mid q_j \in L_{2,R}(0, 1) \right\}.
\]

For \( Q_0 \in Q_0 \), the Dirac operator \( \mathcal{D}(Q_0) \) is self-adjoint, has a simple discrete spectrum and its eigenvalues can be enumerated as \( \lambda_n(Q_0) \), \( n \in \mathbb{Z} \), so that \( \lambda_n(Q_0) \) increase with \( n \) and \( \lambda_n(Q_0) = \pi n + \lambda_n(Q_0) \), with an \( \ell_2(\mathbb{Z}) \)-sequence \( (\lambda_n) \). The corresponding norming constants \( \alpha_n(Q_0) \) are positive and the remainders \( \tilde{\alpha}_n(Q_0) := \alpha_n(Q_0) - 1 \) form an \( \ell_2(\mathbb{Z}) \)-sequence.

Conversely, it follows from the results of [5, 53] that every set \( \{(\lambda_n, \alpha_n)\}_{n \in \mathbb{Z}} \) with \( \lambda_n \) and \( \alpha_n \) possessing the above properties is the set of spectral data for a unique AKNS Dirac operator \( \mathcal{D}(Q_0) \) with \( Q_0 \in Q_0 \).

The set \( sd^* \) (i.e. the set \( sd \) augmented with the pair \((\lambda_0, \alpha_0)\) as above) has all the properties of the spectral data for an AKNS Dirac operator save that the asymptotics of \( \lambda_n \) is shifted by some number \( h \), cf the definition of the set \( SD \). For \( h \in \mathbb{R} \), we denote by

\[
Q_h := \{ Q_0 + hl | Q_0 \in Q_0 \}
\]

the set of \( h \)-shifted AKNS matrix potentials; then the following holds true.

**Proposition 5.1.** For an arbitrary \( sd \in SD \), fix \( h \in \mathbb{R} \) in the representation of (i) in definition 2.6 so that \( \lambda_{-1} < 0 \) and \( \lambda_1 > 0 \), and denote by \( sd^* \) augmentation of \( sd \) by a pair \((\lambda_0, \alpha_0)\), with \( \lambda_0 := 0 \) and a positive \( \alpha_0 \). Then there exists a unique potential \( Q \in Q_h \) such that \( sd^* \) gives the spectral data for the Dirac operator \( \mathcal{D}(Q) \).

For an arbitrary \( Q \in L_2((0, 1) \times M_2) \), we introduce the set

\[
\text{Iso}(Q) := \{ \tilde{Q} \in L_2((0, 1), M_2) \mid sd(\tilde{Q}) = sd(Q) \}
\]

of potentials *isospectral* with a given \( Q \) and denote by \( \mathcal{P} \) the set of all potentials of the form (3.4), i.e.

\[
\mathcal{P} := \{ P = (p_{ij})_{i,j=1}^2 \mid p_{ij} \in L_{2,R}(0, 1), \ p_{11} = 0, \ p_{12} = p_{21} \}.
\]

The following result is crucial in constructing a pencil \( T_{p,q} \) with the given spectral data.

**Theorem 5.2.** Assume that \( Q \in Q_h \) is such that \( \lambda = 0 \) is an eigenvalue of the Dirac operator \( \mathcal{D}(Q) \). Then there exists a unique \( P \in \mathcal{P} \) such that \( \text{Iso}(Q) \cap \mathcal{P} = \{P\} \).

**Proof.** We divide the proof into three steps. First we prove that there is a unique \( P \in \mathcal{P} \) with the property that the transformation operator \( \mathcal{E}(P, Q) \) between \( \mathcal{E}(P) \) and \( \mathcal{E}(Q) \) on \( D_0 \) is just the operator \( \mathcal{R} \) of multiplication by the matrix-valued function \( R \) of (4.2) and (4.3). In the second step, we show that this \( P \) is indeed isospectral with \( Q \). Finally, we explain why there is no other potential in \( \text{Iso}(Q) \cap \mathcal{P} \).

