(Communicated by Jinyan Fan)

ABSTRACT. We consider the generalized alternating direction method of multipliers (ADMM) for linearly constrained convex optimization. Many problems derived from practical applications have showed that usually one of the subproblems in the generalized ADMM is hard to solve, thus a special proximal term is added. In the literature, the proximal term can be indefinite which plays a vital role in accelerating numerical performance. In this paper, we are devoted to deriving the optimal lower bound of the proximal parameter and result in the generalized ADMM with optimal indefinite proximal term. The global convergence and the \(O(1/t)\) convergence rate measured by the iteration complexity of the proposed method are proved. Moreover, some preliminary numerical experiments on LASSO and total variation-based denoising problems are presented to demonstrate the efficiency of the proposed method and the advantage of the optimal lower bound.

1. Introduction. In this paper, we consider the following linearly constrained convex optimization problem

\[
\min \{\theta_1(x) + \theta_2(y) \mid Ax + By = b, \; x \in \mathcal{X}, \; y \in \mathcal{Y}\},
\]

where \(A \in \mathbb{R}^{m \times n_1}, \; B \in \mathbb{R}^{m \times n_2}, \; b \in \mathbb{R}^m, \; \mathcal{X} \subset \mathbb{R}^{n_1} \text{ and } \mathcal{Y} \subset \mathbb{R}^{n_2} \) are closed convex sets, \(\theta_1 : \mathbb{R}^{n_1} \rightarrow \mathbb{R}\) and \(\theta_2 : \mathbb{R}^{n_2} \rightarrow \mathbb{R}\) are convex (not necessarily smooth) functions. The model (1.1) with separable structure captures a variety of applications in signal processing, computer vision and statistical learning, see e.g., [1, 3, 4, 31, 34, 35, 37] and references therein for more details. Throughout this paper, the solution set of (1.1) is assumed to be nonempty and the matrix \(B\) is full column rank. The augmented Lagrangian function of (1.1) is defined as

\[
L_\beta(x, y, \lambda) = \theta_1(x) + \theta_2(y) - \lambda^T(Ax + By - b) + \frac{\beta}{2} \|Ax + By - b\|^2,
\]

where \(\lambda \in \mathbb{R}^m\) is the Lagrangian multiplier and \(\beta > 0\) is a penalty parameter.

It is well known that alternating direction method of multipliers (ADMM) is an efficient approach for solving the problem (1.1), which originally proposed in [13, 16]. This method treats the functions \(\theta_1\) and \(\theta_2\) individually and makes the subproblems easier to solve than the original one (1.1). Recently, due to its high efficiency, the
ADMM has been applied in a broad spectrum of areas such as signal processing [5, 6, 7], image restoration and denoising [12, 33], and sparse signal recovery [10]. We refer to [2, 9, 15, 17] for some reviews on ADMM.

In order to further accelerate the numerical performance of the original ADMM, a generalized ADMM was proposed in [8] and extensively studied in [8, 11, 27]. The scheme of the generalized ADMM is

$$\begin{align}
x^{k+1} &= \arg \min \{ \theta_1(x) - x^T A^T \lambda^k + \frac{\beta}{2} \| Ax + By - b \|^2 | x \in X \}, \\
y^{k+1} &= \arg \min \{ \theta_2(y) - y^T B^T \lambda^k + \frac{\beta}{2} \| (\alpha Ax^{k+1} - (1-\alpha)(By^{k+1} - b)) + By - b \|^2 | y \in Y \}, \\
\lambda^{k+1} &= \lambda^{k} - \beta ((\alpha Ax^{k+1} - (1-\alpha)(By^{k} - b)) + By^{k+1} - b),
\end{align}$$

where the parameter \( \alpha \in (0, 2) \) is a relaxation factor. Apparently, the generalized ADMM (1.2) reduces to the original ADMM when \( \alpha = 1 \). The generalized ADMM inherits the whole advantages of the original ADMM and usually performs better in numerical experiments with some values \( \alpha \in (1, 2) \), see e.g., [8, 11]. Indeed, the scheme (1.2) is equivalent to

$$\begin{align}
x^{k+1} &= \arg \min \{ \mathcal{L}_\beta(x, y^k, \lambda^k) | x \in X \}, \\
\lambda^{k+\frac{1}{2}} &= \lambda^{k} - r \beta (Ax^{k+1} + By^k - b), \\
y^{k+1} &= \arg \min \{ \mathcal{L}_\beta(x^{k+1}, y, \lambda^{k+\frac{1}{2}}) | y \in Y \}, \\
\lambda^{k+1} &= \lambda^{k+\frac{1}{2}} - \beta (Ax^{k+1} + By^{k+1} - b),
\end{align}$$

where \( r = \alpha - 1 \).

However, the efficiency of the generalized ADMM (1.3) largely relies on the solving difficulty of the subproblems (1.3a) and (1.3c). Usually, when applying the generalized ADMM for solving some concrete applications such as low-rank optimization problem [36] and the models considered in [38], one of the subproblems is relatively easy to solve and the other one is difficult because the corresponding coefficient matrix is somewhat complicated. Therefore, we assume that the subproblem (1.3a) is easy to solve throughout this paper. While for another subproblem (1.3c), instead of solving itself, a proximal term \( \| y - y^k \|_D^2 \) is added, thus a new scheme is produced as follows

$$\begin{align}
x^{k+1} &= \arg \min \{ \mathcal{L}_\beta(x, y^k, \lambda^k) | x \in X \}, \\
\lambda^{k+\frac{1}{2}} &= \lambda^{k} - r \beta (Ax^{k+1} + By^k - b), \\
y^{k+1} &= \arg \min \{ \mathcal{L}_\beta(x^{k+1}, y, \lambda^{k+\frac{1}{2}}) + \frac{1}{2} \| y - y^k \|_D^2 | y \in Y \}, \\
\lambda^{k+1} &= \lambda^{k+\frac{1}{2}} - \beta (Ax^{k+1} + By^{k+1} - b),
\end{align}$$

where \( D \) is a positive definite matrix. If we choose a special form of \( D \), i.e.,

$$D = \rho I - \beta B^T B \quad \text{with} \quad \rho > \beta \| B^T B \|,$$

the subproblem (1.4c) is the linearized version of (1.3c). The solution of (1.4c) can be obtained via

$$y^{k+1} = \arg \min \{ \theta_2(y) + \frac{\rho}{2} \| y - (y^k + q_k) \|^2 | y \in Y \},$$
where
\[ q_k = \frac{1}{\rho} B^T \left( \lambda^{k+\frac{1}{2}} - \beta (Ax^{k+1} + By^k - b) \right). \]  

(1.7)

We name (1.4) with special \( D \) defined in (1.5) proximal generalized ADMM (PG-ADMM for short). Compared with (1.3c), the problem (1.6) is usually easier to solve if the proximal mapping of \( \theta_2 \), such as the soft-thresholding operator for \( l_1 \)-norm minimization [35], is easy to evaluate. The PG-ADMM (1.4) is similar to the method proposed in [11] where they added the proximal term to the \( x \)-subproblem.

Motivated by the very recent work [22], in this paper, we further relax the requirement of the proximal matrix \( D \) in (1.4) and substituted the proximal term in (1.4c) with \( \frac{1}{2} \|y - y^k\|^2_{D_0} \), where
\[ D_0 = \tau \rho I - \beta B^T B, \quad 0.75 < \tau < 1 \quad \text{and} \quad \rho > \beta \|B^T B\|. \]  

(1.8)

It is easy to see that the matrix \( D_0 \) defined in (1.8) is not necessarily positive definite. They also gave a simple counterexample to illustrate that 0.75 is the optimal lower bound of \( \tau \).

For the PG-ADMM (1.4), Gao and Ma [14] also relaxed the requirement of the positive definiteness of \( D \) in (1.4c) and proposed the positive-indefinite proximal symmetric ADMM (PID-SADMM)
\[
\begin{align*}
    x^{k+1} &= \arg \min \{ C_\beta(x,y^k,\lambda^k) \mid x \in \mathcal{X} \}, \\
    \lambda^{k+\frac{1}{2}} &= \lambda^k - r \beta (Ax^{k+1} + By^k - b), \\
    y^{k+1} &= \arg \min \{ C_\beta(x^{k+1}, y, \lambda^{k+\frac{1}{2}}) + \frac{1}{2} \|y - y^k\|^2_{D_0} \mid y \in \mathcal{Y} \}, \\
    \lambda^{k+1} &= \lambda^{k+\frac{1}{2}} - \beta (Ax^{k+1} + By^{k+1} - b),
\end{align*}
\]  

(1.9a-d)

where
\[ D_0 = \tau \rho I - \beta B^T B, \quad \text{with} \quad \rho > \beta \|B^T B\| \quad \text{and} \quad \tau \in \left[ \frac{r^2 - r + 4}{r^2 - 2r + 5}, 1 \right). \]  

(1.10)

Although the proximal matrix \( D_0 \) in (1.9c) is not necessarily positive definite, this lower bound \( \frac{r^2 - r + 4}{r^2 - 2r + 5} \) is not optimal, because if set \( r = 0 \), the PID-SADMM reduces to the frame of the IP-LADMM and \( \frac{r^2 - r + 4}{r^2 - 2r + 5} = 0.8 \) instead of the optimal lower bound 0.75. Hence there is a gap between the optimal lower bound and \( \frac{r^2 - r + 4}{r^2 - 2r + 5} \).

