Abstract

A complete $k$-coloring of a graph $G = (V, E)$ is an assignment $\varphi : V \to \{1, \ldots, k\}$ of colors to the vertices such that no two vertices of the same color are adjacent, and the union of any two color classes contains at least one edge. Three extensively investigated graph invariants related to complete colorings are the minimum and maximum number of colors in a complete coloring (chromatic number $\chi(G)$ and achromatic number $\psi(G)$, respectively), and the Grundy number $\Gamma(G)$ defined as the largest $k$ admitting a complete coloring $\varphi$ with exactly

colors such that every vertex $v \in V$ of color $\varphi(v)$ has a neighbor of color $i$ for all $1 \leq i < \varphi(v)$. The inequality chain $\chi(G) \leq \Gamma(G) \leq \psi(G)$ obviously holds for all graphs $G$. A triple $(f,g,h)$ of positive integers at least 2 is called realizable if there exists a connected graph $G$ with $\chi(G) = f$, $\Gamma(G) = g$, and $\psi(G) = h$. In [8], the list of realizable triples has been found. In this paper we determine the minimum number of vertices in a connected graph with chromatic number $f$, Grundy number $g$, and achromatic number $h$, for all realizable triples $(f,g,h)$ of integers. Furthermore, for $f = g = 3$ we describe the (two) extremal graphs for each $h \geq 6$. For $h = 4$ and 5, there are more extremal graphs, their description is contained as well.

1 Introduction

A complete coloring of a graph is an assignment of colors to the vertices in such a way that adjacent vertices receive different colors, and there is at least one edge between any two color classes. In other words, the coloring is proper and the number of colors cannot be decreased by identifying two colors.

Let $G = (V,E)$ be any simple undirected graph. The minimum number of colors in a proper coloring is the chromatic number $\chi(G)$, and all proper $\chi$-colorings are necessarily complete. The maximum number of colors in a complete coloring is the achromatic number $\psi(G)$. Every graph admits a complete coloring with exactly $k$ colors for all $\chi \leq k \leq \psi$ (Harary et al., [15]). An important variant of complete coloring, called Grundy coloring or Grundy numbering, requires a proper coloring $\varphi : V \to \{1, \ldots, k\}$ such that every vertex $v \in V$ has a neighbor of color $i$ for each $1 \leq i < \varphi(v)$. The largest integer $k$ for which there exists a Grundy coloring of $G$ is denoted by $\Gamma(G)$ and is called the Grundy number of $G$. Certainly, $\Gamma(G)$ is sandwiched between $\chi(G)$ and $\psi(G)$. One should emphasize that $\chi(G)$ and $\psi(G)$ are defined in terms of unordered colorings, i.e., permutation of colors does not change the required property of a coloring. On the other hand, in a Grundy coloring the order of colors is substantial.

Proper colorings have found a huge amount of applications and hence, besides their high importance in graph theory, they are very well motivated from the practical side, too. The chromatic number occurs in lots of optimization problems. The achromatic number looks less practically motivated, nevertheless it expresses the worst case of a coloring algorithm which creates a proper color partition of a graph in an arbitrary way and then applies the improvement heuristic of identifying two colors as long as no monochromatic edge is created. Grundy colorings have strong motivation from game theory; moreover, $\Gamma(G)$ describes the worst case of First-Fit coloring algorithm when applied to a graph $G$ if we do not know the graph in advance, the vertices arrive one by
one, and we irrevocably assign the smallest feasible color to each new vertex as a best local choice. Then the number of colors required for a worst input order is exactly \( \Gamma(G) \). For this reason, \( \Gamma(G) \) is also called the \textit{on-line First-Fit chromatic number} of \( G \) in the literature.

An overview of on-line colorings and a detailed analysis of the First-Fit version is given in [4]. A more extensive survey on the subject can be found in [19]. The performance of First-Fit is much better on the average than in the worst case. This is a good reason that it has numerous successful applications. This nicely shows from a practical point of view that the Grundy number is worth investigating.

The definition of Grundy number is usually attributed to Christen and Selkow [10], although its roots date back to the works of Grundy [12] four decades earlier; and in fact \( \Gamma(G) \) of an undirected graph \( G \) is equal to that of the digraph in which each edge of \( G \) is replaced with two oppositely oriented arcs. In general, computing the Grundy number is \( \text{NP} \)-hard, and it remains so even when restricted to some very particular graph classes, e.g., to bipartite graphs or complements of bipartite graphs ([16] and [26], respectively). Actually, the situation is even worse: there does not exist any polynomial-time approximation scheme to estimate \( \Gamma(G) \) unless \( P = \text{NP} \) [20], and for every integer \( c \) it is \text{coNP}-complete to decide whether \( \Gamma(G) \leq c \chi(G) \), and also whether \( \Gamma(G) \leq c \omega(G) \), where \( \omega(G) \) denotes the clique number of \( G \) (see [1]). Several bounds on \( \Gamma(G) \) in terms of other graph invariants were given, e.g., in [5, 24, 28]. On the other hand, by the finite basis theorem of Gyárfás et al. [13] the problem of deciding whether \( \Gamma(G) \geq k \) can be solved in polynomial time, when \( k \) is a fixed integer (see also [6] for results on Grundy critical graphs). Moreover, there are known efficient algorithms to determine the Grundy number of trees [17] and more generally of partial \( k \)-trees [24].

Concerning the achromatic number, on the positive side there exists a constant-approximation for trees [9] and a polynomial-time exact algorithm for complements of trees [25]. But in a sense, the computation of \( \psi(G) \) is harder than that of \( \Gamma(G) \). It is \text{NP}-complete to determine \( \psi(G) \) on connected graphs that are simultaneously interval graphs and co-graphs [3], and even on trees [7, 23]. Moreover, no randomized polynomial-time algorithm can generate with high probability a complete coloring with \( C \psi(G) / \sqrt{n} \) colors for arbitrarily large constant \( C \), unless \( \text{NP} \subseteq \text{RTIME}(n^{\text{poly log } n}) \), and under the same assumption \( \psi(G) \) cannot be approximated deterministically within a multiplicative \( \lg^{1/4-\varepsilon} n \), for any \( \varepsilon > 0 \) [22], although some \( o(n) \)-approximations are known [3, 21].

The strong negative results above concerning algorithmic complexity also mean a natural limitation on structural dependencies, for all the three graph invariants \( \chi, \Gamma, \psi \). On the other hand, quantitatively, the triple \((\chi, \Gamma, \psi)\) can take any non-decreasing sequence of integers at least 2. (The analogous assertion for \((\chi, \psi)\) without \( \Gamma \) appeared in [22].) For example, if \( \chi = \Gamma = 2 \), then properly choosing the size of a union of complete graphs on two vertices will do for any given \( \psi \). Assuming connectivity, however, makes a difference. Let us call a triple \((f, g, h)\) of integers with \( 2 \leq f \leq g \leq h \) \textit{realizable} if there exists a connected graph \( G \) such that \( \chi(G) = f \), \( \Gamma(G) = g \), and \( \psi(G) = h \). It was
proved by Chartrand et al. [8] that a triple is realizable if and only if either $g \geq 3$ or $f = g = h = 2$.