**Step 1.** We write \( Q \in Q_h \) as

\[
Q = hl + \begin{pmatrix} q_1 & q_2 \\ q_2 & -q_1 \end{pmatrix}
\]
with real-valued \( q_1 \) and \( q_2 \) in \( L_2(0, 1) \). Let \( \theta \) be an absolutely continuous function and \( R = e^{\theta J} \); then \( R \) commutes with \( J \) and one finds that
\[
R^{-1} \left( J \frac{d}{dx} + Q \right) R = J \frac{d}{dx} + R^{-1} J R' + R^{-1} Q R.
\]
Therefore \( \hat{\mathcal{R}} \ell(P) = \ell(Q) \hat{\mathcal{R}} \) for a unique matrix potential \( P \) equal to
\[
P = R^{-1} J R' + R^{-1} Q R
\]
\[
= (h - \theta') I + \begin{pmatrix} q_1 \cos 2\theta - q_2 \sin 2\theta & q_1 \sin 2\theta + q_2 \cos 2\theta \\ q_1 \sin 2\theta + q_2 \cos 2\theta & -q_1 \cos 2\theta + q_2 \sin 2\theta \end{pmatrix}.
\]
(5.3)
The potential \( P \) defined by (5.3) belongs to the set \( \mathcal{P} \) if and only if
\[
-\theta' + q_1 \cos 2\theta - q_2 \sin 2\theta + h = 0.
\]
(5.4)
There exists a unique solution of this equation over \([0, 1]\) satisfying the initial condition \( \theta(0) = 0 \). We call this solution \( \theta_1 \) and determine the corresponding potential \( P \in \mathcal{P} \) through (5.3) with \( \theta = \theta_1 \). A straightforward calculation shows that this \( \theta_2 \) satisfies relations (4.3); in particular, \( \theta_2 = h - \frac{1}{2} \theta_{22} \). By theorem 4.1, the operator \( \hat{\mathcal{R}} \) of multiplication by the matrix-valued function \( R = e^{\theta J} \) of (4.2) is indeed the transformation operator between \( \ell(P) \) and \( \ell(Q) \) on \( D_0 \).

Step 2. Next we claim that \( \theta_2(1) = \pi n \) for some \( n \in \mathbb{Z} \). By construction, \( \hat{\mathcal{R}}^{-1} \ell(Q) \hat{\mathcal{R}} = \ell(P) \), so that the operator \( \hat{\mathcal{R}}(P) := \hat{\mathcal{R}}^{-1} \hat{\mathcal{R}}(Q) \hat{\mathcal{R}} \) is a Dirac operator defined via \( \hat{\mathcal{R}}(P) u = \ell(P) u \) on the domain consisting of those \( u = (u_1, u_2)^t \in L_2((0, 1), \mathbb{C}^2) \) for which \( \hat{\mathcal{R}} u \in \text{dom} \hat{\mathcal{R}}(Q) \).
The assumption that \( \lambda = 0 \) is an eigenvalue of the Dirac operator \( \hat{\mathcal{R}}(Q) \) and the similarity of \( \hat{\mathcal{R}}(Q) \) and \( \hat{\mathcal{R}}(P) \) implies that \( \lambda = 0 \) is in the spectrum of \( \hat{\mathcal{R}}(P) \), and we denote by \( u^0 = (u_1, u_2)^t \) the corresponding eigenfunction. As \( R(0) = I \) and \( v^0 = (v_1, v_2)^t := \hat{\mathcal{R}} u^0 \) is in the null-space of \( \hat{\mathcal{R}}(Q) \), we see that \( u_2(0) = v_2(0) = 0 \), and thus \( u_2(1) = 0 \) by (3.2). Therefore,
\[
v^0(1) = R(1) u^0(1) = \begin{pmatrix} u_1(1) \cos \theta_2(1) \\ -u_1(1) \sin \theta_2(1) \end{pmatrix}.
\]
As \( u_1(1) \neq 0 \) and \( v_2(1) = 0 \), we conclude that \( \sin \theta_2(1) = 0 \) and thus that \( \theta_2(1) = \pi n \) for some \( n \in \mathbb{Z} \).

Henceforth, we have constructed a potential \( P \in \mathcal{P} \) and a unitary operator \( \hat{\mathcal{R}} \) of the form (4.2) and (4.3) with \( \theta_2(1) = \pi n \) for some \( n \in \mathbb{Z} \) so that \( \hat{\mathcal{R}} \) is the transformation operator between \( \ell(P) \) and \( \ell(Q) \) on \( D_0 \). By theorem 4.5, \( P \) then belongs to \( \text{Iso}(Q) \).

Step 3. Finally, suppose there is another \( P_1 \) in the set \( \text{Iso}(Q) \cap \mathcal{P} \). By theorem 4.5, the transformation operator \( \hat{\mathcal{R}}(P_1, Q) \) between \( \ell(P_1) \) and \( \ell(Q) \) is equal to the operator \( \hat{\mathcal{R}}_1 \) of multiplication by a matrix-valued function \( e^{\theta_1(x) J + \theta_2(x) I} \), where \( \theta_1 \) and \( \theta_2 \) are given as in (4.3), but with \( P \) replaced by \( P_1 \). Since \( \theta_1 \equiv 0 \) for Hermitian \( P_1 \) and \( Q \) with real entries, we conclude that \( P_1 = P \) by step 1, thus completing the proof of theorem 5.2.