Motivated by the very recent work [22], in this paper, we further relax the requirement of the proximal matrix \( D_0 \) and focus on finding the optimal lower bound of \( \tau \) in (1.10). The main contributions of this paper are presented as follows. We propose an indefinite proximal generalized ADMM (IPG-ADMM) and prove the global convergence and a worst \( O(1/t) \) convergence rate of the proposed method by specifying a better domain \( \tau \in \left( \frac{3+r}{4}, 1 \right) \). Besides, we present an example to show that the proposed method is not necessarily convergent when \( \tau \in (0, \frac{3+r}{4}) \), which means that the optimal lower bound of the parameter \( \tau \) in (1.10) should be \( \frac{3+r}{4} \). We also apply the proposed method to solve the LASSO and total variation denoising problems to illustrate its feasibility and efficiency.
The rest of this paper is organized as follows. In Section 2, we summarize some preliminaries that are useful for further analysis. Then, we propose an indefinite proximal generalized ADMM and prove some lemmas for the main convergence analysis in Section 3. The global convergence and the $O(1/t)$ convergence rate are conducted when $\tau \in (\frac{3}{4}, 1)$ in Section 4. In Section 5, we give a simple linear programming example to show the optimality of the parameter $\tau$. Moreover, some numerical experiments are presented to show the efficiency of the IPG-ADMM in Section 6. Finally, we draw some conclusions in Section 7.

2. Preliminaries. In this section, we provide some preliminaries which are useful in later analysis.

2.1. Basic properties and definitions. In this paper, we use $\| \cdot \|$ to represent the Euclidean norm. If $D$ is a $n \times n$ symmetric positive definite matrix and $y$ is a vector in $\mathbb{R}^n$, we use the notation $\| y \|^2_D$ to denote $y^T D y$. Also, we slightly abuse the notation $\| y \|^2_D := y^T D y$ when $D$ is not positive definite. With a little abuse of notation, the columnwise adhesion of column vectors $x$, $y$, and $\lambda$, i.e., $(x^T, y^T, \lambda^T)^T$, is often denoted by $(x, y, \lambda)$ whenever it will not incur any confusion.

We give a simple but useful lemma in the following.

Lemma 2.1. For the vectors $a, b, c, d$ in $\mathbb{R}^n$ and a symmetric positive definite matrix $H \in \mathbb{R}^{n \times n}$, we have the identity

\[(a - b)^T H (c - d) = \frac{1}{2} \left( \|a - d\|^2_H - \|a - c\|^2_H + \|c - b\|^2_H - \|b - d\|^2_H \right).\]

2.2. Variational inequality characterization of (1.1). The Lagrangian function of the problem (1.1) is

\[\mathcal{L}(x, y, \lambda) = \theta_1(x) + \theta_2(y) - \lambda^T (Ax + By - b),\]

which is defined on $\mathcal{X} \times \mathcal{Y} \times \mathbb{R}^n$. In (2.1), $(x, y)$ and $\lambda$ are primal and dual variables, respectively. We call $(x^*, y^*, \lambda^*) \in \mathcal{X} \times \mathcal{Y} \times \mathbb{R}^n$ a saddle point of $\mathcal{L}(x, y, \lambda)$ if the following inequalities are satisfied:

\[\mathcal{L}_{\lambda \in \mathbb{R}^n}(x^*, y^*, \lambda) \leq \mathcal{L}(x^*, y^*, \lambda^*) \leq \mathcal{L}_{x \in \mathcal{X}, y \in \mathcal{Y}}(x, y, \lambda^*),\]

which is equivalent to the following variational inequality system:

\[
\begin{cases}
  x^* \in \mathcal{X}, & \theta_1(x) - \theta_1(x^*) + (x - x^*)^T (-A^T \lambda^*) \geq 0, \quad \forall x \in \mathcal{X}, \\
  y^* \in \mathcal{Y}, & \theta_2(y) - \theta_2(y^*) + (y - y^*)^T (-B^T \lambda^*) \geq 0, \quad \forall y \in \mathcal{Y}, \\
  \lambda^* \in \mathbb{R}^n, & (\lambda - \lambda^*)^T (Ax^* + By^* - b) \geq 0, \quad \forall \lambda \in \mathbb{R}^n.
\end{cases}
\]

This can be written in a compact form:

\[\text{VI}(\Omega, F, \theta) \quad w^* \in \Omega, \quad \theta(u) - \theta(u^*) + (w - w^*)^T F(w^*) \geq 0, \quad \forall w \in \Omega,\]

where

\[
\begin{align*}
  w &= \begin{pmatrix} x \\ y \\ \lambda \end{pmatrix}, \quad u = \begin{pmatrix} x \\ y \end{pmatrix}, \quad F(w) = \begin{pmatrix} -A^T \lambda \\ -B^T \lambda \\ Ax + By - b \end{pmatrix}, \\
  \theta(u) &= \theta_1(x) + \theta_2(y), \quad \text{and} \quad \Omega = \mathcal{X} \times \mathcal{Y} \times \mathbb{R}^n.
\end{align*}
\]

Throughout this paper, we use $\Omega^*$ to denote the solution set of $\text{VI}(\Omega, F, \theta)$, and $\Omega^*$ is nonempty under the previous assumption.
3. Indefinite proximal generalized ADMM. In the PID-SADMM (1.9), the parameter $\tau$ should be larger than $\frac{r^2 - r + 4}{2r^2 - 2r + 5}$ so that the convergence can be guaranteed. However, a large value of $\tau$ in (1.9c) usually leads to slow convergence in practical computation. In this paper, we will reduce the lower bound of $\tau$ to $3 + \frac{r^4}{4}$.

Specifically, the indefinite proximal generalized ADMM (IPG-ADMM) can be read as follows:

\[
\begin{aligned}
&x^{k+1} = \arg \min \{ L_\beta(x, y, \lambda^k) \mid x \in X \}, \\
&\lambda^{k+\frac{1}{2}} = \lambda^k - r \beta (Ax^{k+1} + By^k - b), \\
y^{k+1} = \arg \min \left\{ L_\beta(x^{k+1}, y, \lambda^{k+\frac{1}{2}}) + \frac{1}{2} \| y - y^k \|^2_{D_0} \mid y \in Y \right\}, \\
&\lambda^{k+1} = \lambda^{k+\frac{1}{2}} - \beta (Ax^{k+1} + By^{k+1} - b),
\end{aligned}
\]

where

\[
D_0 = \tau \rho I - \beta B^T B, \quad \rho > \beta \| B^T B \| \quad \text{and} \quad \tau \in \left( \frac{3 + r}{4}, 1 \right). \tag{3.2}
\]

It is easy to verify that $D_0$ in (3.1c) is not necessarily positive definite, which is the reason why we call (3.1) indefinite proximal generalized ADMM. From the definition of $D$ in (1.5), it also holds that

\[
D_0 = \tau D - (1 - \tau) \beta B^T B, \tag{3.3}
\]

Note that the IPG-ADMM (3.1) reduces to the IP-LADMM [22] when $r = 0$.

3.1. A prediction-correction interpretation. In this subsection, we show that the scheme (3.1) can be reformulated to a prediction-correction framework by introducing some auxiliary variables, which plays a vital role in the convergence analysis for (3.1).

The variable $x$ plays an intermediate role in the sense that $x^k$ is not involved in the iteration in (3.1). Therefore, as [2], we still call $x$ an intermediate variable and $(y, \lambda)$ essential variables because they are essentially needed in the iteration. To distinguish their roles, accompanied with the notation in (2.3b), we additionally define the notations

\[
v = \begin{pmatrix} y \\ \lambda \end{pmatrix}, \quad \mathcal{V} = \mathcal{Y} \times \mathbb{R}^m \quad \text{and} \quad \mathcal{V}^* = \left\{ (y^*, \lambda^*) \mid (x^*, y^*, \lambda^*) \in \Omega^* \right\}. \tag{3.4}
\]

Moreover, for the iterate $(x^{k+1}, y^{k+1}, \lambda^{k+1})$ generated by the indefinite proximal generalized ADMM (3.1), we define an auxiliary vector $\check{w}^k = (\check{x}^k, \check{y}^k, \check{\lambda}^k)$ as

\[
\check{x}^k = x^{k+1}, \quad \check{y}^k = y^{k+1}, \quad \check{\lambda}^k = \lambda^{k+1} - \beta (Ax^{k+1} + By^{k+1} - b). \tag{3.5a}
\]

In the following, we show some properties for the auxiliary vector $\check{w}^k$ defined in (3.5).