Here we address the naturally arising question of smallest connected graphs with the given coloring parameters. Namely, for a realizable triple $(f, g, h)$, let us denote by $n(f, g, h)$ the minimum order of a connected graph $G$ with $\chi(G) = f$, $\Gamma(G) = g$ and $\psi(G) = h$. The lower bound $n(f, g, h) \geq 2h - f$ was proved in [8, Theorem 2.10] in the stronger form $2\psi - \omega$ (where $\omega$ denotes clique number), and this estimate was also shown to be tight for $g = h$. On the other hand the order of graphs constructed there to verify that the triple $(f, g, h)$ is realizable was rather large, and had a high growth rate. In particular, for every fixed $f$ and $g$, the number of vertices in the graphs of [8] realizing $(f, g, h)$ grows with $h^2$ as $h$ gets large, while the lower bound is linear in $h$.

For instance, the construction for $f = g$, described in [18], takes the complete graph $K_f$ together with a pendant path $P_k$, having properly chosen number of vertices $k$, and applies the facts that very long paths make $\psi$ arbitrarily large and that the removal of the endvertex of a path (or actually any vertex of any graph) decreases $\psi$ by at most 1, as proved in [11].

In this paper we determine the exact value of $n(f, g, h)$ for every realizable triple $(f, g, h)$, showing that the lower bound $2h - f$ is either tight or just one below optimum.

It is easy to see that the complete graph $K_f$ verifies $n(f, f, f) = f$ for all $f \geq 2$. For the other cases it will turn out that the formula depends on whether $f < g$. These facts are summarized in the following two theorems; the case $g = h$ was already discussed in [8].

**Theorem 1** For $2 \leq f < g$ and for $f = g = h$, $n(f, g, h) = 2h - f$.

**Theorem 2** For $2 < f = g < h$, $n(f, g, h) = 2h - f + 1$.

**Remark 1** As one can see, the minimum does not depend on $g$, apart from the distinction between $f = g$ and $f < g$.

The two theorems above will be proved in the following two sections, while in the last section for each $h > 3$ we determine the number of extremal graphs (the graphs of minimum order) that realize the triple $(3, 3, h)$.

**Theorem 3** Let $f = g = 3$. If $h = 4$, then there are seven extremal graphs. If $h = 5$, then there are three such graphs, while for every $h \geq 6$ there are exactly two of them.

Along the proof of Theorem 3 we will also determine the structure of all extremal graphs.

In what follows we need some additional terms and notation. Given a graph $G = (V, E)$ and a vertex set $X \subseteq V$, the subgraph induced by $X$ will be denoted by $G[X]$. A set of vertices $X$ is dominated by another one, say $D$, if every $x \in X \setminus D$ has at least one neighbor in $D$. A set $D$ is dominating if it dominates the whole vertex set. We will also say that a set $D$ dominates a subgraph $H$ in the sense that $D$ dominates $V(H)$. A set $S$ is said to be stable if it does not contain any pair of adjacent vertices.
2 The case $\chi < \Gamma$ — Proof of Theorem 1

First, we consider the lower bound for $n(f, g, h)$. From [8, Theorem 2.10], it follows that for all $f, g, h$ satisfying conditions of Theorem 1 it holds that $n(f, g, h) \geq 2h - f$. The idea is that $h$ color classes on fewer than $2h - f$ vertices would yield at least $f + 1$ singleton classes, but then they should be mutually adjacent if the coloring is complete. This leads to the contradiction $f + 1 \leq \omega(G) \leq \chi(G)$.

Considering the tightness of the bound we construct an appropriate bipartite graph to prove the following lemma

Lemma 1 The lower bound $2h - f$ is tight for the case $f = 2$.

Construction I

For every $k \geq 2$ we define a basic bipartite graph $B_k$, with vertex set $X = U \cup W$, where $U = \{u_1, u_2, \ldots, u_{k-1}\}$ and $W = \{w_2, w_3, \ldots, w_k\}$, and edge set

$$C = \{u_iw_j \mid 1 \leq i < j \leq k\}.$$

We call $U$ and $W$ the partite sets of $B_k$. See Figure 1 for the graph $B_7$ that will be used several times.

![Figure 1: Graph $B_7$](image)

For $g = 3$, we consider $B_h$ itself. However, for $g \geq 4$, we denote $\gamma = g - 3$, and modify the graph $B_h$ by inserting the following set of edges:

$$\{u_iw_j \mid 1 \leq i - j \leq \gamma, \ 2 \leq i \leq h - 1, \ 2 \leq j \leq h - 2\}.$$

We shall call them the inserted edges.

For any $g \geq 3$, the graph with inserted edges will be denoted by $G(2, g, h)$, and in the following text, briefly by $G^*$. We show an example of $G^*$ in Figure 2.
Proposition 1 \( \chi(G^*) = 2 \), \( \Gamma(G^*) = g \), and \( \psi(G^*) = h \).

Proof By definition, \( G^* \) is bipartite, i.e., \( \chi(G^*) = 2 \) and the color classes \( \{u_1\}, \{u_2, w_2\}, \ldots, \{u_{h-1}, w_{h-1}\}, \{w_h\} \) verify that \( \psi(G^*) \geq h \) is valid, whereas \( \psi(G^*) \leq h \) also holds because \( G^* \) has no more than \( 2h - 2 \) vertices. Hence, what remains to prove is that \( \Gamma(G^*) = g \).

For \( g < h \), the proof of the lower bound \( \Gamma(G^*) \geq g \) is obtained by assigning color \( g \) to \( u_1 \), color \( i - 1 \) to \( \{u_i, w_i\} \) for \( i = 2, \ldots, g - 1 \), color 1 again to \( u_g, \ldots, u_{h-1} \), and finally color \( g - 1 \) to \( w_j \) for \( j = g, \ldots, h \). Consequently, \( \Gamma(G^*) \geq g \).

For \( g = h \), the only difference is that in the set \( U \), color 1 is assigned to exactly one vertex, namely to \( u_2 \).

To prove the upper bound on \( \Gamma(G^*) \) is more difficult. We manage it as a separate statement.

Claim 1 \( \Gamma(G^*) \leq g \)

Throughout the argumentation, we assume that \( \Gamma(G^*) > g \). Claim 4 will be a consequence of Claim 3 below. Before proving those claims we need some additional notation and a simple Claim 2.

Let us call a stable set \( S \) a double set if it meets both partite sets. Considering a Grundy coloring of \( G^* \) with \( \Gamma(G^*) \) colors, a double class is a color class which is a double set. Graph \( G^* \) is bipartite and there must be an edge between any two color classes. Moreover, the classes containing \( u_1, w_h \) respectively, are non-double. Thus, the number of non-double classes is exactly 2. We denote the double classes by \( D_1, D_2, \ldots, D_\Delta \), indexed with their colors; here \( \Delta = \Gamma(G^*) - 2 \).

