MYB transcription factors (TFs) mediate plant responses and defenses to biotic and abiotic stresses. The effects of overexpression of MYB37, an R2R3 MYB subgroup 14 transcription factors in Arabidopsis thaliana, on chlorophyll content, chlorophyll fluorescence parameters, reactive oxygen species (ROS) metabolism, and the contents of osmotic regulatory substances were studied under 100 mM NaCl stress. Compared with the wild type (Col-0), MYB37 overexpression significantly alleviated the salt stress symptoms in A. thaliana plants. Chlorophyll a (Chl a) and chlorophyll b (Chl b) contents were significantly decreased in OE-1 and OE-2 than in Col-0. Particularly, the Chl a/b ratio was also higher in OE-1 and OE-2 than in Col-0 under NaCl stress. However, MYB37 overexpression alleviated the degradation of chlorophyll, especially Chl a. Salt stress inhibited the activities of PSII and PSI in Arabidopsis leaves, but did not affect the activity of PSII electron donor side oxygen-evolving complex (OEC). MYB37 overexpression increased photosynthesis in Arabidopsis by increasing PSII and PSI activities. MYB37 overexpression also promoted the transfer of electrons from Q_α to Q_β on the PSII receptor side of Arabidopsis under NaCl stress. Additionally, MYB37 overexpression increased Y(II) and Y(NPQ) of Arabidopsis under NaCl stress and decreased Y(NO). These results indicate that MYB37 overexpression increases PSII activity and regulates the proportion of energy dissipation in Arabidopsis leaves under NaCl stress, thus decreasing the proportion of inactivated reaction centers. Salt stress causes excess electrons and energy in the photosynthetic electron transport chain of Arabidopsis leaves, resulting in the release of reactive oxygen species (ROS), such as superoxide anion and hydrogen peroxide, leading to oxidative damage. Nevertheless, MYB37 overexpression reduced accumulation of malondialdehyde in Arabidopsis leaves under NaCl stress and alleviated the degree of membrane lipid peroxidation caused by ROS. Salt stress also enhanced the accumulation of soluble sugar (SS) and proline (Pro) in Arabidopsis leaves, thus reducing salt stress damage to plants. Salt stress also degraded...
INTRODUCTION

A biotic stress, especially salt stress, has gradually become the primary factor affecting the survival and distribution of plants due to the change in global climate conditions (Shaheen et al., 2013). Salt stress mainly affects plants in three aspects: (I) Excessive salt in the soil produces osmotic stress. As a result, the water potential becomes lower in soil than in plant root cells, thus inhibiting water absorption (Rana and Mark, 2008). (II) Gradual accumulation of Na⁺ inhibits the absorption of K⁺ in plants, thus affecting some physiological and biochemical reactions that are dependent on K⁺, including enzymatic reactions, protein synthesis, and photosynthesis. Excessive Na⁺ and Cl⁻ also significantly increase intracellular Ca²⁺, resulting in metabolic disorder and even death (Tsugane et al., 1999). (III) Salt stress causes secondary stresses on plants, including oxidative stress and the inhibition of photosynthesis. Excessive reactive oxygen species (ROS) can produce oxidative stress on plants, and damage DNA, enzymes, and biofilm, thus affecting cell structure and metabolism (Dorothea and Ramanjulu, 2005). For instance, salt stress decreases the stability of thylakoid membranes by increasing the rate of chlorophyll degradation in plants, thus hindering the electron transport chain and energy transport of the photosynthetic system and inhibiting photosynthesis (Zhao et al., 2019; Zhang et al., 2020b). Photosynthesis, particularly the photo-inhibition of photosystem II (PSII) and photosystem I (PSI), is closely related to ROS production (Che et al., 2018). Excessive ROS disturbs the redox balance in cells, leading to oxidative damage (Jithesh et al., 2006). Therefore, excessive accumulation of ROS in plants under salt stress can significantly affect plant biomass (Klaus and Heribert, 2004). The adaptation of plants to abiotic stress is a complex process involving cell adaptation at the molecular, biochemical and physiological levels (Pushp et al., 2015). The transcriptional machinery associated with stress responses maintains the growth, metabolism, and development of plants through an intricate network of transcription factors (TFs; Agarwal et al., 2013).