**Lemma 3.1.** For given $v^k = (y^k, \lambda^k)$, let $w^{k+1}$ be generated by IPG-ADMM (3.1) and $\check{w}^k$ be defined by (3.5). Then, we have

\[
\check{w}^k \in \Omega, \quad \theta(u) - \theta(\check{w}^k) + (w - \check{w}^k)^T F(\check{w}^k) \geq (v - \check{v}^k)^T Q(v^k - \check{v}^k), \quad \forall w \in \Omega, \tag{3.6a}
\]
where
\[
Q = \begin{pmatrix}
\tau \rho I & -rB^T \\
-B & \frac{1}{\beta} I_m
\end{pmatrix}.
\]

Proof. Using the notation defined in (3.5), we can rewrite \(\lambda^{k+\frac{1}{2}}\) in (3.1b) as
\[
\lambda^{k+\frac{1}{2}} = \lambda^k - r(\lambda^k - \tilde{\lambda}^k) = \bar{\lambda}^k + (r-1)(\bar{\lambda}^k - \lambda^k).
\] (3.7)
The optimality condition of the \(x\)-subproblem of (3.1) is, for all \(x \in \mathcal{X}\),
\[
x^{k+1} \in \mathcal{X}, \quad \theta_1(x) - \theta_1(x^{k+1}) + (x - x^{k+1})^T \{-A^T \lambda^k + \beta A^T (A\tilde{x}^{k+1} + By^k - b)\} \geq 0.
\] It follows from the definition of \(\tilde{w}^k\) in (3.5) that
\[
\tilde{x}^k \in \mathcal{X}, \quad \theta_1(x) - \theta_1(\tilde{x}^k) + (x - \tilde{x}^k)^T (-A^T \tilde{\lambda}^k) \geq 0, \quad \forall \ x \in \mathcal{X}.
\] (3.8a)
Substituting the relation (3.7) into the \(y\)-subproblem (3.1c), we have
\[
y^k = \arg \min \{\theta_2(y) - (\bar{\lambda}^k + (r-1)(\bar{\lambda}^k - \lambda^k))^T By \\
+ \frac{\beta}{2} \|A\tilde{x}^k + By - b\|^2 + \frac{1}{2} \|y - y^k\|^2_2 | y \in \mathcal{Y}\}.
\]
Consequently, by using (3.2), we obtain for all \(y \in \mathcal{Y}\) and \(\tilde{y}^k \in \mathcal{Y}\),
\[
\theta_2(y) - \theta_2(\tilde{y}^k) + (y - \tilde{y}^k)^T \begin{cases}
-B^T (\bar{\lambda}^k + (r-1)(\bar{\lambda}^k - \lambda^k)) \\
+ \beta B^T (A\tilde{x}^k + By^k - b) + (\tau \rho I - \beta B^T B)(\tilde{y}^k - y^k)
\end{cases} \geq 0.
\]
Now, we treat the \{\} term in the last inequality. Using \(\beta(A\tilde{x}^k + By^k - b) = -\bar{\lambda}^k - \lambda^k\) (see (3.5b)), we obtain
\[
-B^T (\bar{\lambda}^k + (r-1)(\bar{\lambda}^k - \lambda^k)) + \beta B^T (A\tilde{x}^k + By^k - b) + (\tau \rho I - \beta B^T B)(\tilde{y}^k - y^k)
= -B^T \bar{\lambda}^k + (r-1)B^T (\bar{\lambda}^k - \lambda^k) + \beta B^T B(\tilde{y}^k - y^k)
+ \beta B^T (A\tilde{x}^k + By^k - b) + (\tau \rho I - \beta B^T B)(\tilde{y}^k - y^k)
= -B^T \bar{\lambda}^k - (r-1)B^T (\bar{\lambda}^k - \lambda^k) + \tau \rho(\tilde{y}^k - y^k) - B^T (\bar{\lambda}^k - \lambda^k)
= -B^T \bar{\lambda}^k + \tau \rho(\tilde{y}^k - y^k) - rB^T (\bar{\lambda}^k - \lambda^k).
\] As a result, with the notations \(\bar{w}^k\) and \(\tilde{w}^k\) in (3.5), the optimality condition of the \(y\)-subproblem (3.1c) can be written as
\[
y^k \in \mathcal{Y},
\quad \theta_2(y) - \theta_2(\tilde{y}^k) + (y - \tilde{y}^k)^T \{-B^T \bar{\lambda}^k + \tau \rho(\tilde{y}^k - y^k) - rB^T (\bar{\lambda}^k - \lambda^k)\} \geq 0, \quad \forall y \in \mathcal{Y}.
\] (3.8b)
According to the definition of \(\tilde{w}^k\) in (3.5), we have
\[
(A\tilde{x}^k + By^k - b) - B(y^k - y^k) + \frac{1}{\beta}(\tilde{\lambda}^k - \lambda^k) = 0,
\]
and it can be written as
\[
\tilde{\lambda}^k \in \mathbb{R}^n, \quad (\lambda - \bar{\lambda}^k)^T \{2(A\tilde{x}^k + By^k - b) - B(y^k - y^k) + \frac{1}{\beta}(\bar{\lambda}^k - \lambda^k)\} \geq 0, \quad \forall \lambda \in \mathbb{R}^n.
\] (3.8c)
Combining (3.8a), (3.8b) and (3.8c), and using the notations in (2.3), we obtain the assertion (3.6) immediately. This completes the proof. □

Using the auxiliary variable \(\tilde{\lambda}^k = \lambda^k - \beta(A\tilde{x}^{k+1} + By^k - b)\) in (3.5b), the right-hand side of (3.6a) only involves the essential variables \(\nu\), which makes us able to
merely focus on the essential variables for establishing convergence for the scheme (3.1).

**Lemma 3.2.** For given \(v^k = (y^k, \lambda^k)\), let \(w^{k+1}\) be generated by IPG-ADMM (3.1) and \(\tilde{w}^k\) be defined by (3.5). Then, we have

\[
v^{k+1} = v^k - M(v^k - \tilde{v}^k),
\]

where

\[
M = \begin{pmatrix} I & 0 \\ -\beta B & (r + 1)I_m \end{pmatrix}.
\]

**Proof.** It follows from (3.1) that

\[
\lambda^{k+1} = \lambda^k + \frac{1}{2} - \left(-\beta B(y^k - \tilde{y}^k) + \beta(Ax^{k+1} + By^k - b)\right)
= \lambda^k - r(\lambda^k - \tilde{\lambda}^k) - \left(-\beta B(y^k - \tilde{y}^k) + (\lambda^k - \tilde{\lambda}^k)\right)
= \lambda^k - (-\beta B(y^k - \tilde{y}^k) + (r + 1)(\lambda^k - \tilde{\lambda}^k)).
\]

Together with \(y^{k+1} = \tilde{y}^k\), we build the following useful relationship

\[
\begin{pmatrix} y^{k+1} \\ \lambda^{k+1} \end{pmatrix} = \begin{pmatrix} y^k \\ \lambda^k \end{pmatrix} - \begin{pmatrix} I & 0 \\ -\beta B & (r + 1)I_m \end{pmatrix} \begin{pmatrix} y^k - \tilde{y}^k \\ \lambda^k - \tilde{\lambda}^k \end{pmatrix}.
\]

The proof is completed. ∎

Therefore, based on the previous two lemmas, the scheme (3.1) can be interpreted as a prediction-correction reformulation which consists of the prediction step (3.6) and the correction step (3.9). We thus also frequently call \(\tilde{w}^k\) and \(w^{k+1}\) the predictor and corrector respectively in our proof. However, the prediction-correction reformulation only serves for the convergence analysis and it is unnecessary to divide two stages in practical implementation for the IPG-ADMM (3.1).

### 3.2. Basic properties

Let us define a matrix as

\[
H = \begin{pmatrix} \tau \rho I - \frac{r}{r + 1} \beta B^T B & -\frac{r}{r + 1} B^T \\ -\frac{r}{r + 1} B & (r + 1)\beta I_m \end{pmatrix}.
\]

(3.10)

For the matrices \(Q\) and \(M\) defined in (3.6b) and (3.9b) respectively, it holds that \(Q = HM\). In the following, we show that the matrix \(H\) is positive definite under some mild assumptions.

**Lemma 3.3.** The matrix \(H\) defined in (3.10) is positive definite if

\[
\tau > \frac{3 + r}{4} \quad \text{with} \quad r \in (-1, 1)
\]

(3.11)

and the matrix \(B\) in (1.1) is full column rank.

**Proof.** For any \(\tau > \frac{3 + r}{4}\) with \(r \in (-1, 1)\), we have \(\tau > r\). Then with the definition of \(H\) in (3.10), we know that

\[
H = \begin{pmatrix} \tau \rho I - \frac{r}{r + 1} \beta B^T B & -\frac{r}{r + 1} B^T \\ -\frac{r}{r + 1} B & (r + 1)\beta I_m \end{pmatrix}.
\]
For given Lemma 3.4, better understand the convergence proof for the scheme (3.1). Substituting it into (3.6a) and using the relation $Q$ and $\tilde{H}$ is positive semi-definite, the positive definiteness of $H$ is defined in (3.10) follows immediately.