Let \( S \) be any double set, let \( I = I(S) \) be the minimum of \( \{i \mid u_i \in S\} \) and let \( J = J(S) \) be the maximum of \( \{j \mid w_j \in S\} \). For \( S = D_k \) we denote \( I(S) \) also by \( I_k \) and similarly \( J_k \) for \( J(S) \).

The following claim is straightforward, so the proof is omitted.
Claim 2  \( I(S) \geq J(S) \) for any double set \( S \) and, in particular, for any double class. \( \square \)

We shall use the term reduced graph and notation \( R_t \) for the bipartite graph \( K_{t,t} - tK_2 \) obtained from the complete bipartite graph \( K_{t,t} \) by omitting a 1-factor. (This graph was taken in [8] for \( f = 2 \) and \( g = h > 2 \).) The essence of the proof is given in the following claim. Let us recall that \( \Delta \) is the number of double classes.

Claim 3

(i) The subgraph \( H \) induced by the vertex set

\[ \{ u_I \mid I = I(D), \ D \text{ is a double class} \} \cup \{ w_J \mid J = J(D), \ D \text{ is a double class} \} \]

is isomorphic to \( R_\Delta \).

(ii) The graph \( G^* \) does not contain any induced subgraph isomorphic to \( R_\Theta \) with \( \Theta \geq \gamma + 2 \).

Proof We start with an observation that nothing has been stated concerning the position of \( \{ I_k, J_k \} \) in the “omitted 1-factor”.

In order to prove (i) we take two arbitrary double classes \( D_k \) and \( D_K \) with \( k < K \) and consider the vertices \( u_i, u_I, w_J, w_J \) where \( i = I_k, \ I = I_K, \ j = J_k, \ J = J_K \). We will prove that \( u_Iw_J \in E(G^*) \) and \( u_iw_J \in E(G^*) \), this will yield the assertion since \( \{ I_k, J_k \mid 1 \leq k \leq \Delta \} \) will play the role of the “omitted 1-factor”.

Let us consider the first statement. Suppose for a contradiction that \( u_Iw_J \notin E(G^*) \). From the properties of Grundy coloring, \( u_I \) has some neighbor \( w_\lambda \) in \( D_k \). By the maximality of \( j, j \geq \lambda \) holds and \( w_J \) is adjacent to \( u_I \) for every \( I \neq j \). We may suppose the latter case since otherwise the proof is done. Similarly, we obtain that \( w_J \) has a neighbor \( u_\mu \) in \( D_k \).

Since all of \( w_{j-\gamma}, w_{j-\gamma+1}, \ldots, w_h \) except \( w_J \) are adjacent to \( u_I \), the non-edge \( u_Iw_J \) implies \( J < I - \gamma \), and \( i \leq \mu \) also holds. Hence, the following chain of inequalities is valid:

\[ J < I - \gamma = j - \gamma \leq i - \gamma \leq \mu - \gamma. \]

Consequently, the vertices \( u_I \) and \( w_J \) are adjacent, as claimed.

By the central symmetry of \( G^* \), the relation \( u_Iw_J \in E(G^*) \) is established in the same way.

In order to prove (ii) suppose that \( G^* \) has an induced subgraph \( R \) isomorphic to \( R_\Delta \) with \( \Delta \geq \gamma + 2 \). Let \( Z \) be the vertex set of \( R \). If \( u \in Z \cap U, \ w \in Z \cap W \), and \( uw \notin E(G^*) \), then we call \( w \) the match of \( u \) and vice versa. Let us denote by \( a = u_M \) the vertex of largest subscript in \( Z \cap U \) and by \( b = w_m \) the vertex of smallest subscript in \( Z \cap W \).
First, suppose \( ab \in E(G^*) \). In case \( M < m \), the graph \( R \) would be a complete bipartite graph. So \( M \leq m + \gamma \). Let us take any vertex \( u_i \) in \( (Z \cap U) \ \{ a \} \). We observe that \( m \leq i < M \). Indeed, the second inequality is trivial; and if the first one was not true then \( u_i \) would have no match. This means that all the subscripts of the vertices in \( Z \cap U \) are in the interval \([m, M] \subseteq [m, m + \gamma] \) and thus \( \Delta \leq \gamma + 1 \), proving the assertion if \( ab \in E(G^*) \).

Second, suppose \( ab \notin E(G^*) \). Then the match of \( a = u_M \) is \( b = w_m \). Surely, for every vertex \( u_i \) in \( Z \cap U \) with \( i \neq M \), we have \( i \leq m + \gamma \) because \( u_i w_m \in E(G^*) \), and \( m < i \), for otherwise \( u_i \) would have no match. Consequently, \( \Delta \leq \gamma + 1 \).

Thus we have proved Claim 3.

As a consequence of the above claim, \( \Delta \leq \gamma + 1 = g - 2 \) and \( \Gamma(G^*) \leq g \) follow. Thus Claim 1 is established; moreover Proposition 1 and Lemma 1 are proved.

Note that we have also proved Theorem 1 for \( f = 2 \). It has been observed in [8, Proposition 2.8] that if we take the join of the current graph with a new vertex, then each of \( \chi, \Gamma, \psi \) increases by exactly 1. Thus, for a given triple \((f, g, h)\) with \( f \geq 3 \) we can start from \( G(2, g', h') \), where

\[
g' = g - f + 2, \quad h' = h - f + 2
\]

and join it with \( K_{f-2} \). In this way we obtain a connected graph that realizes \((f, g, h)\) and has exactly \((2h' - 2) + (f - 2) = 2h - f \) vertices. This completes the proof of Theorem 1.

3 The case \( \chi = \Gamma \) — Proof of Theorem 2

Similarly as above, we shall give the proof in two parts. Before proving the lower bound, we show an auxiliary statement which will be applied many times.

Claim 4 Given a graph \( G \), suppose there exists an induced subgraph \( H \) of \( G \), with \( \Gamma(H) \geq k \) and a stable set, disjoint from \( V(H) \) and dominating \( H \). Then the Grundy number of \( G \) is strictly larger than \( k \).

Proof For both \( G \) and \( H \), the stable set can get color 1, and the vertices of \( H \) can be colored with numbers one larger than in the original Grundy numbering of \( H \). This induces a subgraph of Grundy number larger than \( k \), and we can use the fact that \( \Gamma \) is monotone with respect to taking induced subgraphs.

Remark 2 In most of the applications, \( H \) will be a \( K_3 \) or a \( P_4 \) and \( k \) will be 3. As another special case, we shall often find a maximal stable set of \( G \), disjoint from some subgraph \( H \) of \( G \).

Now we are in a position to establish the first part of the theorem.
Lemma 2  If $2 < f = g < h$, then $n(f,g,h) \geq 2h - f + 1$.