Related studies have found that TFs play crucial roles in plant signal regulatory networks. TFs receive the perceived signals and regulate the expression of downstream genes. TFs also act as a node to coordinate the interaction between different signaling pathways. TFs provide complex control mechanisms for plants to manage abiotic and biological stresses, thus regulating developmental processes (Mitsuda and Ohme, 2009). Therefore, the functional study of stress response of transcription factors may provide insights into how plants adapt to severe environments at the molecular level. More than 1,600 TFs have been identified in Arabidopsis (Riechmann et al., 2000; Chen et al., 2006). These TFs can help plants rapidly adapt to changing environments by regulating gene transcription (Zhu, 2002; Kazuo et al., 2003; Chinnusamy et al., 2004). The MYB domain TFs are characterized by a conserved MYB domain with about 52 amino acids involved in DNA binding and are present in all eukaryotes (Yu et al., 2016b). The MYB TF family in Arabidopsis contains 200 genes. It is the largest TF family in Arabidopsis, accounting for 9% of all the TFs in this plant (Riechmann et al., 2000; Soren et al., 2013). Many members of the MYB TF family play a role in tolerance to abiotic stress (Li et al., 2015; Zhang et al., 2020c), regulation of nitrogen absorption and utilization (Liu et al., 2022), and defense responses to pathogens (Mengiste et al., 2003; Liu et al., 2013). The MYB proteins are divided into four subfamilies based on the number of adjacent repeats in the MYB domain (R1-MYB, R2R3-MYB, 3R-MYB, and 4R-MYB; Dubos et al., 2010). The R2R3-MYB family is common in plants (Jiang and Rao, 2020; Wu et al., 2022), with about 126 of these TFs found in Arabidopsis (Chen et al., 2006). Many members of the MYB TF family participate in Arabidopsis response to salt stress (Mengiste et al., 2003; Xie et al., 2010; Cui et al., 2013; Xu et al., 2015; Wang et al., 2016). However, only a few studies have assessed how MYB regulates plant photosynthesis and oxidative damage under salt stress. Previous studies have shown that MYB37, R2R3 MYB subgroup 14 TF in Arabidopsis, affects the phenotypic changes of plant hairy roots by mediating plant hormone signaling pathway. MYB37 also positively regulates plant response to abscisic acid (ABA) and drought stress, thus improving the seed setting rate of Arabidopsis (Dubos et al., 2010; Yu et al., 2016a; Zheng et al., 2020). This study evaluated the effects of MYB37 overexpression on chlorophyll content, PSII and PSI functions in light reactions, ROS metabolism, and osmotic regulation in Arabidopsis leaves under salt stress. Therefore, this study may provide new insights into how MYB37 alleviates salt stress and provides a theoretical basis for improving the genes related to stress resistance.

MATERIALS AND METHODS

Experimental Materials

The Arabidopsis seeds were disinfected, then sown on MS solid medium. The seeds were vernalized at 4°C for 2 days and cultured in a greenhouse at 21°C, light intensity of 400 µmol·m⁻²·s⁻¹, photoperiod of 16/8 h (light/dark), and relative
humidity of 60%. Agrobacterium tumefaciens containing the recombinant plasmid p MDC85-35:MYB37-GFP was used to genetically transform wild-type A. thaliana (Col-0) via inflorescence infection. The positive transgenic lines were screened based on their resistance to hygromycin. The transgenic plants were verified using PCR and real-time quantitative reverse transcription PCR (qRT-PCR). Genotypic lines (OE-1 and OE-2) with high expression levels of MYB37 in the third generation (T3) homozygous lines were used as the experimental materials. NaCl (100 mmol L⁻¹) and an equal volume of water were used to irrigate Arabidopsis transgenic lines (OE-1 and OE-2) and Arabidopsis wild type (Col-0) when the seedlings had grown for 4 weeks. A plastic tray was placed under each basin to prevent the loss of salt solution. The solution was poured back into the tray when the matrix was slightly dry. Arabidopsis leaves of each treatment group were randomly sampled on after 7 d irrigation for the following analyses.