Proof. First, it follows from the definition of $F$ in (2.3b) that

$$
\theta(u) - \theta(\tilde{u}^k) + (w - \tilde{w}^k)^T F(w) 
\geq \frac{1}{2} (\| v - v^{k+1} \|_H^2 - \| v - v^k \|_H^2) + \frac{1}{2} \| v^k - \tilde{v}^k \|_G^2, \ \forall w \in \Omega,
$$

(3.13)

where $H$ is defined in (3.10) and

$$
G = Q^T + Q - M^T H M.
$$

(3.14)

Proof. First, it follows from the definition of $F$ in (2.3b) that

$$
\theta(u) - \theta(\tilde{u}^k) + (w - \tilde{w}^k)^T F(w) 
\geq \frac{1}{2} (\| v - v^{k+1} \|_H^2 - \| v - v^k \|_H^2) + \frac{1}{2} \| v^k - \tilde{v}^k \|_G^2, \ \forall w \in \Omega.
$$

(3.16)

Applying the Lemma 2.1 to the right-hand side in (3.16) with

$$
a = v, \ b = \tilde{v}^k, \ c = v^k, \ \text{and} \ d = v^{k+1},
$$

we obtain

$$
(v - \tilde{v}^k)^T H (v^k - v^{k+1}) = \frac{1}{2} (\| v - v^{k+1} \|_H^2 - \| v - v^k \|_H^2) + \frac{1}{2} (\| v^k - \tilde{v}^k \|_G^2 - \| v^{k+1} - \tilde{v}^k \|_H^2).
$$

Substituting (3.17) into the right-hand side of (3.16), we obtain for all $w \in \Omega,

$$
\theta(u) - \theta(\tilde{u}^k) + (w - \tilde{w}^k)^T F(w) 
\geq \frac{1}{2} (\| v - v^{k+1} \|_H^2 - \| v - v^k \|_H^2) + \frac{1}{2} (\| v^k - \tilde{v}^k \|_G^2 - \| v^{k+1} - \tilde{v}^k \|_H^2).
$$

(3.17)

For the last term of the right-hand side of (3.17), we have

$$
\begin{align*}
&\| v^k - \tilde{v}^k \|_H^2 - \| v^{k+1} - \tilde{v}^k \|_H^2 \\
&= \| v^k - \tilde{v}^k \|_H^2 - \| (v^k - \tilde{v}^k) - (v^k - v^{k+1}) \|_H^2 \\
&= \| v^k - \tilde{v}^k \|_H^2 - \| (v^k - \tilde{v}^k) - M(v^k - \tilde{v}^k) \|_H^2 \\
&= 2(v^k - \tilde{v}^k)^T H M(v^k - \tilde{v}^k) - (v^k - \tilde{v}^k)^T M T H M (v^k - \tilde{v}^k) \\
&= (v^k - \tilde{v}^k)^T (Q^T + Q - M^T H M) (v^k - \tilde{v}^k).
\end{align*}
$$

(3.10)
Substituting this equation into (3.17) and using the definition of $G$ in (3.14), the assertion of this theorem is proved.

**Theorem 3.5.** For given $v^k = (y^k, \lambda^k)$, let $w^{k+1}$ be generated by IPG-ADMM (3.1) and $\tilde{w}^k$ be defined by (3.5). Then, we have

\[
\|v^{k+1} - v^*\|_H^2 \leq \|v^k - v^*\|_H^2 - \|v^k - \tilde{v}^k\|_G^2.
\]  

**Proof.** By setting $w = w^* \in \Omega^*$ in (3.13) and using (2.3a), we get

\[
\|v^k - v^*\|_H^2 - \|v^{k+1} - v^*\|_H^2 \geq \|v^k - \tilde{v}^k\|_G^2 + 2[\theta(\tilde{u}^k) - \theta(u^*) + (\tilde{w}^k - w^*)^TF(w^*)]
\]

\[
\geq \|v^k - \tilde{v}^k\|_G^2.
\]

The assertion (3.18) follows immediately.

Now we investigate the matrix $G$ defined in (3.14). Since $HM = Q$ and $M^THM = M^TQ$, we have

\[
M^THM = \begin{pmatrix} I & -\beta BT \\ 0 & (r+1)I_m \end{pmatrix} \begin{pmatrix} \tau \rho I & -rB^T \\ -B & \frac{1}{\beta} I_m \end{pmatrix} = \begin{pmatrix} \tau \rho I + \beta BT B & -(r+1)B^T \\ -(r+1)B & \frac{1}{\beta} (r+1) I_m \end{pmatrix}.
\]

Using (3.6b) and the above equation, we have

\[
G = (Q^T + Q) - M^THM
\]

\[
= \begin{pmatrix} 2\tau \rho I & -(r+1)B^T \\ -(r+1)B & \frac{2}{\beta} I_m \end{pmatrix} - \begin{pmatrix} \tau \rho I + \beta BT B & -(r+1)B^T \\ -(r+1)B & \frac{1}{\beta} (r+1) I_m \end{pmatrix}
\]

\[
= \begin{pmatrix} D_0 & 0 \\ 0 & 1 - \frac{r}{\beta} I_m \end{pmatrix},
\]

(3.19)

Since the matrix $D_0$ is indefinite, $G$ is not necessarily positive definite.

When $G$ in (3.14) is positive definite, together with the positive definiteness of $H$, it is relatively easy to prove the global convergence and $!t/T_!$ convergence rate as that in [19, 20, 26]. Since $G$ is not necessarily positive definite, we need further to analyze the properties of $\|v^k - \tilde{v}^k\|_G^2$. In the following, motivated by the techniques in [21, 22, 23, 24, 25], we obtain a lower bound of $\|v^k - \tilde{v}^k\|_G^2$ which is useful for proving the convergence and the convergence rate of IPG-ADMM (3.1).  

**Lemma 3.6.** For given $v^k = (y^k, \lambda^k)$, let $w^{k+1}$ be generated by IPG-ADMM (3.1) and $\tilde{w}^k$ be defined by (3.5). Then, we have

\[
(v^k - \tilde{v}^k)^T G (v^k - \tilde{v}^k)
\]

\[
= \tau \|y^k - y^{k+1}\|_D^2 + (\tau - r) \beta \|B(y^k - y^{k+1})\|^2 + (1 - r) \beta \|Ax^{k+1} + By^{k+1} - b\|^2
\]

\[
+ 2(1 - r) \beta (Ax^{k+1} + By^{k+1} - b)^T B(y^k - \tilde{y}^{k+1}).
\]

(3.20)

**Proof.** According to (3.19), $v = (y, \lambda)$ and $\tilde{y}^k = y^{k+1}$, we have

\[
(v^k - \tilde{v}^k)^T G (v^k - \tilde{v}^k) = \tau \|y^k - y^{k+1}\|_D^2 - (1 - \tau) \beta \|B(y^k - y^{k+1})\|^2 + \frac{1 - r}{\beta} \|\lambda^k - \tilde{\lambda}^k\|^2.
\]

(3.21)
Notice that (see (3.5b))
\[ \lambda^k - \lambda^k = \beta(Ax^{k+1} + By^k - b) = \beta \{ (Ax^{k+1} + By^{k+1} - b) + B(y^k - y^{k+1}) \}. \]
Thus, we have
\[ \|\lambda^k - \lambda^k\|^2 = \beta^2 \| (Ax^{k+1} + By^{k+1} - b) + B(y^k - y^{k+1}) \|^2 \]
\[ = \beta^2 \|Ax^{k+1} + B(y^{k+1} - b)\|^2 + \beta^2 \|B(y^k - y^{k+1})\|^2 \]
\[ + 2\beta^2 (Ax^{k+1} + B(y^{k+1} - b))^T B(y^k - y^{k+1}). \quad (3.22) \]
Substituting (3.22) into the right-hand side of (3.21), we obtain (3.20) immediately.

For the right-hand side of (3.20), there are some quadratic terms involving two consecutive iteration points and it is easy to manipulate them in the convergence proof. Now, we handle the crossing term in the right-hand side of (3.20).

**Lemma 3.7.** For given \( v^k = (y^k, \lambda^k) \), let \( w^{k+1} \) be generated by IPG-ADMM (3.1) and \( \tilde{w}^k \) be defined by (3.5). Then, we have
\[ (y^k - y^{k+1})^T B^T(Ax^{k+1} + By^{k+1} - b) \]
\[ \geq \frac{\tau}{2(1 + r)\beta} \left( \|y^k - y^{k+1}\|^2 - \|y^{k-1} - y^k\|^2 \right) + \frac{1 - \tau}{2(1 + r)} \left( \|B(y^k - y^{k+1})\|^2 \right) \]
\[ - \|B(y^{k-1} - y^k)\|^2 \]  
\[ - \frac{2(1 - \tau) + r}{1 + r} \|B(y^k - y^{k+1})\|^2. \quad (3.23) \]

**Proof.** From the optimality condition of the \( y \)-subproblem (3.1c), for all \( y \in \mathcal{Y} \), it holds that \( y^{k+1} \in \mathcal{Y} \) and
\[ \theta_2(y) - \theta_2(y^{k+1}) + (y - y^{k+1})^T \left( -B^T \lambda^{k+\frac{1}{2}} + \beta B^T(Ax^{k+1} + By^{k+1} - b) \right) \]
\[ + D_0(y^{k+1} - y^k) \geq 0. \quad (3.24) \]
Analagously, for the previous iteration, for any \( y \in \mathcal{Y} \) and \( y^k \in \mathcal{Y} \), it holds that
\[ \theta_2(y) - \theta_2(y^k) + (y - y^k)^T \left( -B^T \lambda^{k-\frac{1}{2}} + \beta B^T(Ax^k + By^k - b) \right) \]
\[ + D_0(y^k - y^{k-1}) \geq 0. \quad (3.25) \]
Setting \( y = y^k \) and \( y = y^{k+1} \) in (3.24) and (3.25), respectively, and then adding them, we get
\[ (y^k - y^{k+1})^T \left( B^T(\lambda^{k+\frac{1}{2}} - \lambda^{k-\frac{1}{2}}) + \beta B^T(Ax^{k+1} + By^{k+1} - b) \right) \]
\[ - \beta B^T(Ax^k + By^k - b) + D_0(y^{k+1} - y^k) - D_0(y^k - y^{k-1}) \geq 0. \quad (3.26) \]
Note that in the \( k \)-th iteration (see (3.1b)), we have
\[ \lambda^{k+\frac{1}{2}} = \lambda^k - r\beta(Ax^{k+1} + By^k - b), \quad (3.27) \]
and in the previous iteration (see (3.1d)),
\[ \lambda^k = \lambda^{k-\frac{1}{2}} - \beta(Ax^k + By^k - b). \quad (3.28) \]
It follows from (3.27) and (3.28) that
\[ \lambda^{k+\frac{1}{2}} - \lambda^{k-\frac{1}{2}} = r\beta(Ax^{k+1} + By^k - b) + \beta(Ax^k + By^k - b) \]
\[ = r\beta(Ax^{k+1} + By^{k+1} - b) + r\beta B(y^k - y^{k+1}) \]
\[ + \beta(Ax^k + By^k - b). \quad (3.29) \]
Substituting (3.29) into (3.26), with a simple manipulation, we have

\[
(y^k - y^{k+1})^T \left( (1+r)\beta B^T(Ax^{k+1} + By^{k+1} - b) + r\beta B^TB(y^k - y^{k+1}) + D_0(y^{k+1} - y^k) - D_0(y^k - y^{k-1}) \right) \geq 0.
\]