Proof  Suppose for a contradiction that there exists a graph $G$ with the given coloring parameters on $n < 2h - f + 1$ vertices. By what has been said at the beginning of Section 2, this implies $n = 2h - f$. From the argument sketched there we also see that the conditions $n = 2h - f$ and $\psi(G) = h > f$ imply that in any complete $h$-coloring of $G$ there exist $f$ singleton color classes, say $S_1 = \{y_1\}, S_2 = \{y_2\}, \ldots, S_f = \{y_f\}$, inducing a complete subgraph in $G$. Moreover, by the condition $h > f$, there is at least one further color class, say $S_{f+1}$.

Since the coloring is assumed to be complete, each $y_i (1 \leq i \leq f)$ is adjacent to at least one vertex of $S_{f+1}$. Hence, by Claim 4 we obtain $\Gamma(G) > f = g$, a contradiction.

Lemma 2 is established. 

The proof of the following lemma, which establishes the second part of the theorem, will be split into several claims.

Lemma 3  If $2 < f = g < h$, then $n(f,g,h) \leq 2h - f + 1$.

Proof  Two graphs will be constructed with the appropriate number of vertices, for $f = g = 3$. This will be enough since the simple extension adjoining $K_h - f + 3$ will work like earlier (see end of the proof of Theorem 1).

First, we recall the simple fact from the proof of [8, Proposition 2.5] that a connected graph $G$ has $\Gamma(G) = 2$ if and only if $G$ is a complete bipartite graph. This can be extended also to disconnected graphs:

Claim 5  For a graph $G$, $\Gamma(G) \leq 2$ is equivalent to the following property:

(I) Each component of $G$ is either an isolated vertex or a complete bipartite graph. 

Note that under the present conditions we have $h \geq 4$. Starting from the basic bipartite graph $B_{h-2}$ introduced in the previous section, we are going to construct two graphs $L_1$ and $L_2$ with larger parameters by inserting vertices and edges, different from Construction I.

Construction II

Let $\ell = h - 2$ and consider the bipartite graph $B_\ell = (X,C)$ of Section 2. First, we extend $B_\ell$ with two isolated vertices $u_\ell$ and $w_1$ to obtain the extended graph $B'_\ell$. We also introduce the notation $U' = \{u_1, \ldots, u_\ell\}, W' = \{w_1, \ldots, w_\ell\}$. Let $L_i = (Y, D_i)$, $i \in \{1, 2\}$ be the graph with the vertex set $Y = U' \cup W' \cup \{q_1, q_2\}$, and the edge set $D_1 = D_0 \cup \{q_2u_\ell, q_1w_1, q_1q_2\}$ or $D_2 = D_0 \cup \{q_2u_\ell, q_1q_2\}$, respectively, where $D_0 = C \cup \{q_1u \mid u \in U'\} \cup \{q_2w \mid w \in W'\}$. 

In Figure 3 we present an example of $L_1$ and $L_2$, when $\ell = 7$ (white vertices induce $B_\ell$). From now on, we shall also refer to both graphs shortly as $L$.

The following claim contains an easier part of the proof of Lemma 3. Later we shall deal with a more difficult one.
Claim 6

(i) $\chi(L) = 3$,
(ii) $\psi(L) = h$.

Proof

(i) The graph $L$ contains a triangle, and we can easily find a coloring with three colors, shown in Figure 4.

(ii) The vertex partition of $L$ into the $h$ stable sets $\{q_1\}, \{q_2\},$ and $\{u_i, w_i\}$, $i \in \{1, \ldots, \ell\}$ is a complete coloring with exactly $h > 3$ colors. Thus, $\psi(L) \geq h$. Conversely, the upper bound $h$ for $\psi(L)$ comes from the arguments used in the proof of Lemma 2. The fact that $|V(L)| = 2h - 2$ is also important but it follows easily from the construction. \hfill $\blacksquare$

We continue with the harder part of the lemma. First we state a property similar to that of Claim 2.

Claim 7 The maximal stable sets $S$ of graph $B'_h$ are of the following form:

$$S = S_N = \{w_1, \ldots, w_N\} \cup \{u_{N+1}, \ldots, u_\ell\}$$

for some $1 \leq N \leq \ell$. \hfill $\blacksquare$

We note that the extremal cases $N = 1$ and $N = \ell$ correspond to $U' \cup \{w_1\}$ and $W' \cup \{u_\ell\}$, respectively. Moreover $\{u_\ell, w_1\}$ is contained in all $S$, hence every $S$ meets both $U'$ and $W'$.

Concerning stable sets of the graph $L$, we have the following:

Claim 8 For any maximal stable set $S$ of $L$, the induced subgraph $L - S$ has property (II) stated in Claim 2.
Figure 4: Proper 3-coloring of $L_1$

Proof Take an arbitrary $S$. There are three cases:

(a) $S \subseteq V(B'_h)$,
(b) $q_1 \in S$,
(c) $q_2 \in S$.

In the first case, $S$ is a maximal stable set of the graph $B'_h$, and by Claim 7 we have $S = S_N$ for some $1 \leq N \leq \ell$. The complement of $S$ with respect to the vertex set of $L$ is the set $\{u_1, ..., u_{N-1}\} \cup \{w_{N+1}, ..., w_\ell\} \cup \{q_1, q_2\}$ and induces a complete bipartite graph with vertex classes $\{u_1, ..., u_{N-1}\} \cup \{q_2\}$ and $\{w_{N+1}, ..., w_\ell\} \cup \{q_1\}$ since $u_\ell \in S$ necessarily holds. This verifies property (II).

In the second case, $S \subseteq W' \cup \{q_1\}$ and, in fact, $S$ is equal to this set, because of maximality. The complement of $S$ with respect to the vertex set of $L$, namely $U' \cup \{q_2\}$, induces a subgraph consisting of $U$ (see Construction I to recall the definition) as $\ell - 1$ isolated vertices, together with the isolated edge $u_\ell q_2$. So it does have property (II).

The third case is similar and yields that $L - S$ is induced by the stable set $W$ plus the isolated edge $u_\ell q_1$. $\square$

Finally, we prove

Claim 9 $\Gamma(L) = 3$.

Proof Let $\varphi$ be an arbitrary Grundy coloring of $L$, and consider the stable set $S$ formed by the vertices of color 1 under $\varphi$. Since every vertex of higher color has a neighbor of color 1, the set $S$ is a maximal stable set of $L$. Thus, by Claim 8 the subgraph $L - S$ satisfies property (II). Now Claim 5 implies that every Grundy coloring of $L - S$ uses at most 2 colors. This implies $\Gamma(G) \leq 3$, whereas the presence of a subgraph $K_3$ induced by $\{u_\ell, q_1, q_2\}$ yields equality. $\square$

11
To get a general construction of a graph that realizes \((f, g, h)\) with \(2h - f + 1\) vertices, it is enough to repeat the process of adding a clique of order \(f - 3\), as we did at the end of the proof of Theorem 1. This completes the proof of Lemma 3. ✷

In this way Theorem 2 has been proved as well. ✷

4 The lists of extremal graphs

Our goal in this section is to prove Theorem 3. Along the proof we shall also describe the structure of extremal graphs that we call here \(h\)-optimal graphs.