Parameter Measurements and Methods

Real-Time PCR Analysis

The 10-day-old seedlings were used to determine the MYB37 transcript levels in the wild-type Col-0 and the plants overexpressing MYB37. Total RNA was extracted from about 100 mg of plant tissue using a Total RNA Rapid Extraction Kit (BioTeke Co., Ltd., Wuxi, China). The total RNA was treated with RNase-free DNaseI (NEB, Ipswich, MA, United States) at 37°C for 1 h to degrade the genomic DNA, then purified using an RNA Purification Kit (BioTeke Co., Ltd.). The total RNA (2 μg) was used to synthesize first-strand cDNA via a Roche Transcriptor First Strand cDNA Synthesis Kit (Roche, Basel, Switzerland) and an oligo (dT18) primer. A Bio-Rad Real-Time System CFX96TM C1000 Thermal Cycler (Bio-Rad, Singapore, Singapore) was used for the analysis. ACTIN2/8 genes were amplified and used as the internal control. The cDNA was amplified using SYBR Premix Ex Taq (TaKaRa, Singapore, Singapore) was used for the analysis. ACTIN2/8: forward primer: GGTAACATTGTGCTCAGTGG; reverse primer: AACGACCTTAATCTTCATGCTGC.

Subcellular Localization of MYB37

The roots of 1-week-old MYB37-overexpressing seedlings (OE-2) were immersed in 2 μg/ml 4’-6-diamidino-2-phenylindole (DAPI) solution for 10–15 min for nucleus labeling. The roots were visualized using fluorescence microscopy (EVOS™ FL Auto; Thermo Fisher Scientific, Waltham, MA, United States).

Determination of the OJIP Curve and 820 nm Light Reflection Curve (MR820)

The leaves of Arabidopsis plants were used for a dark adaptation experiment for 30 min using a dark adaptation clip. The OJIP and 820 nm light reflection curves (MR820) were measured five times using a Hansatech multifunctional plant efficiency instrument (M-PEA; Hansatech Instruments, Ltd., King’s Lynn, United Kingdom) after dark adaptation. The corresponding time points at O, J, I, and P points were 0.01, 2, 30, and 1,000 ms, respectively (represented as F0, FJ, FI, and FP, respectively). Points L and K represent the corresponding points on the curve at 0.15 ms and 0.3 ms, respectively. O-P and O-J were standardized on the OJIP curve. The relative fluorescence intensity (F0) of the O point was set to 0, while the relative fluorescence intensity (FJ) of the P, J and K points was set to 1 as follows: \( V_{O,P} = \frac{(F_L - F_O)}{(F_J - F_O)} \) and \( V_{O,J} = \frac{(F_K - F_O)}{(F_J - F_O)} \), where \( F_O \) represents the relative fluorescence intensity of each time point. The relative variable fluorescence intensities of the K and J points on the standardization curve were expressed as \( V_K \) and \( V_J \) respectively [\( V_K (F_K - F_O) / (F_J - F_O) \) and \( V_J (F_I - F_O) / (F_P - F_O) \)]. A JIP test analysis was conducted as described by Strasser and Strasser (1995). The PSI maximum photochemical efficiency (Fm/Fm′) and photosynthetic performance index were determined based on light absorption (PFA80). The slope of the initial section of MR820 curve (\( \Delta I/I_o \)) where \( I_o \) and \( \Delta I \) represent the maximum value and the difference between the maximum value and the minimum value of the reflected signal in 820 nm light reflection curve, respectively represented the activity of the PSI reaction center (Oukarroum et al., 2018).

Determination of Chlorophyll Content

Fresh leaves without main veins were soaked in a 1:1 solution of acetone and alcohol (v/v) to extract the pigments [Chlorophyll a (Chl a), Chlorophyll b (Chl b), total chlorophyll (Chl a+b) and chlorophyll a/b (Chl a/b)] (Porra, 2002).

Histochemical Staining of Superoxide Anion (O₂⁻) and Hydrogen Peroxide (H₂O₂)

The superoxide anions (O₂⁻) and hydrogen peroxide (H₂O₂) in fresh leaves were stained using nitro blue tetrazolium chloride (NBT) and 3’,3’-diaminobenzidine tetrahydrochloride (DAB), respectively, as described by Mostofa et al. (2015).