Thus,

\[
(y^k - y^{k+1})^T B^T(Ax^{k+1} + By^{k+1} - b) \\
\geq \frac{1}{(1+r)\beta} (y^k - y^{k+1})^T D_0[(y^k - y^{k+1}) - (y^{k-1} - y^k)] \\
- \frac{r}{1+r} \|B(y^k - y^{k+1})\|^2.
\] (3.30)

Besides, note that \(D_0 = \tau D - (1 - \tau)\beta B^TB\), and using the Cauchy-Schwarz inequality, we get

\[
(y^k - y^{k+1})^T D_0[(y^k - y^{k+1}) - (y^{k-1} - y^k)] \\
= (y^k - y^{k+1})^T (\tau D - (1 - \tau)\beta B^TB) [(y^k - y^{k+1}) - (y^{k-1} - y^k)] \\
\geq \tau \|y^k - y^{k+1}\|_D^2 - (1 - \tau)\beta \|B(y^k - y^{k+1})\|^2 - \frac{\tau}{2} \|y^k - y^{k+1}\|_D^2 \\
- \frac{1}{2} - \tau \|B(y^k - y^{k+1})\|^2 - \frac{1 - \tau}{2} \beta \|B(y^{k-1} - y^k)\|^2 \\
= \frac{\tau}{2} \|y^k - y^{k+1}\|_D^2 - \|y^k - y^{k+1}\|_D^2 - \frac{3(1 - \tau)}{2} \beta \|B(y^k - y^{k+1})\|^2 \\
- \frac{1 - \tau}{2} \beta \|B(y^{k-1} - y^k)\|^2.
\]

Substituting the above inequality into (3.30), we obtain the assertion (3.23) immediately. This completes the proof.

Applying the Cauchy-Schwarz inequality, we can easily derive another evaluation for the crossing term in the right-hand side of (3.20) in the following lemma, whose proof is similar to that in [22, Lemma 4.4].

**Lemma 3.8.** For given \(v^k = (y^k, \lambda^k)\), let \(w^{k+1}\) be generated by IPG-ADMM (3.1) and \(\tilde{w}^k\) be defined by (3.5). Then, for a constant \(\mu > \frac{1}{4}\) and any \(\delta \in (0, \frac{\mu-1}{4\mu})\), we have

\[
(y^k - y^{k+1})^T B^T(Ax^{k+1} + By^{k+1} - b) \\
\geq - \left(\mu \delta + \frac{1}{4}\right) \|B(y^k - y^{k+1})\|^2 - (1 - \delta) \|Ax^{k+1} + By^{k+1} - b\|^2. \tag{3.31}
\]

Based on the previous lemmas, we obtain a lower bound of the term \((v^k - \tilde{v}^k)^T G(v^k - \tilde{v}^k)\) summarized in the following.
Lemma 3.9. For given \( v^k \rangle (y^k, \lambda^k) \), let \( w^{k+1} \) be generated by IPG-ADMM (3.1) and \( \tilde{w}^k \) be defined by (3.5). Then, for \( \delta_0 = \frac{(3-r)(4r-r-3)}{2(1-r)(5+r)} \), we have

\[
(v^k - \tilde{v}^k)^T G(v^k - \tilde{v}^k) \geq \frac{1-r}{1+r} \left[ \frac{\tau}{2} y^k - y^{k+1} \right]_D^2 + \frac{1-\tau}{2} \beta \| B(y^k - y^{k+1}) \|^2 + \frac{1-r}{1+r} \left[ \frac{\tau}{2} y^{k-1} - y^k \right]_D^2 + \frac{1-\tau}{2} \beta \| B(y^{k-1} - y^k) \|^2 + \tau \| y^k - y^{k+1} \|^2_D + (1-r) \delta_0 \beta \| B(y^k - y^{k+1}) \|^2 + \| A x^{k+1} + B y^{k+1} - b \|^2 .
\] (3.32)

Proof. Since \( \tau \in \left( \frac{3-r}{4}, 1 \right) \) and \( r \in (-1, 1) \), we can take \( \mu = \frac{3-r}{2+2r} \) in Lemma 3.8. It follows that \( \mu > \frac{1}{4} \) and

\[
\delta_0 = \frac{(3-r)(4r-r-3)}{2(1-r)(5+r)} \in \left( 0, \frac{4\mu - 1}{4\mu} \right).
\]

Then, adding the two inequalities (3.23) and (3.31) with \( \delta = \delta_0 \), we get

\[
2(y^k - y^{k+1})^T B^T(A x^{k+1} + B y^{k+1} - b) \geq \frac{\tau}{2(1+r)} \left[ \| y^k - y^{k+1} \|^2_D - \| y^{k-1} - y^k \|^2_D \right] + \frac{1-r}{2(1+r)} \left[ \| B(y^k - y^{k+1}) \|^2 - \| B(y^{k-1} - y^k) \|^2 \right] - \left( \frac{2(1-r) + r}{1+r} + \mu \delta_0 + \frac{1}{4} \right) \| B(y^k - y^{k+1}) \|^2 - (1-\delta_0) \| A x^{k+1} + B y^{k+1} - b \|^2 .
\]

Substituting the above inequality into (3.20), with some manipulations, we have

\[
(v^k - \tilde{v}^k)^T G(v^k - \tilde{v}^k) \geq \tau \| y^k - y^{k+1} \|^2_D + \frac{\tau(1-r)}{2(1+r)} (\| y^k - y^{k+1} \|^2_D - \| y^{k-1} - y^k \|^2_D) + \frac{(1-r)(1-r)}{2(1+r)} \beta (\| B(y^k - y^{k+1}) \|^2 - \| B(y^{k-1} - y^k) \|^2) + (1-r) \delta_0 \beta (\| B(y^k - y^{k+1}) \|^2 + \| A x^{k+1} + B y^{k+1} - b \|^2).
\]

It follows that the assertion (3.32) holds immediately. This completes the proof.

4. Convergence analysis. In this section, we analyze the global convergence and convergence rate for IPG-ADMM (3.1).

4.1. Global convergence. The following corollaries are obtained directly from Lemma 3.4, Lemma 3.9 and Theorem 3.5.
Corollary 4.1. For given \( v^k = (y^k, \lambda^k) \), let \( w^{k+1} \) be generated by IPG-ADMM (3.1) and \( \tilde{w}^k \) be defined by (3.5). Then, for \( \delta_0 = \frac{(3-r)(4r-3)}{2(1-r)(5+r)} \), we have
\[
\theta(u) - \theta(\tilde{u}^k) + (w - \tilde{w}^k)^T F(w) \\
\geq \frac{1}{2} \left[ \|v - v^{k+1}\|_2^2 + \frac{1-r}{1+r} \left( \frac{\tau}{2} \|y^k - y^{k+1}\|_D^2 + \frac{1-\tau}{2} \beta \|B(y^k - y^{k+1})\|^2 \right) \right] \\
- \frac{1}{2} \left[ \|v - v^k\|_H^2 + \frac{1-r}{1+r} \left( \frac{\tau}{2} \|y^k - y^k\|_D^2 + \frac{1-\tau}{2} \beta \|B(y^k - y^k)\|^2 \right) \right] \\
+ \frac{1-r}{2} \delta_0 \left( \|B(y^k - y^{k+1})\|_2^2 + \|A x^{k+1} + B y^{k+1} - b\|^2 \right) \\
+ \frac{\tau}{2} \|y^k - y^{k+1}\|_D^2. \quad (4.1)
\]

Corollary 4.2. For given \( v^k = (y^k, \lambda^k) \), let \( w^{k+1} \) be generated by IPG-ADMM (3.1) and \( \tilde{w}^k \) be defined by (3.5). Then, for \( \delta_0 = \frac{(3-r)(4r-3)}{2(1-r)(5+r)} \), we have
\[
\|v^{k+1} - v^*\|_H^2 + \frac{1-r}{1+r} \left( \frac{\tau}{2} \|y^k - y^{k+1}\|_D^2 + \frac{1-\tau}{2} \beta \|B(y^k - y^{k+1})\|^2 \right) \\
\leq \|v^k - v^*\|_H^2 + \frac{1-r}{1+r} \left( \frac{\tau}{2} \|y^k - y^k\|_D^2 + \frac{1-\tau}{2} \beta \|B(y^k - y^k)\|^2 \right) \\
- (1-r) \delta_0 \beta \left( \|B(y^k - y^{k+1})\|_2^2 + \|A x^{k+1} + B y^{k+1} - b\|^2 \right) \\
- \tau \|y^k - y^{k+1}\|_D^2. \quad (4.2)
\]

Now we present the convergence result in the following theorem.