Definition 1 Suppose \(h \geq 4\). We say that a graph \(G = (V, E)\) is \(h\)-optimal if \(\chi(G) = \Gamma(G) = 3\), \(\psi(G) = h\) and \(|V(G)| = 2h - 2\).

In the following statements \(G\) will be an \(h\)-optimal graph and \(\mathcal{H}\) will be an arbitrary, fixed complete \(h\)-coloring of \(G\). Let us also recall that \(\ell = h - 2\). The results in Section 3 directly imply the following

Claim 10 In an \(h\)-optimal graph, there are exactly two color classes of one element and exactly \(\ell\) classes of two elements in \(\mathcal{H}\). ✷

Definition 2 The color classes consisting of two elements will be called \(pairs\). For a vertex \(x\) in the pair, the other vertex will be denoted mostly by \(x'\); they will be the \(couples\) of each other.

Notation We denote by \(\phi_1\) and \(\phi_2\) the two vertices of the singleton color classes, and we set \(\Phi = \{\phi_1, \phi_2\}\). The pairs will be denoted by \(M_1, M_2, \ldots, M_\ell\) and \(M\) will be their union. Moreover, \(F_i\) is the subgraph induced by the vertex set \(M_i \cup \Phi\).

Claim 11 For any \(1 \leq i \leq \ell\), the subgraph \(F_i\) is isomorphic to a \(P_4\) or it contains a triangle as a subgraph. Consequently, \(\Gamma(F_i) = 3\).

Proof Simply we use the fact that \(\phi_1\) and \(\phi_2\) are adjacent and because of the completeness of the coloring \(\mathcal{H}\), both of them have at least one neighbor in \(M_i\). The last statement follows from the monotonicity of \(\Gamma\), and simple facts that \(\Gamma(P_4) = \Gamma(K_3) = 3\) and that the only 4-vertex graph having Grundy number greater than 3 is \(K_4\). ✷

Definition 3 If \(F_i\) is isomorphic to \(P_4\), then \(M_i\) is called a \(pair\) of \(P_4\)-\(type\), otherwise we call it a \(pair\) of \(K_3\)-\(type\).

Notation Let \(S_i\) be any maximal stable set of \(G\) containing \(M_i\).

Claim 12 For \(1 \leq i, j \leq \ell\), the pairs \(M_i\) and \(M_j\) are joined by exactly one edge.
Proof The completeness of $H$ implies that $S_i$ is disjoint from $\Phi$. Furthermore, because of $\Gamma(F_j) = 3$, $S_i$ has to intersect $F_j$ in some vertex, by Claim 4. Consequently, $S_i \cap M_j \neq \emptyset$. Similarly we obtain $S_j \cap M_i \neq \emptyset$. These conditions (two empty triples inside $M_i \cup M_j$) leave room for just one edge between $M_i$ and $M_j$. $\square$

Claim 13 If $u \in M_i$ and $\{\phi_1, \phi_2, u\}$ induces $K_3$, then $u$ is an isolated vertex in $G[M]$. $\square$

Proof Let $H$ be a triangle induced by $\{\phi_1, \phi_2, u\}$. Assume on the contrary that $u$ has a neighbor in $M_j$ for some $j \neq i$. Then the set $S_j$ is disjoint from $V(H)$ and dominates $H$, which implies $\Gamma(G) > 3$, by Claim 4. A contradiction. $\square$

From Claims 11 and 13 we obtain

Corollary 1 If a pair has no isolated vertex in $G[M]$, then it is of $P_4$-type. $\square$

Definition and notation Let $J$ be the union of the pairs containing some isolated vertex of the graph $G[M]$. In what follows we say that a vertex is non-isolated if it is not isolated in $G[M]$. Let $T = M \setminus J$.

In a series of the three subsequent claims we reveal the structure of the graph induced by $T$. Next, in Lemma 4 we analyze the number of pairs in the set $J$.

Claim 14 $T$ induces a bipartite graph.

Before we prove Claim 14 we give some definitions and state some facts.

Definition 4 An induced $P_4$ of $G$ with the middle edge $\phi_1 \phi_2$ will be called an emphasized $P_4$.

Proposition 2 If a maximal stable set $S$ contains some pair then it intersects each emphasized $P_4$ in at least one endvertex.

Proof As we know from Claim 4, the set $S$ intersects every $P_4$. By assumption, $S$ contains some pair $M_i$. Using the properties of the complete coloring, both $\phi_1$ and $\phi_2$ have some neighbor in $M_i$. Therefore $\phi_1, \phi_2 \notin S$ and hence $S \cap P_4$ must be an endvertex. $\square$

Now, let us define the following sets of vertices:

$X = \{x \mid x \in T \text{ and } x \text{ is adjacent to } \phi_2\}$,

$Y = \{y \mid y \in T \text{ and } y \text{ is adjacent to } \phi_1\}$.

By Claim 13 $T$ is the disjoint union of $X$ and $Y$, moreover, $|X| = |Y|$.

Proposition 3 For any vertex $x \in X$, there exists a maximal stable set $S$ containing some pair but not containing $x$. The same is true for any $y \in Y$, too.
Proof By definition, every vertex in $T$ is non-isolated in $G[M]$. Since $x \in T$, there exists a vertex $z$ adjacent to $x$ such that $z \in M_i$ for some $i$. The set $S_i$ above can play the role of $S$ in the proposition.

Proof of Claim 14 We show that $Y$ does not induce any edges. For $X$, the proof is analogous.

Suppose $\eta_1, \eta_2 \in Y$ and $\eta_1, \eta_2$ are adjacent. Then $\{\eta'_1, \phi_2, \phi_1, \eta_2\}$ induces a $P_4$ because $\eta_2$ has exactly one neighbor in $\{\eta'_1, \eta_1\}$. By Proposition 3, we have a maximal stable set $S$ containing some pair with $\eta'_1 \notin S$. By Proposition 2, $S$ intersects both induced 4-paths $\eta'_1 \phi_1 \phi_2 \eta_1$ and $\eta'_1 \phi_1 \phi_2 \eta_2$, in one of their endvertices. It does not contain $\eta'_1$, thus it must contain both $\eta_1$ and $\eta_2$, a contradiction.

Claim 15 $T$ induces a $2K_2$-free graph.

Proof Assume on the contrary that we have a $2K_2$ in $G[T]$. We denote its edges by $xy$ and $\overline{xy}$. Take the 6-vertex subgraph $H$ of $G$ induced by $\{x, \overline{x}, y, \overline{y}, \phi_1, \phi_2\}$. The subgraph $H$ has a maximal stable set $\{x, y\}$ and the remaining graph is a $P_4$, because of the definition of the sets $X$ and $Y$. By Claim 4, we get $\Gamma(H) > 3$, a contradiction.

Let $\tau$ be the number of pairs in $T$. It is a well-known fact that for a bipartite graph with partite sets $X, Y$ of the same cardinality, $2K_2$-freeness is equivalent to the following.