Theorem 5.2 implies that there is a unique \( P \in \mathcal{P} \) such that \( \mathbf{sd}(P) = \mathbf{sd}^* \), for every augmentation \( \mathbf{sd}^* \) of the set \( \mathbf{sd} \). As explained at the beginning of this section, the Dirac operator \( \hat{\mathcal{R}}(P) \) with every such \( P \) yields a pencil \( T_{p,q} \) with spectral data \( \mathbf{sd} \), thus establishing theorem 2.7.

However, as the augmented set \( \mathbf{sd}^* \) depends on the arbitrary choice of \( a_0 > 0 \), different \( a_0 \) lead to different \( P \in \mathcal{P} \), and, plausibly, to different quadratic operator pencils \( T_{p,q} \). This uniqueness issue is discussed in detail in the following section.
6. Reconstruction of the pencil: uniqueness

In this section, we prove theorem 2.5 and thus complete the study of the inverse spectral problem for quadratic pencils $P_{p,q}$. Namely, we show that the matrix potentials $P \in \mathcal{P}$ constructed in the previous section lead to the same $p$ and $q$ for all choices of the positive parameter $\alpha_0$.

We again start with an arbitrary element $s = \ell(\alpha_0) \in SD$, set $\lambda_0 := 0$, choose an arbitrary positive number $\alpha_0$ and augment $s$ with the pair $(\lambda_0, \alpha_0)$. Then we construct a shifted AKNS potential $Q \in \mathcal{Q}_0$ and the corresponding potential $P \in Iso(Q) \cap \mathcal{P}$ whose spectral data coincide with the augmented set, see proposition 5.1 and theorem 5.2.

Choose now a positive number $\tilde{\alpha}_0$ different from $\alpha_0$. Augmenting the set $s$ with $(\lambda_0, \tilde{\alpha}_0)$, we obtain spectral data for another Dirac operator $D(Q)$ with potential $\tilde{Q} \in \mathcal{Q}_0$, and construct the corresponding potential $P \in Iso(\tilde{Q}) \cap \mathcal{P}$.

It turns out that the potentials $Q$ and $\tilde{Q}$ are related via the so-called double commutation transformations, see details in [54, section 3] and [6].

**Proposition 6.1.** Suppose that two potentials $Q$ and $\tilde{Q}$ from $\mathcal{Q}_0$ are as described above, i.e. the spectra of the corresponding Dirac operators $D(Q)$ and $D(\tilde{Q})$ coincide and the norming constants $\alpha_n$ and $\tilde{\alpha}_n$ only differ for $n = 0$. Then

$$\tilde{Q} = Q + Q_*, \quad (6.1)$$

where

$$Q_* = c(x, \alpha_*)[v(x)v^*(x)J - Jv(x)v^*(x)], \quad (6.2)$$

$$c(x, \alpha_*) := \frac{\alpha_*}{1 + \alpha_* \int_0^{\infty} v(s)v(s)ds}, \quad \alpha_* := \frac{1}{\alpha_0} - \frac{1}{\alpha_0} \quad (6.3)$$

and $v$ is an eigenfunction of the operator $D(Q)$ corresponding to the eigenvalue $\lambda = 0$.

Recalling the way the operators $D(Q)$ and $D(P)$ are related and remark 3.3 on the form of the eigenvector $u$ of $D(P)$ corresponding to the eigenvalue $\lambda = 0$, we can write a more explicit formula for $Q_*$. Indeed, by theorem 4.5 the transformation operator $D'(P, Q)$ for the Dirac differential expressions $\ell(P)$ and $\ell(Q)$ on the set $D_0$ is just the operator $D$ of multiplication by the matrix-valued function $R = e^{i\theta J}$, with $\theta$ being the solution of (5.4) satisfying $\theta(0) = 0$. Therefore, $v = D'u = e^{i\theta J}u$; as $u = (u_1, 0)^T$ and $(e^{i\theta J})' = e^{-i\theta J}$, we easily compute that $v^Tv = u^Tu = u_1^2$ and

$$uu'J - Juu' = u_1^2J_1,$$

with

$$J_1 := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

Observing that the matrices $J$ and $J_1$ anticommute, we conclude that $e^{i\theta J}J_1 = J_1 e^{-i\theta J}$; henceforth,

$$v^TvJ - Jv^Tv = e^{i\theta J}[uu'J - Juu']e^{-i\theta J} = u_1^2 e^{i\theta J}J_1 e^{-i\theta J} = u_1^2 e^{2i\theta J}J_1.$$

Set $w(x) := 1 + \alpha_\lambda \int_0^x v^2(s)\,ds$; then $c(x, \alpha_\lambda)u_1^2(x) = -w'(x)/w(x) = -[\log w(x)]'$, thus resulting in the following form of the potential $Q_*$. 