Theorem 4.3. For given \( v^k = (y^k, \lambda^k) \), let \( w^{k+1} \) be generated by IPG-ADMM (3.1) and \( \tilde{w}^k \) be defined by (3.5). Then the sequence \( \{v^k\} \) converges to \( v^\infty \in \mathcal{V}^* \).

Proof. For an arbitrary fixed \( v^* \in \mathcal{V}^* \), it follows from the (4.2) and (3.11) that
\[
\|v^k - v^*\|_H^2 + \left( \frac{\tau}{2} \|y^k - y^k\|_D^2 + \frac{1-\tau}{2} \beta \|B(y^k - y^k)\|^2 \right) \\
\leq \|v^1 - v^*\|_H^2 + \left( \frac{\tau}{2} \|y^0 - y^1\|_D^2 + \frac{1-\tau}{2} \beta \|B(y^0 - y^1)\|^2 \right), \quad \forall k \geq 1,
\]
and thus the sequence \( \{v^k\} \) is bounded. It follows from (3.9) that \( \{\tilde{v}^k\} \) is also bounded. Now, we rewrite (4.2) as
\[
\|v^k - v^*\|_H^2 + \left( \frac{\tau}{2} \|y^k - y^{k+1}\|_D^2 + \frac{1-\tau}{2} \|B(y^k - y^{k+1})\|^2 \right) \\
\leq \left[ \|v^k - v^*\|_H^2 + \left( \frac{\tau}{2} \|y^k - y^k\|_D^2 + \frac{1-\tau}{2} \beta \|B(y^k - y^k)\|^2 \right) \right] \\
- \left[ \|v^{k+1} - v^*\|_H^2 + \left( \frac{\tau}{2} \|y^k - y^{k+1}\|_D^2 + \frac{1-\tau}{2} \beta \|B(y^k - y^{k+1})\|^2 \right) \right]. \quad (4.3)
\]

Summarizing the inequality (4.3) over \( k = 1, 2, 3, \ldots \), we obtain
\[
\sum_{k=1}^{\infty} \left( \|y^k - y^{k+1}\|_D^2 + (1-r) \delta_0 \beta \left( \|B(y^k - y^{k+1})\|_2^2 + \|A x^{k+1} + B y^{k+1} - b\|^2 \right) \right) \\
\leq \|v^1 - v^*\|_H^2 + \left( \frac{\tau}{2} \|y^0 - y^1\|_D^2 + \frac{1-\tau}{2} \beta \|B(y^0 - y^1)\|^2 \right),
\]
Because $D$ is positive definite, $r \in (-1,1)$ and $\delta_0 > 0$, it follows from the above inequality that
\[
\lim_{k \to \infty} \|y^k - y^{k+1}\|^2 = 0, \quad \text{and} \quad \lim_{k \to \infty} \|Ax^{k+1} + By^{k+1} - b\|^2 = 0.
\]
Applying the above relations to \((3.1b)\) and \((3.1d)\), we obtain
\[
\lim_{k \to \infty} \|\lambda^k - \lambda^{k+1}\|^2 = \lim_{k \to \infty} \|r \beta (Ax^{k+1} + By^k - b) + \beta (Ax^{k+1} + By^{k+1} - b)\|^2
\]
\[
= \lim_{k \to \infty} \|(r + 1) \beta (Ax^{k+1} + By^{k+1} - b) + r \beta (y^k - y^{k+1})\|^2 = 0.
\]
Thus, we have
\[
\lim_{k \to \infty} \|v^k - v^{k+1}\|^2 = 0. \tag{4.4}
\]
For an arbitrarily fixed $v^* \in \mathcal{V}^*$ and $\forall k \geq 1$, it follows that
\[
\frac{1}{\tau} \leq \|v^k - v^*\|^2_H + \frac{1}{1 + r} \left( \frac{\tau}{2} \|y^{k-1} - y^k\|^2_D + \frac{1 - \tau}{2} \beta \|B(y^{k-1} - y^k\|^2\right)
\]
\[
\leq \|v^1 - v^*\|^2_H + \frac{1 - r}{1 + r} \left( \frac{\tau}{2} \|y^0 - y^1\|^2_D + \frac{1 - \tau}{2} \beta \|B(y^0 - y^1\|^2\right). \tag{4.5}
\]
Let $v^\infty$ be a cluster point of $\{v^k\}$. Then $\{\hat{v}^k\}$ has a subsequence $\{\tilde{v}^k\}$ converging to $v^\infty$. Let $x^\infty$ be the vector accompanied with $(y^\infty, \lambda^\infty) \in \mathcal{V}$. Recalling the matrix $B$ is assumed to be full column rank, it follows from \((3.16)\) that
\[
w^\infty \in \Omega, \quad \theta(u) - \theta(u^\infty) + (w - w^\infty)^T F(w^\infty) \geq 0, \quad \forall w \in \Omega,
\]
which means $w^\infty$ is a solution point of \((2.3)\) and its essential part $v^\infty \in \mathcal{V}^*$. Since $v^\infty \in \mathcal{V}^*$, it follows from \((4.5)\) that
\[
\|v^{k+1} - v^\infty\|^2_H \leq \|v^k - v^\infty\|^2_H + \frac{1 - r}{1 + r} \left( \frac{\tau}{2} \|y^{k-1} - y^k\|^2_D + \frac{1 - \tau}{2} \beta \|B(y^{k-1} - y^k\|^2\right).
\]
Notice that $v^\infty$ is also the limit point of $\{v^k\}$. Together with \((4.4)\), it is impossible that the sequence $\{v^k\}$ has more than one cluster point. Thus $\{v^k\}$ converges to $v^\infty$ and the theorem is proved. \hfill \Box

4.2. **Convergence rate.** According to \((2.3)\), if we find a $\tilde{w}$ which satisfies
\[
\tilde{w} \in \Omega, \quad \theta(u) - \theta(\tilde{u}) + (w - \tilde{w})^T F(\tilde{w}) \geq 0, \quad \forall w \in \Omega,
\]
then $\tilde{w}$ is a solution of \((2.3)\). By using \((3.15)\), the solution $\tilde{w}$ can be also stated as
\[
\tilde{w} \in \Omega, \quad \theta(u) - \theta(\tilde{u}) + (w - \tilde{w})^T F(w) \geq 0, \quad \forall w \in \Omega.
\]
We use the latter equality to measure the approximation of \((2.3)\), which means that for given $\epsilon > 0$, $\tilde{w} \in \Omega$ is an $\epsilon$-approximate solution of VI$(\Omega, F, \theta)$ if
\[
\tilde{w} \in \Omega, \quad \theta(u) - \theta(\tilde{u}) + (w - \tilde{w})^T F(w) \geq -\epsilon, \quad \forall w \in \mathcal{D}(\tilde{w}),
\]
where
\[
\mathcal{D}(\tilde{w}) = \{ w \in \Omega \mid \|w - \tilde{w}\| \leq 1 \}.
\]
We will show that for given $\epsilon > 0$, after $t$ iterations, it can offer a $\tilde{w} \in \Omega$, such that
\[
\tilde{w} \in \Omega \quad \text{and} \quad \sup_{w \in \mathcal{D}(\tilde{w})} \{ \theta(\tilde{u}) - \theta(u) + (\tilde{w} - w)^T F(w) \} \leq \epsilon. \tag{4.6}
\]
Corollary 4.1 is the base for the convergence rate proof.

**Theorem 4.4.** For given \( v^k = (y^k, \lambda^k) \), let \( w^{k+1} \) be generated by IPG-ADMM (3.1) and \( \tilde{w}^k \) be defined by (3.5). Then for any integer \( t \), we have \( \forall w \in \Omega \),

\[
\theta(\tilde{u}_t) - \theta(u) + (\tilde{w}_t - w)^T F(w) \leq \frac{1}{2t} \left[ \|v - v^1\|^2_H + \frac{1 - r}{1 + r} \left( \frac{\tau}{2} \|y^0 - y^1\|^2_D + \frac{1 - \tau}{2} \|\beta B(y^0 - y^1)\|^2 \right) \right] \tag{4.7a}
\]

where

\[
\tilde{w}_t = \frac{1}{t} \sum_{k=1}^t \tilde{w}^k. \tag{4.7b}
\]

**Proof.** First, it follows from (4.1) that

\[
\theta(u) - \theta(\tilde{u}^k) + (w - \tilde{w}^k)^T F(w) \geq \frac{1}{2} \left[ \|v - v^{k+1}\|^2_H + \frac{1 - r}{1 + r} \left( \frac{\tau}{2} \|y^k - y^{k+1}\|^2_D + \frac{1 - \tau}{2} \|\beta B(y^k - y^{k+1})\|^2 \right) \right] \tag{4.8}
\]

Summing the inequality (4.8) over \( k = 1, 2, \ldots, t \), we obtain

\[
\sum_{k=1}^t \theta(\tilde{u}^k) - t \theta(u) + (\sum_{k=1}^t \tilde{w}^k - tw)^T F(w) \leq \frac{1}{2} \left[ \|v - v^1\|^2_H + \frac{1 - r}{1 + r} \left( \frac{\tau}{2} \|y^0 - y^1\|^2_D + \frac{1 - \tau}{2} \|\beta B(y^0 - y^1)\|^2 \right) \right],
\]

and consequently

\[
\frac{1}{t} \sum_{k=1}^t \theta(\tilde{u}^k) - \theta(u) + (\tilde{w}_t^k - w)^T F(w) \leq \frac{1}{2t} \left[ \|v - v^1\|^2_H + \frac{1 - r}{1 + r} \left( \frac{\tau}{2} \|y^0 - y^1\|^2_D + \frac{1 - \tau}{2} \|\beta B(y^0 - y^1)\|^2 \right) \right]. \tag{4.9}
\]