Property $(\ast)$: $X$ and $Y$ can be ordered in such a way that $X = (x_1, x_2, \ldots, x_\tau)$, $Y = (y_1, y_2, \ldots, y_\tau)$, and $N(x_i) \subseteq N(x_j)$ for every $i < j$ and $N(y_i) \supseteq N(y_j)$ for every $i < j$.

In the next claim we use the extended graphs $B'$ defined in Section 3.

Claim 16 The set $T$ induces a graph isomorphic to the graph $B'_\tau$.

Proof Let us pick a counterexample $T$ of smallest size. We state that in $T$ the couple of $x_1$ is $y_1$. Suppose, for a contradiction, that the couple of $x_1$ is $y_j$, for some $j > 1$. The pair $x_1y_1$ cannot be an edge since otherwise, by Property $(\ast)$, $y_1$ would be adjacent to everything in $X$ and it would not have any couple. From the nonadjacency of $x_1$ and $y_1$ and Property $(\ast)$, $x_1$ is isolated in $T$. Consequently, $y_j$ has some neighbor in every class of the complete coloring, except its own class $\{x_1, y_j\}$. Since $G[T]$ is bipartite, $y_j$ is adjacent to all the vertices in $X \setminus x_1$. By Property $(\ast)$, $y_1$ is also adjacent to these vertices. Consequently, the only couple of $y_1$ could be $x_1$, a contradiction. Thus, the couple of $x_1$ is $y_1$ indeed.

Taking the graph induced by $T' = T \setminus \{x_1, y_1\}$, would be a smaller counterexample. Claim 16 is proved.

The next step is to manage the isolated vertices of $G[M]$. 14
**Lemma 4**  The set $J$ contains exactly two pairs.

**Proof**  Let $\xi$ be the number of pairs in $J$.

**Claim 17**  $\xi \leq 2$

**Proof**  The assertion obviously holds for $\ell = 2$. Hence assume that $\ell \geq 3$.

Suppose for a contradiction that $\xi \geq 3$. Without loss of generality, we may assume that $M_i = \{u_i, u'_i\}$, $i \in \{1, 2, 3\}$ are arbitrary pairs in $J$ such that $u_i$ is isolated in $G[M]$. By the completeness of the coloring $\mathcal{H}$, the non-isolated vertices $u'_i$ of pairs $M_i$ are mutually adjacent. In what follows we use $Q$ to denote the complete subgraph induced by $\{u'_1, u'_2, u'_3\}$.

If $\ell \geq 4$, then there exists a pair $M_j = \{r, r'\}$, $j \geq 3$. For each $i \in \{1, 2, 3\}$, consider the edge $e_i$ between $M_i$ and $M_j$. Obviously, $e_i$ contains $u'_i$. Consequently, the stable set $\{r, r'\}$ dominates $Q$. Using Claim 4 we obtain a contradiction. Hence it remains to consider the case when $\ell = 3$.

Let $\ell = 3$ and assume for a contradiction that $\xi \geq 3$, which in this case, by $\xi \leq \ell$, means $\xi = 3$. Also recall that under such assumptions we consider only 8-vertex graphs.

Now, observe that for $i \in \{1, 2\}$ the vertex sets $N_i = V(Q) \setminus N(\phi_i)$ have the following properties:

1. $N_1 \cup N_2 = Q$.
2. Suppose not. Then, considering some uncovered vertex, it would be isolated in $G[M]$ (by Claim 13), contradicting the completeness of the coloring $\mathcal{H}$.
3. $N_1 \cap N_2 \neq \emptyset$.
4. Taking the triangle induced by $\{\phi_2, u'_2, u'_3\}$ and the stable set $M_1$ which dominates this triangle, we get a contradiction by Claim 4.

Thus we may assume that $N_1$ and $N_2$ have some common vertex, say $u'_1$. Hence, by the completeness of the coloring $\mathcal{H}$, it holds that $\phi_1 u_1 \in E$ and $\phi_2 u_1 \in E$.

Between the two sets $\{\phi_1, \phi_2\}$ and $\{u'_2, u'_3\}$ we have some edge, because of the connectedness condition, say $\phi_2 u'_2 \in E$. This implies $\phi_1 u'_2 \notin E$, since otherwise we would contradict (I).

In order to avoid the $P_4$ induced by $\{\phi_1, \phi_2, u'_2, u'_3\}$ and dominated by the stable set $M_1$, we state that, by (I), either $\phi_1 u'_3$ or $\phi_2 u'_3$ is an edge. If $\phi_2 u'_3 \in E$, then the triangle induced by $\{\phi_2, u'_2, u'_3\}$ is dominated by $M_1$, a contradiction by Claim 4. Hence $\phi_2 u'_3 \notin E$, and consequently $\phi_1 u'_3 \in E$. However, in this case the $P_4$ induced by $\{u_1, \phi_1, u'_3, u'_2\}$ is dominated by the stable set $\{\phi_2, u'_2\}$. Since this cannot be affected by any further edges, we get a contradiction by Claim 4.  \qed
Claim 18 \( \xi \geq 2 \).

Proof If \( h = 4 \), then the assertion holds, since by Claim 12, each of the two pairs contains exactly one vertex that is isolated in \( G[M] \). In what follows we assume that \( h \geq 5 \).

Case 1 We prove \( \xi \neq 0 \).

Suppose that \( \xi = 0 \). By Claim 16 it holds that \( G[T] \) is isomorphic to \( B'_1 \). There are two isolated vertices in this graph but \( M = T \), by the assumption of the claim, which means that there is no isolated vertex in \( M \), a contradiction.

Case 2 We prove \( \xi \neq 1 \).

Let \( M_1 = \{u_1, u'_1\} \) be a pair with \( u_1 \) being isolated in \( G[M] \), and let \( M_i = \{u_i, v_i\} \), \( i \in \{2, \ldots, \ell\} \) be the pairs that have no vertices that are isolated in \( G[M] \), consequently, the pairs of \( P_{\ell}-\text{type} \). Assume that \( \{u_2, \ldots, u_{\ell}\} \) are adjacent to \( \phi_1 \), while \( \{v_2, \ldots, v_{\ell}\} \) to \( \phi_2 \), and consider \( M_1 \), two distinct pairs \( M_i, M_j \) chosen arbitrarily from \( M \setminus J \). Recall, that by Claim 12 there are exactly three edges between the vertices of \( M_1, M_i \) and \( M_j \), while by Claim 16 it holds that \( u_i u_j, v_i v_j \notin E \). Consequently, we have three possibilities:

(a) \( u'_1 v_i, u'_1 u_j, u_i v_j \in E \),

(b) \( u'_1 v_i, u'_1 u_j, v_i u_j \in E \),

(c) \( u'_1 v_i, u'_1 v_j, u_i v_j \in E \).

By symmetry, and by Claim 14 there are no further possibilities. Also note, that besides the above-mentioned edges it will be enough to consider the edges between \( \Phi \) and \( M_1 \) and that by Claim 13 the vertex \( u'_1 \) cannot be a common neighbor of \( \phi_1 \) and \( \phi_2 \).