Determination of Reactive Oxygen Species (ROS) and Malondialdehyde (MDA) Contents

The rate of production of superoxide anion (O₂⁻) and the content of hydrogen peroxide (H₂O₂) were determined as
described by Zhang et al. (2006) and Alexieva et al. (2001). The content of MDA was determined using thiobarbituric acid (TBA) colorimetry (Ernster et al., 1968).

Determination of Osmotic Regulatory Substances Content

The contents of soluble sugar (SS), soluble protein (SP), and free proline (Pro) were determined using anthrone colorimetry (Bradford, 1976), Coomassie brilliant blue G-250 staining (Bradford, 1976), acid ninhydrin colorimetry (Bates et al., 1973), respectively.

Statistical Analysis

Microsoft Excel 2016 (Redmond, WA, United States) and GraphPad Prism 6 software (GraphPad, San Diego, CA, United States) were used for statistical analyses. Data are expressed as mean ± SD. A one-way analysis of variance (ANOVA) and least significant difference (LSD) tests were used to compare the treatments.

RESULTS AND ANALYSIS

Expression and Subcellular Localization of MYB37 in Arabidopsis

Arabidopsis overexpressing MYB37 was obtained via transgenic technology to clarify the function of MYB37 in Arabidopsis under NaCl stress. Real-time quantitative reverse transcription PCR (qRT-PCR) results showed that MYB37 was significantly expressed in the OE-1 and OE-2 lines than in the other overexpression lines (the expression was more than 100-fold higher than that in Col-0; Figure 1A). Therefore, the OE-1 and OE-2 lines were selected for further functional verification tests. The OE-2 lines with the highest MYB37 expression were selected to determine the subcellular localization of MYB37-GFP fusion protein. High green fluorescent protein (GFP) activity was observed in the nuclear region of the elongation region of Arabidopsis root tips (Figure 1B), indicating that MYB37 is located in the nucleus.

Overexpression of the MYB37 Transcription Factor Improves Salt Stress Tolerance

The growth of taproots was not significantly different among Col-0, OE-1, and OE-2 Arabidopsis seedlings in normal media. Elongation of the taproots was inhibited in ½ MS media with NaCl. Although there were fewer yellow leaves in OE-1 and OE-2, the root length and number of leaves in the OE-1 and OE-2 plants were significantly higher than Col-0 (Figures 2A, C). The crown width of OE-2 line was slightly lower than that of Col-0 at the 4-week-old adult stage. However, the crown width was not significantly different between OE-1 and Col-0. MYB37 overexpression significantly relieved the salt damage symptoms of the OE-1 and OE-2 plants aged 4 weeks compared with the Col-0 plants. For instance, MYB37 overexpression changed the color of the leaves of Col-0 plants from yellow to green (Figure 2B).

Effects of MYB37 Overexpression on the Chlorophyll Content in Arabidopsis Leaves Under NaCl Stress

Quantitative analysis showed that the contents of Chl $a$, Chl $b$, and Chl $a+b$ and the Chl $a/b$ ratio of Col-0, OE-1, and OE-2 Arabidopsis leaves were not significantly different under normal conditions (Figure 3). NaCl stress degraded chlorophyll

FIGURE 1 | Detection of MYB37 expression level in Col-0 and overexpressed plants using qRT-PCR (A) and subcellular localization of MYB37 (B).
and decreased Chl $a/b$ ratio in Arabidopsis leaves. However, the contents of Chl $a$, Chl $b$, and Chl $a+b$ were significantly higher in OE-1 and OE-2 lines than in Col-0 under NaCl stress, except for the Chl $b$ content, which was not significantly different between the OE-2 lines and Col-0 (Figures 3A–C). Additionally, the Chl $a/b$ ratio was higher in the OE-1 and OE-2 lines under NaCl stress [20.97 and 7.52% ($p > 0.05$), respectively] than in Col-0 (Figure 3D).