Corollary 6.2. For the potentials $Q$ and $\tilde{Q}$ of proposition 6.1, relation (6.1) holds with
\[
Q_+(x) = -\left[\log w(x)\right]' e^{\theta_2(x)} J_1 = -\left[\log w(x)\right]' \begin{pmatrix} \sin 2\theta_2(x) & \cos 2\theta_2(x) \\ \cos 2\theta_2(x) & -\sin 2\theta_2(x) \end{pmatrix}, \tag{6.4}
\]
where $\theta_2$ is the solution of (5.4) satisfying $\theta(0) = 0$, $u_1$ is the first component of the eigenvector $u$ of $\mathcal{D}(P)$ corresponding to the eigenvalue $\lambda_0 = 0$ and
\[
w(x) = 1 + \alpha_s \int_0^x u_1^2(s) \, ds. \tag{6.5}
\]

Now we use the explicit formulae (5.3) and (5.4) determining the potential $P$ from $Q$ and the analogous formula for $\tilde{P}$ and $\tilde{Q}$ to derive the crucial result relating $P$ and $\tilde{P}$.

Lemma 6.3. For the entries $p_{ij}$ and $\tilde{p}_{ij}$ of the matrices $P$ and $\tilde{P}$ constructed above, the following relations hold:
\[
\tilde{p}_{22} = p_{22}, \quad \tilde{p}_{12} = p_{12} - (\log w)',
\]
with the function $w$ of (6.5).

Proof. First we recall that $\theta_2$ is the unique solution of equation (5.4),
\[-\theta' + q_1 \cos 2\theta - q_2 \sin 2\theta + h = 0,
\]
satisfying the initial condition $\theta(0) = 0$; here $q_1$ and $q_2$ are the entries of the AKNS part $Q_0$ of the potential $Q$ as in (5.2). Likewise, $\tilde{\theta}_2$ is the unique solution of
\[-\tilde{\theta}' + \tilde{q}_1 \cos 2\tilde{\theta} - \tilde{q}_2 \sin 2\tilde{\theta} + h = 0
\]
satisfying $\tilde{\theta}(0) = 0$, with $\tilde{q}_1$ and $\tilde{q}_2$ having similar meaning. Equality (6.4) together with proposition 6.1 allows to recast the latter equation for $\tilde{\theta}_2$ as
\[-\tilde{\theta}' + q_1 \cos 2\tilde{\theta} - q_2 \sin 2\tilde{\theta} + h + (\log w)' \sin(2\tilde{\theta} - 2\theta_2) = 0.
\]
Observe that $\tilde{\theta} \equiv \theta_2$ is a solution of this equation satisfying the initial condition $\tilde{\theta}(0) = 0$; therefore, uniqueness of solutions yields $\tilde{\theta}_2 = \theta_2$.

The potential $\tilde{P}$ is related to $\tilde{Q} = Q + Q_+$ through a formula analogous to (5.3), i.e.
\[
\tilde{P} = \tilde{R}^{-1} J \tilde{R} + \tilde{R}^{-1} (Q + Q_+) \tilde{R},
\]
with $\tilde{R} = e^{\tilde{\theta} J} = e^{\theta J} = R$. Therefore, we find that
\[
\tilde{P} - P = R^{-1} Q_+ R = e^{-\theta J} \left[ - (\log w)' e^{\theta J} J_1 e^{-\theta J} \right] = - (\log w)' J_1.
\]
As a result, $\tilde{p}_{22} = p_{22}$ and $\tilde{p}_{12} = p_{12} - (\log w)'$, and the lemma is proved.

Corollary 6.4. The potentials $P$ and $\tilde{P}$ constructed above generate the same operator pencil $T_{p,q}$.