We start with a simultaneous analysis of (a) and (b). Assume that \( \phi_2 u'_1 \in E \). Then (a) implies that a path \( P_1 \) induced by \( \{u_j, \phi_1, \phi_2, v_j\} \) is dominated by \( \{u_1, u'_1\} \), while from (b) we obtain a triangle induced by \( \{\phi_2, u'_1, v_i\} \) and dominated by \( M_j \). Since this cannot be affected by adding any further edges, \( \phi_2 u'_1 \notin E \) and hence, by completeness, \( \phi_2 u_1 \) must be an edge. If so, then for (a), independently of whether \( \phi_1 u_1 \in E \) or \( \phi_1 u'_1 \in E \), a path \( P_1 \) induced by \( \{u_j, \phi_1, \phi_2, v_j\} \) is dominated by \( M_1 \). Now, for (b), if \( \phi_1 u'_1 \notin E \), then \( \{u_1, u'_1\} \) dominates a path \( P_1 \) induced by \( \{u'_1, v_i, \phi_2, \phi_1\} \). On the other hand, if \( \phi_1 u'_1 \in E \), then a triangle induced by \( \{\phi_1, u_j, u'_1\} \) is dominated by \( M_i \). Note that the analysis in case (b) is independent of whether \( \phi_1 u_1 \) is an edge.

Hence \( \phi_2 u_1 \notin E \) and it finally follows that neither \( \phi_2 u'_1 \) nor \( \phi_2 u_1 \) is an edge, which contradicts the completeness of the coloring \( \mathcal{H} \).

It remains to consider case (c). First, observe that whenever all pairs \( M_i, M_j \), \( i, j \in \{2, \ldots, \ell\} \) satisfy \( u'_1 v_i, u'_1 v_j, u_i v_j \in E \), then \( u'_1 \) is adjacent to each vertex in \( \{v_2, \ldots, v_\ell\} \). Now, considering adjacencies between the pairs in \( M \setminus J \), by Claim 16
either $v_2, u_\ell$ or $v_\ell, u_2$ are isolated in $G[M \setminus J]$. Extending the scope to $G[M]$, both $v_2$ and $v_\ell$ become neighbors of $u'_1$, but either $u_\ell$ or $u_2$ remains isolated. This clearly contradicts our assumption that $\xi = 1$. □

We have shown Claims 17 and 18, and thus Lemma 4 as well. □

Let $L_0, L_1$ and $L_2$ be the graphs presented in Figure 5.

**Lemma 5** If $h = 5$, then a graph $G$ is $h$-optimal if and only if it is isomorphic to one of the graphs in \{ $L_0, L_1, L_2$ \}.

**Proof** By Lemma 4 a graph $G$ contains exactly one pair of $P_4$-type that consists of non-isolated vertices. Let $M_3 = \{u_3, v_3\}$ be such a pair. For $i \in \{1, 2\}$ let $M_i = \{u_i, u'_i\}$ be the pairs having $u_i$ isolated in $G[M]$.

Observe that $u'_1$ and $u'_2$ are adjacent and each of them must have some neighbor in $M_3$. Moreover, since vertices in $M_3$ are non-isolated, by Claim 12 the neighbors of $u'_1, u'_2$ in $M_3$ must be disjoint. Without loss of generality we may assume that $u'_1u_3, u'_2v_3 \in E$. By Claim 12 there are no other edges between $M_1, \ldots, M_3$, so it remains to consider the edges incident to $\phi_1$ or $\phi_2$.

Since $M_3$ is of $P_4$-type, assume that $\phi_1u_3, \phi_2v_3 \in E$ and consequently $\phi_1v_3, \phi_2u_3 \notin E$. Now, if both $\phi_2u'_1 \in E$ and $\phi_2u'_2 \in E$, then $M_3$ dominates a triangle induced by $\{\phi_2, u'_1, u'_2\}$, a contradiction. This cannot be affected by any further edges and hence $\phi_2$ cannot be simultaneously adjacent to $u'_1$ and $u'_2$. Consequently, by completeness, $\phi_2$ must be adjacent to at least one vertex in $\{u_1, u_2\}$.

**Case 1** Assume that $\phi_2u'_1 \in E$ and $\phi_2u'_2 \notin E$.

Consequently, by completeness $\phi_2u_2 \in E$. By Claim 13 we have $\phi_1u'_1 \notin E$ and hence $\phi_1u_1 \in E$. However, since the current graph is bipartite, we need to consider further edges. If $\phi_1u'_2 \notin E$, then $M_3$ dominates a path $P_4$ induced by $\{\phi_1, \phi_2, u'_1, u'_2\}$,
and this cannot be altered neither by $\phi_2u_1$ nor by $\phi_1u_2$. Hence $\phi_1u'_2 \in E$. The graph is still bipartite. Now, adding either $\phi_2u_1$ or $\phi_1u_2$ results in the graph $L_1$, while adding both edges gives the graph $L_2$.

Case 2 Assume that $\phi_2u'_2 \in E$ and $\phi_2u'_1 \notin E$.

From Claim 13 it follows that $\phi_1u'_2 \notin E$, while by completeness $\phi_1u_1 \in E$ or $\phi_1u'_1 \in E$. Assume that $\phi_1u'_1 \in E$ and consider a subgraph $H$ induced by $\Phi \cup M \setminus \{u_1, u_2\}$. Then a path $P_4$ induced by $\{\phi_1, u'_1, u'_2, v_3\}$ is dominated by $\{\phi_2, u_3\}$. Hence $\phi_1u'_1 \notin E$. This in turn results in a graph containing a subgraph $P_4$ induced by $\{\phi_1, \phi_2, u'_1, u'_2\}$ and dominated by $M_3$. Since there are no further edges that could be added between vertices of $H$, we get a contradiction by Claim 4.

Case 3 Assume that $\phi_2u'_1, \phi_2u'_2 \notin E$.

By completeness, $\phi_2u_1, \phi_2u_2 \in E$. Note that it remains to consider the edges incident to $\phi_1$. Consider a subgraph $H$ induced by $\Phi \cup M \setminus \{u_1, u_2\}$. To argue that either $\phi_1$ is adjacent to both $u'_1$ and $u'_2$ or to none of them observe that whenever only one of the edges is present, then $M_3$ dominates a path $P_4$ induced by $\{\phi_1, \phi_2, u'_1, u'_2\}$. On the other hand, if we assume that both edges are present, then $M_3$ dominates a triangle induced by $\{\phi_1, u'_1, u'_2\}$. If both edges are missing, then by completeness $\phi_1u_1, \phi_2u_2 \in E$, and we get the graph $L_0$, that obviously realizes a triple $(3,3,5)$. Thus, either we get a $h$-optimal graph $L_0$ or a contradiction by Claim 4.\)

It is not hard to see that the arguments analogous to those in the proof of Lemma 5 can be used to obtain the list of all graphs that are $h$-optimal for $h = 4$. Let $L_1, \ldots, L_7$ be the graphs presented in Figure 5.

**Lemma 6** If $h = 4$, then a graph $G$ is $h$-optimal if and only if it is isomorphic to one of the graphs in $\{L_1, \ldots, L_7\}$.