It follows from the definition of \( \tilde{w}_t \) in (4.7b) that

\[
\tilde{u}_t = \frac{1}{t} \sum_{k=1}^t \tilde{u}^k.
\]

Since \( \theta(u) \) is convex, it follows that

\[
\theta(\tilde{u}_t) \leq \frac{1}{t} \sum_{k=1}^t \theta(\tilde{u}^k).
\]

Substituting it into (4.9), the assertion (4.7a) follows directly. \( \square \)
Thus, \(3^{+}\) is not necessarily convergent for any \(\tau\). That is, the recursion (5.2) can be specified as:

\[
d = \sup \left\{ \|v - v^*\|_H^2 + 1 - \frac{r}{1 + r} \left( \frac{\tau}{2} \|y^0 - y^1\|_D^2 + \frac{1}{2} \|\beta B(y^0 - y^1)\|^2 \right) \right\},
\]

where \(v^0 = (y^0, \lambda^0)\) and \(v^1\) are the initial point and the first computed iterate, respectively. Then, after \(t\) iterations of the indefinite proximal generalized ADMM (3.1), the point \(\hat{w}_t \in \Omega\) defined in (4.7b) satisfies

\[
\hat{w} \in \Omega \quad \text{and} \quad \sup_{w \in D(\hat{w})} \{ \theta(u) - \theta(\hat{u}) + (\hat{w} - w)^T F(w) \} \leq \frac{d}{2t},
\]

which means \(\hat{w}_t\) is an approximate solution of VI(\(\Omega, F, \theta\)) with the accuracy \(O(1/t)\) (recall (4.6)). That is, the convergence rate \(O(1/t)\) of the IPG-ADMM (3.1) is established in an ergodic sense.

5. Optimality of \(\tau\). In Section 4, we have showed that the IPG-ADMM (3.1) is convergent when \(\tau \in \left(\frac{2 + r}{1 + r}, 1\right)\). In this section, we show that the IPG-ADMM (3.1) is not necessarily convergent for any \(\tau \in (0, \frac{2 + r}{1 + r})\) by a simple linear programming. Thus, \(\frac{2 + r}{1 + r}\) is the optimal lower bound with \(r \in (-1, 1)\) for the proximal parameter \(\tau\) of the IPG-ADMM (3.1).

Let us consider the following extremely simple linear programming in [22]:

\[
\min \{0 \cdot x + 0 \cdot y | 0 \cdot x + y = 0, x \in \{0\}, y \in \mathbb{R}\},
\]

which is a special case of the model (1.1). Without loss of generality, we set \(\beta = 1\) and hence the augmented Lagrangian function of (5.1) is

\[
L_1(x, y, \lambda) = -\lambda^T y + \frac{1}{2} y^2.
\]

The scheme of the IPG-ADMM (3.1) for (5.1) is

\[
\begin{cases}
  x^{k+1} = \arg \min \{ L_1(x, y^k, \lambda^k) | x \in \{0\} \}, \\
  \lambda^{k+\frac{1}{2}} = \lambda^k - ry^k, \\
  y^{k+1} = \arg \min \{ -y^T \lambda^{k+\frac{1}{2}} + \frac{1}{2} y^2 + \frac{1}{2} \|y - y^k\|^2_{D_0} | y \in \mathbb{R}\}, \\
  \lambda^{k+1} = \lambda^{k+\frac{1}{2}} - y^{k+1}.
\end{cases}
\]

(5.2)

Since \(\beta = 1\) and \(B^TB = 1\), it follows from (3.2) and (3.3) that

\[
D_0 = \tau \rho - 1 \quad \text{and} \quad D = \rho - 1 \quad \text{with} \quad \rho > 1.
\]

Thus the recursion (5.2) can be specified as

\[
\begin{cases}
  x^{k+1} = 0, \\
  \lambda^{k+\frac{1}{2}} = \lambda^k - ry^k, \\
 -\lambda^{k+\frac{1}{2}} + y^{k+1} + (\tau \rho - 1)(y^{k+1} - y^k) = 0, \\
  \lambda^{k+1} = \lambda^{k+\frac{1}{2}} - y^{k+1}.
\end{cases}
\]

(5.3)

For any \(k > 0\), we have \(x^k = 0\). Thus, we only need to study the essential sequence \(v^k = (y^k, \lambda^k)\). For any given \(\tau \in (0, \frac{2 + r}{1 + r})\), there exists \(\rho > 1\) such that \(\tau \rho \leq \frac{2 + r}{1 + r}\). We set \(\alpha = \tau \rho\) and the recursion (5.3) can be written as

\[
\begin{cases}
  y^{k+1} = \frac{\alpha - 1 - r}{\alpha} y^k + \frac{1}{\alpha} \lambda^k, \\
  \lambda^{k+1} = \frac{(r + 1)(1 - \alpha)}{\alpha} y^k + \frac{\alpha - 1}{\alpha} \lambda^k.
\end{cases}
\]

(5.4)
Its compact form is
\[ v^{k+1} = P(\alpha)v^k \quad \text{with} \quad P(\alpha) = \frac{1}{\alpha} \begin{pmatrix} \alpha - 1 - r & 1 \\ (r+1)(1-\alpha) & \alpha - 1 \end{pmatrix}. \] (5.5)

Let \( f_1(\alpha) \) and \( f_2(\alpha) \) be the two eigenvalues of matrix \( P(\alpha) \). Then, we have
\[ f_1(\alpha) = \frac{(2\alpha - 2 - r) + \sqrt{(r+2)^2 - 4\alpha(r+1)}}{2\alpha}, \]
and
\[ f_2(\alpha) = \frac{(2\alpha - 2 - r) - \sqrt{(r+2)^2 - 4\alpha(r+1)}}{2\alpha}. \]

It is easy to estimate that \( f_2(\frac{3+r}{4}) = -1 \) and
\[ f'_2(\alpha) = \frac{1}{2\alpha^2} \left( 2 + r + \frac{(r+2)^2 - 2\alpha(r+1)}{(r+2)^2 - 4\alpha(r+1)} \right) > 0, \quad \forall \alpha \in (0, \frac{3+r}{4}). \]

Thus, we have
\[ f_2(\alpha) = \frac{(2\alpha - 2 - r) - \sqrt{(r+2)^2 - 4\alpha(r+1)}}{2\alpha} < -1, \quad \forall \alpha \in (0, \frac{3+r}{4}). \]

That is to say, for any \( \alpha \in (0, \frac{3+r}{4}) \), the matrix \( P(\alpha) \) (5.5) has the eigenvalue which is less than \(-1\). Hence, the recursion (5.3) is not necessarily convergent for any \( \tau \in (0, \frac{3+r}{4}) \).

6. **Numerical results.** In this section, we verify the theoretical assertions analyzed in previous sections by some numerical experiments. We apply the proposed method to solve the least absolute shrinkage and selection operator (LASSO) and the total variation (TV) denoising problems. We shall verify the following assertions.

1. The proposed IPG-ADMM (3.1) converges quickly for a wide range of applications. The theoretical significance of the underdetermined relaxation parameter \( r \) is thus verified.
2. For the proposed IPG-ADMM (3.1), the convergence speed is relative to the parameter \( r \).
3. The proposed IPG-ADMM (3.1) is faster than the PID-SADMM in [14] and PG-ADMM (1.4) when we fix a value of \( r \).

We should point out that our proposed method may be not the best method for solving these models. We use merely these models to illustrate the efficiency and stability for the proposed method. All codes were written by MATLAB R2013a and all the numerical experiments were conducted on a personal computer with a 3.6GHz i7 processor and a 4GB memory.

6.1. **LASSO.** The LASSO model proposed in [35] can be characterized as
\[ \min \left\{ \rho \|y\|_1 + \frac{1}{2} \|By - b\|_2^2 \mid y \in \mathbb{R}^m \right\}. \] (6.1)

where \( b \in \mathbb{R}^n \) is the response vector, \( B \in \mathbb{R}^{n \times m} \) is the design matrix, \( n \) is the number of data points, \( m \) is the number of features, \( \rho > 0 \) is a regularization parameter and \( \|y\|_1 := \sum_{i=1}^m |y_i| \). The LASSO model provides a sparse estimation of \( y \) when there are more features than data points (i.e., \( m > n \)).
Now, by introducing an auxiliary variable $x \in \mathbb{R}^n$, the model (6.1) can be reformulated as
\[
\min \left\{ \frac{1}{2} \|x\|_2^2 + \varrho \|y\|_1 \mid x - By + b = 0, x \in \mathbb{R}^n, y \in \mathbb{R}^m \right\},
\]
which is a special case of (1.1). Thus PG-ADMM, PID-SADMM and IPG-ADMM can be applied to solve (6.2). In order to obtain the solution of $y$-subproblem, we use the soft-thresholding operator defined as
\[
(S_\kappa(a))_i = (1 - \kappa/|a_i|)_+\cdot a_i, \quad i = 1, \ldots, m,
\]
where $\kappa > 0$ and $a \in \mathbb{R}^m$(see [2]).