**Effects of MYB37 Overexpression on the**

**PSII and PSI Activities in Arabidopsis Leaves Under NaCl Stress**

Although the relative fluorescence intensity from point J to point P on the OJIP curve was lower in Col-0 Arabidopsis leaves than in OE-1 and OE-2 lines (Figure 4A), $F_v/F_m$ was not significantly different (Figure 4C). The relative fluorescence intensity of point O slightly changed in Col-0 Arabidopsis leaves. However, the relative fluorescence intensity from point J to point P significantly decreased, and the OJIP curve became relatively flat. The relative fluorescence intensity of OE-1 and OE-2 lines slightly changed (Figure 4B). Compared with OE-1 and OE-2 lines, NaCl stress significantly decreased $F_v/F_m$ in Col-0 (Figure 4C). Similarly, although the amplitude of $MR_{820}$ curve was slightly lower in Col-0 Arabidopsis leaves than in the OE-1 and OE-2 lines under non-stress conditions (Figure 4D), $\Delta II/I_0$ was not significantly different. Moreover, the amplitude of $MR_{820}$ curve and $\Delta II/I_0$ of Arabidopsis leaves decreased under NaCl stress (Figure 4E). However, $\Delta II/I_0$ was significantly decreased in Col-0 compared with OE-1 and OE-2 lines under salt stress (Figure 4F).

**Effects of MYB37 Overexpression on the**

**PSII Receptor Side and Donor Side Electron Transport in Arabidopsis Leaves Under NaCl Stress**

O-P normalization of the original OJIP curve showed that the relative fluorescence intensity of each point on the OJIP curve was not significantly different among Col-0 Arabidopsis leaves, OE-1, and OE-2 lines under non-stress conditions (Figure 5A). However, the relative fluorescence intensity of point J on the OJIP curve of Col-0 Arabidopsis leaves substantially changed under NaCl stress compared with OE-1 and OE-2 lines (Figure 5B). The O-P normalized curves of Col-0, OE-1, and OE-2 leaves under NaCl stress were compared with the O-P normalized curves under non-stress. The relative fluorescence intensity at point J on Col-0 curve significantly increased, while it decreased on OE-1 and OE-2 curves (Figure 5C). However, the relative fluorescence intensity was not significant in the quantitative analysis of $V_f$. Only the $V_f$ of Col-0 increased by 26.12% under NaCl stress ($p < 0.05$; Figure 5G). Furthermore, the O-J normalized curve of the Col-0, OE-1, and OE-2 leaves were not significantly different under non-stress and NaCl stress conditions (Figures 5D–E). The O-J standardization
FIGURE 3 | Effects of MYB37 overexpression on Chl $a$ content (A), Chl $b$ content (B), Chl $a+b$ content (C), and Chl $a/b$ ratio (D) in Arabidopsis leaves under NaCl stress. Data are expressed as means ± SE of three replicated experiments ($n=3$). Different small letters indicate significant differences ($p<0.05$).

FIGURE 4 | Effects of MYB37 overexpression on OJIP curve (A, B), MR$_{820}$ curve (D, E), $F_v/F_m$ (C), and $\Delta I/I_o$ (F) in Arabidopsis leaves under NaCl stress. Data are expressed as means ± SE of three replicated experiments ($n=3$). Different small letters indicate significant differences ($p<0.05$).
curves of Col-0, OE-1, and OE-2 Arabidopsis leaves under NaCl stress were compared with those under non-stress conditions. The relative fluorescence intensity at point K of Col-0, OE-1, and OE-2 curves slightly decreased under NaCl stress (Figures 5F, H).

**Effects of MYB37 Overexpression on the Energy Distribution Parameters of the PSII Reaction Center in Arabidopsis Leaves Under Salt Stress**

Compared with Col-0, MYB37 overexpression did not significantly affect the energy allocation parameters Y(II), Y(NO), and Y (NPQ) of the PSII reaction center in Arabidopsis leaves under non-stress conditions (Figure 6). NaCl stress reduced the proportion of Y(II) in Arabidopsis leaves while it increased the proportion of Y(NO) and Y(NPQ). However, Y(II) and Y(NPQ) were significantly higher in the OE-1, and OE-2 Arabidopsis leaves than in Col-0 under NaCl stress. In contrast, Y(NO) was significantly lower in OE-1, and OE-2 Arabidopsis leaves than in Col-0.