### 4.1 End of the proof of Theorem 5 for $h \geq 6$

By the analysis above, to complete the proof of Theorem 5 it remains to focus on $J$ and $\Phi$ when $h \geq 6$.

**Notation** Let $v_1, v_2$ be the vertices that are isolated in $G[M]$, and let $v_1, v_2$ be their couples, respectively. Let $M_i = \{u_i, v_i\}$, $i \in \{1, \ldots, \tau\}$ be the pairs in $T$, that is, the pairs without isolated vertices. Recall that $\tau = \ell - 2 = h - 4$.

The results on $2K_2$-free bipartite graphs entitle us to suppose that the set of edges in $G[T]$ is $\{u_i, v_i \mid I \supset i\}$.

**Claim 19** $\{j \mid v_jv_1 \in E\}$ and $\{k \mid u_kv_1 \in E\}$ are intervals. (Here the empty set is also considered as an interval.)
Figure 6: The seven 4-optimal graphs and their achromatic colorings

**Proof** Suppose first that there are subscripts $j$ and $k > j$ such that $\nu_1 v_j \in E$ and $\nu_1 u_k \in E$. Then we would have a stable set $\{t_1, \nu_1\}$ dominating the $P_4$ induced by $\{u_k, \phi_2, \phi_1, v_j\}$, a contradiction. (The relation of $\phi_1$ and $\phi_2$ to the other vertices can be read out from the proof of Claim 14.)

The vertex $\nu_1$ is adjacent to exactly one of $u_i, v_i$ for every $i$. Thus, denoting the neighbor of $\nu_1$ in $Y$ with the smallest subscript by $v_j$, $N(\nu_1) \cap Y = \{v_j, v_{j+1}, \ldots, v_\tau\}$ and $N(\nu_1) \cap X = \{u_1, u_2, \ldots, u_{j-1}\}$.

**Claim 20** One of $N(\nu_i) \cap X, N(\nu_i) \cap Y$ ($i \in \{1, 2\}$) is empty.

**Proof** Otherwise $\{\nu_1, \nu_2, u_i, v_i\}$ would induce a $K_4$ and the Grundy number would be greater than 3.

We may assume $N(\nu_2) \cap X = \emptyset$. Then

**Claim 21** (a) $N(\nu_2) \cap Y = Y$, (b) $N(\nu_1) \cap Y = \emptyset$ and (c) $N(\nu_1) \cap X = X$.

**Proof** (a) is an obvious consequence of the assumption.

Suppose $N(\nu_1) \cap Y$ is a nonempty proper subset of $Y$. If there was a $j$ such that $v_j \nu_1 \in E$ and $v_{j-1} \nu_1 \notin E$, then the stable set $\{u_{j-1}, v_{j-1}\}$ would dominate the triangle induced by $\{\nu_1, \nu_2, v_j\}$, a contradiction. Consequently, if the Claim was not true, then such a $j$ would not exist.
If \( N(\nu_1) \cap Y = Y \) then one can find the stable set \( \{u_1, v_1\} \) that dominates the triangle induced by \( \{\nu_1, \nu_2, v_2\} \), a contradiction again. (Note that we used \( h \geq 6 \).

Otherwise, \( N(\nu_1) \cap Y = \{v_1, v_2, \ldots, v_j\} \) for some \( j < \tau \). Thus \( \nu_1v_{j+1} \notin E \) and \( \nu_1u_{\tau+1} \in E \), contradicting the arguments in the proof of Claim 19. This implies the validity of (b), from which (c) follows.

Now we can concentrate on the 8 pairs of vertices between the sets \( \{\phi_1, \phi_2\} \) and \( \{\nu_1, \nu_2, \iota_1, \iota_2\} \) since these are the remaining undetermined ones. First we prove

**Claim 22** \( \nu_2\phi_1 \notin E \) (and \( \nu_1\phi_2 \notin E \)).

**Proof** Otherwise the stable set \( \{u_1, v_1\} \) would dominate the triangle induced by \( \{\nu_2, \phi_1, v_\tau\} \). (The same works for the second statement.)

**Claim 23** \( \nu_1\phi_1 \in E \) (and \( \nu_2\phi_2 \in E \)).

**Proof** Suppose \( \nu_1\phi_2 \notin E \). Then the stable set \( \{\nu_1, \phi_1\} \) dominates the \( P_4 \) induced by \( \{v_1, \nu_2, v_2, u_1\} \). (The same works for the second statement.)

The completeness of the coloring implies \( \iota_2\phi_1 \in E \) and \( \iota_1\phi_2 \in E \). The last fact we need is

**Claim 24** It is impossible that both \( \iota_1\phi_1 \) and \( \iota_2\phi_2 \) are non-edges.

**Proof** In this case the whole graph would be bipartite (with partite sets \( X \cup \{\phi_1, \nu_2, \iota_1\} \) and \( Y \cup \{\phi_2, \nu_1, \iota_2\} \)), a contradiction with the assumptions.

Now we identify the notation above with that of the examples in Figure 3 in the following way: \( \phi_1 \rightarrow q_2, \phi_2 \rightarrow q_1, \iota_1 \rightarrow u_{\tau+1}, \iota_2 \rightarrow w_1 \).

Let us look now at the graphs \( L_1 \) and \( L_2 \). In both graphs \( \iota_2q_2 \in E \), moreover \( \iota_2 \) and \( \phi_2 \) are adjacent in \( L_1 \), while they are non-adjacent in \( L_2 \). The only further possible situation would be the converse but this would yield a graph isomorphic to \( L_2 \), \( L_1 \) respectively.

This completes the proof of Theorem 3.

**5 Concluding remarks**

In this paper, for all realizable triples \( (f, g, h) \) of integers, we determined the minimum order of connected graphs \( G \) such that \( \chi(G) = f \), \( \Gamma(G) = g \), and \( \psi(G) = h \). We completely described also the list of graphs attaining the minimum in all cases where \( f < g \leq h \) or \( f = g = 3 \). For the other triples the corresponding characterization of graphs remains unsolved:
**Problem 1** For larger common values $f = g > 3$, and $h > f$, determine the list of $h$-optimal graphs.

Since the clique number is a universal lower bound on the chromatic number, one can study the extended chain of inequalities $\omega(G) \leq \chi(G) \leq \Gamma(G) \leq \psi(G)$. In this context the following problem arises in a natural way:

**Problem 2** Let $2 \leq a \leq b \leq c \leq d$ be integers.

(i) Give necessary and sufficient conditions for the existence of connected graphs $G$ with $\omega(G) = a$, $\chi(G) = b$, $\Gamma(G) = c$, $\psi(G) = d$.

(ii) If such graphs exist, determine their minimum order $n_0 = n_0(a, b, c, d)$, and characterize the graphs whose number of vertices attains this minimum.

Probably, already some particular cases are quite hard:

**Problem 3** Solve the analogous problems for three-element subsets of $\{\omega, \chi, \Gamma, \psi\}$.

Similar characterizations for graphs with restricted structural properties would also be of interest.