Now we specify the setting for the LASSO model to be tested. We first choose $B_{ij} \sim \mathcal{N}(0,1)$ and then normalize the columns. We generate a random sparse vector in $\mathbb{R}^m$ with the density 0.02 as $y$, the noise vector $\epsilon \sim \mathcal{N}(0, 10^{-3}I)$ and the vector $b = By + \epsilon$, the regularization parameter is set as $\varrho = 0.1\|B^Tb\|_\infty$. Here, we use the residuals of $y$-subproblem and $\lambda$-subproblem to construct the stopping criteria which is described as follows:
\[
tol := \max \left\{ \|r \rho(y^k - \tilde{y}^k) - rB^T(\lambda^k - \tilde{\lambda}^k)\|_\infty, \|B(y^k - \tilde{y}^k) + \frac{1}{\beta}(\lambda^k - \tilde{\lambda}^k)\|_\infty \right\} \leq 10^{-3}.
\]

Now we specify the choices of parameters to implement these algorithms. First, we choose $\beta = 1$ and $\rho = 0.01$ for the tested algorithms. Moreover, the initial points are $y^0 = 0_{m \times 1}$ and $\lambda^0 = 0_{n \times 1}$. In order to investigate the stability and efficiency of our algorithm, we test 8 groups of problems with different $n$ and $m$. For each group, we set $r = 0.3$ and $r = -0.3$ respectively and test 10 times. Since small values of $\tau$ are preferred in practical computation, we set $\tau = \frac{\beta + r}{1 + 10^{-3}}$ in the IPG-ADMM and $\tau = \frac{\beta + r + 4}{r + 10^{-3}}$ in the PID-SADMM. In Table 1, we report the average performances including the number of iterations (Iter.) and the CPU time (CPU(s)). We also test the sensitivity of $r$ of three methods for the LASSO model (6.1). We first fix $n = 400, m = 1200, \beta = 1$ and choose different values of $r$ in the interval $[-0.95, 0.95]$. More specifically, we choose $r = \{-0.95, 0.90, 0.85, \ldots, 0.85, 0.90, 0.95\}$. Then, we set the maximal number of iteration as 200. The computing time and number of iterations required by the three methods are reported for each choice of $r$ and then we plot them in Figure 1.

| $n$ | $m$ | PG-ADMM Iter. CPU(s) | PG-ADMM Iter. CPU(s) | PG-ADMM Iter. CPU(s) | PG-ADMM Iter. CPU(s) | PG-ADMM Iter. CPU(s) |
|-----|-----|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|
| 200 | 500 | 68.0 0.34 | 55.1 0.05 | 54.0 0.04 | 68.0 0.04 | 45.0 0.03 |
| 300 | 800 | 68.0 0.35 | 57.2 0.29 | 55.7 0.28 | 69.0 0.35 | 53.3 0.27 |
| 300 | 1000 | 69.1 0.66 | 76.9 0.55 | 75.0 0.54 | 92.0 0.66 | 71.0 0.51 |
| 500 | 1500 | 88.1 1.39 | 67.3 1.49 | 65.9 1.46 | 81.3 1.80 | 62.8 1.39 |
| 500 | 2000 | 108.0 4.28 | 90.7 1.82 | 88.6 2.77 | 108.3 3.33 | 83.6 2.60 |
| 800 | 2500 | 84.5 0.90 | 72.1 0.56 | 70.5 0.44 | 87.0 0.57 | 67.0 0.42 |
| 1000 | 3000 | 79.0 1.12 | 66.3 0.12 | 64.8 0.17 | 80.2 1.34 | 61.9 0.84 |
| 1500 | 5000 | 92.8 2.22 | 77.9 1.66 | 76.2 1.24 | 93.9 2.23 | 72.3 1.37 |

According to the results presented in Table 1, we see that IPG-ADMM can solve the problems efficiently. Moreover, the IPG-ADMM is stable and faster than the
other methods for slightly larger scale problems in the experiment. From Figure 1, it is obvious to see that the factor $r$ functions well for a wide range of values. In particular, based on our experiments, some aggressive values (e.g., $[-0.6, -0.4]$) are preferred for the LASSO model.

6.2. Total variation denoising model. In this subsection, we test the IPG-ADMM on the total variation (TV) denoising problem in [2, 32]:

$$\min \left\{ \frac{1}{2} \|y - b\|_2^2 + \eta \|Dy\|_1 \mid y \in \mathbb{R}^m \right\},$$  

(6.4)

where $D : \mathbb{R}^n \to \mathbb{R}^n$ is the finite-difference operator in the vertical direction. By introducing a new variable $x$, we can reformulate (6.4) as

$$\min \left\{ \eta \|x\|_1 + \frac{1}{2} \|y - b\|_2^2 \mid x - Dy = 0, x \in \mathbb{R}^n, y \in \mathbb{R}^n \right\},$$  

(6.5)

which is also a special case of (1.1). Then the PG-ADMM, PID-SADMM and IPG-ADMM can be applied to (6.5).

Now we specify the setting for the TV model (6.4) to be tested. For a given dimension $n \times n$, We generate the data randomly as follows [2] for $j = 1:3$

```matlab
for j = 1:3
    idx = randsample(n, 1);
    k = randsample(1:10, 1);
    y(ceil(idx/2):idx) = k*y(ceil(idx/2):idx);
end
```

```matlab
b = y + randn(n, 1);
e = ones(n, 1);
D = spdiags([e-e], 0 : 1, n, n);
```

The regularization parameter is set as $\eta = 5$. Here, we still use the stopping criteria (6.3). Now we specify the choices of parameters to implement these algorithms. First, we choose $\beta = 5$ and $\rho = \beta \|D^T D\| + 0.01$ for the tested algorithms. Moreover, the initial points are $y^0 = 0_{n \times 1}$ and $\lambda^0 = 0_{n \times 1}$. In order to investigate the stability and efficiency of our algorithm, we test 8 groups of problems with different $n$. For each group, we set $r = 0.3$ and $r = -0.3$ respectively and test 10 times. We also set $\tau = \frac{\tau - 1}{4} + 0.01$ in the IPG-ADMM and $\tau = \frac{\tau^2 - \tau + 1}{4\tau - 2\tau + 5}$ in the PID-SADMM.
Table 2. Numerical results for TV denoising model.

| n       | PG-ADMM | PID-SADMM | IPG-ADMM | PG-ADMM | PID-SADMM | IPG-ADMM |
|---------|---------|-----------|----------|---------|-----------|----------|
|         | Iter.   | CPU(s)    | Iter.    | CPU(s)  | Iter.     | CPU(s)   | Iter.    | CPU(s)  | Iter.     | CPU(s)   |
| 500     | 278.0   | 0.03      | 260.7    | 0.03    | 258.7     | 0.03     | 401.5   | 0.05    | 356.6     | 0.04     |
| 1000    | 325.9   | 0.06      | 297.4    | 0.05    | 294.6     | 0.05     | 464.8   | 0.08    | 422.0     | 0.08     |
| 2000    | 414.9   | 0.12      | 380.8    | 0.11    | 376.7     | 0.11     | 585.3   | 0.17    | 533.2     | 0.16     |
| 3000    | 449.5   | 0.20      | 423.9    | 0.19    | 418.9     | 0.19     | 683.8   | 0.31    | 602.7     | 0.27     |
| 5000    | 488.7   | 0.33      | 456.0    | 0.30    | 452.3     | 0.30     | 730.0   | 0.48    | 662.7     | 0.44     |
| 6000    | 488.1   | 0.38      | 450.0    | 0.35    | 452.1     | 0.35     | 720.7   | 0.56    | 642.0     | 0.50     |
| 8000    | 598.3   | 0.59      | 558.2    | 0.54    | 553.9     | 0.54     | 869.5   | 0.85    | 774.7     | 0.75     |
| 10000   | 699.6   | 0.72      | 561.9    | 0.66    | 556.7     | 0.66     | 877.0   | 1.03    | 791.0     | 0.93     |

(a) $r$'s effect on the number of iterations.

(b) $r$'s effect on the execution.

Figure 2. Sensitivity test on the factor $r$ when $\beta = 5$.

In Table 2, we report the average performances including the number of iterations (Iter.) and the CPU time (CPU(s)). We also test the sensitivity of $r$ of three methods for the TV denoising model (6.4). We fix $n = 2000$, $\beta = 5$ and choose different values of $r$ in the interval $[-0.95, 0.95]$ as that in last subsection. Then, we set the maximal number of iteration is 1000. The computing time and number of iterations required by the three methods are reported for each choice of $r$ and then we plot them in Figure 2.

Table 2 shows that the IPG-ADMM is more efficient than the PG-ADMM and PID-SADMM for the TV denoising model (6.4). Moreover, the speed of algorithms are revelent to the dimension of the variables. From Figure 2, the IPG-ADMM is stable in our test, and faster than the PG-ADMM and PID-SADMM for slightly larger problems.

7. Conclusions. In this paper, we proposed a new indefinite proximal generalized ADMM, which combined the linearized generalized ADMM with the indefinite proximal term. We analyzed the convergence and the worst-case $O(1/t)$ convergence rate of the proposed method by specifying a better lower bound for the proximal parameter. Moreover, by showing a special example of linear programming, we illustrated that the proximal parameter of the proposed method is optimal. We also gave some primal numerical experiments to demonstrate the efficiency and the advantage of the proposed method.
Acknowledgments. The authors are deeply grateful to Professor Bingsheng He for his help during the completion of this work.