Proof. In view of (5.1) and the above lemma it remains to show that
\[-\tilde{p}_{12}^2 + \tilde{p}_{12} = -p_{12}^2 + p_{12}^2.
\]
By remark 3.3, we have $u_1(x) = \int_0^x p_{12}(s) \, ds$, so that $u_1' = p_{12} u_1$. Since $w' = \alpha_s u_1^2$, $w'' = 2\alpha_s u_1' u_1 = 2p_{12} w'$ and
\[
(\log w)' = \frac{w''}{w} - \left( \frac{w'}{w} \right)^2 = 2p_{12} (\log w)' - [(\log w)']^2,
\]

upon substituting $\hat{p}_{12} = p_{12} - (\log w)'$, we find that
\[-\hat{p}_{12}^2 + \hat{p}_{12}^2 = -\hat{p}_{12}' + (\log w)' + p_{12}' - 2p_{12}(\log w)' + [(\log w)]^2 = -\hat{p}_{12}' + \hat{p}_{12}^2\]
as claimed. The proof is complete. □

**Proof of theorem 2.5.** Suppose there are two pencils, $T = T_{p,q}$ and $\hat{T} = T_{\hat{p},\hat{q}}$, satisfying assumption (A) and having the same spectral data in SD. As explained in section 3, these pencils lead to two Dirac operators $\mathcal{D}(P)$ and $\mathcal{D}(\hat{P})$ with some potentials $P$ and $\hat{P}$ in $\mathcal{P}$.

The spectral data for $\mathcal{D}(P)$ and $\mathcal{D}(\hat{P})$ can only differ at the norming constant for the eigenvalue $\lambda = 0$; denote these norming constants by $\alpha_0$ and $\hat{\alpha}_0$, respectively.

Now take $\hat{\alpha}_0 = \hat{\alpha}_0$ and construct the potential $\hat{P} \in \mathcal{P}$ as explained at the beginning of this section. By corollary 6.4, $P$ and $\hat{P}$ generate the same pencil $T$. On the other hand, the potentials $\hat{P}$ and $P$ are isospectral and belong to $\mathcal{P}$ and thus coincide by theorem 5.2. Therefore, $T$ and $\hat{T}$ coincide as well, and the proof is complete. □

### 7. Reconstruction algorithm and some extensions

The proof of existence theorem (theorem 2.7) contains explicit steps forming the reconstruction algorithm. Namely, given an arbitrary element $sd$ of SD, we construct a quadratic pencil $T_{p,q}$—i.e. the Sturm–Liouville eigenvalue problem (1.1) with potentials $p \in L_{2,\mathbb{R}}(0, 1)$ and $q \in W^{-1}_{2,\mathbb{R}}(0, 1)$—in the following way:

1. fix the enumeration $(\lambda_n, \alpha_n), n \in \mathbb{Z}^*$, of the pairs $(\lambda, \alpha)$ in $sd$ so that $\lambda_n$ increase, $\lambda_{-1} < 0$, $\lambda_1 > 0$, and determine the shift $h$ from the asymptotic representation of $\lambda_n$;
2. augment the set $sd$ with a pair $(\lambda_0, \alpha_0)$, where $\lambda_0 = 0$ and $\alpha_0$ is an arbitrary positive number;
3. construct a Dirac operator $\mathcal{D}(Q)$ with potential $Q$ in the shifted AKNS class $Q_\alpha$ whose spectral data coincide with the augmented set $sd^*$ (see proposition 5.1);
4. find the corresponding potential $P \in \mathcal{P} \cap \text{Iso}(Q)$ via (5.3) and (5.4);
5. compute the potentials $p$ and $q$ using formulas (5.1).

We finish the paper with several comments. Firstly, the above algorithm can be used to reconstruct the potentials $p$ and $q$ under different assumptions on their regularity. Namely, if $p$ and a primitive $r$ of $q$ belong to $L_s(0, 1)$ with $s \geq 1$, then the corresponding set SD of spectral data allows an explicit description (the only difference with the $s = 2$ case is in the decay of the remainders $\hat{\lambda}_n$ and $\hat{\alpha}_n$) and the steps of reconstruction are as above; cf the characterization of the spectral data for the corresponding class of Dirac operators in [5]. Similar characterization of the set SD is available if $p$ and $r$ belong to $W^1_s(0, 1)$ with $s \geq 2$; cf the results of [21, 52] on eigenvalue asymptotics for Sturm–Liouville operators with potentials in Sobolev spaces.

Secondly, the approach described is not restricted to the Dirichlet boundary conditions and can be used to reconstruct energy-dependent Sturm–Liouville equations under quite general separated boundary conditions.

Finally, reconstruction from different sets of spectral data (e.g., from two spectra, or from Hochstadt–Lieberman mixed data) using this method is also possible and will be considered elsewhere, cf [45]. One can also get Hochstadt-type results [18] on the explicit form of the potentials when only finitely many spectral data are changed.