**Effects of MYB37 Overexpression on the Contents of ROS and MDA in Arabidopsis Leaves Under Salt Stress**

NBT and DAB staining were used to detect the accumulation of O$_2^-$ and H$_2$O$_2$ in Arabidopsis leaves. Less blue sediment accumulated in the OE-1 and OE-2 leaves than in Col-0 under NaCl stress, similar to the accumulation of H$_2$O$_2$ (yellowish-brown sediment; Figures 7A, B). However, the rate of O$_2^-$/H$_2$O$_2$ production and MDA contents was not significantly different among Col-0, OE-1, and OE-2 lines under non-stress conditions. In contrast, NaCl stress significantly increased the rate of O$_2^-$ and H$_2$O$_2$ production and MDA contents of Arabidopsis. Nevertheless, O$_2^-$, H$_2$O$_2$, and MDA contents were significantly lower in OE-1 and OE-2 lines than in Col-0 (Figures 7C-E), consistent with the in situ staining results of O$_2^-$ and H$_2$O$_2$. 

---

**FIGURE 5** | Effects of MYB37 overexpression on standardized O-P curve (A, B), △V$_{o-p}$ curve (C), standardized O-J curve (D, E), △V$_{o-j}$ curve (F), V$_{o}$ (G), and V$_{k}$ (H) in Arabidopsis leaves under NaCl stress. Data are expressed as means ± SE of three replicated experiments (n = 3). Different small letters indicate significant differences (p < 0.05).
Effects of MYB37 Overexpression on Osmotic Regulatory Substances in Arabidopsis Leaves Under Salt Stress

The SS, SP, and Pro contents of OE-1, OE-2, and Col-0 were not significantly different under non-stress conditions (Figures 8A–C). However, NaCl stress significantly increased the contents of SS and Pro in Arabidopsis leaves, while it significantly decreased SP contents. Moreover, SS and Pro contents were significantly lower in OE-1 and OE-2 Arabidopsis leaves than in Col-0 under NaCl stress (Figures 8A–C), while SP content was significantly higher than that of Col-0 (Figure 8B).

DISCUSSION

The ability of transgenic overexpression lines or the loss of function mutants to tolerate abiotic stress is associated with reduced growth or loss of seed productivity (Yu et al., 2016a, 2016b). For instance, although MYB52/MYB96 overexpression confers a dwarf phenotype, while MYB44/MYB61 overexpression reduces seed productivity, the overexpression of these genes improves tolerance to drought or salt stress (Jung et al., 2008; Seo et al., 2009; Park et al., 2011; Romano et al., 2012). In this study, the crown width was slightly lower in Arabidopsis OE-2 line overexpressing MYB37 than in the wild type. However, MYB37 overexpression in A. thaliana maintained green leaves under NaCl stress and significantly alleviated salt stress symptoms. Photosynthesis promotes plant growth and development by providing energy. The photosynthesis of green plants primarily
depends on the absorption of light energy by chlorophyll. Therefore, chlorophyll degradation directly reduces the photosynthetic capacity of plants (Zhang et al., 2020d; Siddiqui et al., 2022). Studies have shown that salt stress can inhibit chlorophyll synthesis or degradation in plant leaves (Alaghabary et al., 2005; Ahanger et al., 2019). Herein, salt stress reduced the chlorophyll content of Arabidopsis leaves. Yang et al. (2011) showed that salt stress reduces chlorophyll content in plants through the disruption of Na$^+$ ion balance and activity of some proteases. Tulay et al. (2015) also found that salt stress increases the activity of chlorophyllase in *Spergularia marina* (Caryophyllaceae), decreases the content of Mg$^{2+}$ ions, accelerates the degradation of chlorophyll, inhibits the function of pigment protein complex, and the leaves become yellow or even fall off. Herein, *MYB37* overexpression delayed chlorophyll degradation under salt stress and alleviated chlorophyll reduction effect, especially Chl a, similar to the results of Bundó et al. (2022). *MYB37* overexpression can exhume or compartmentalize Na$^+$ in the cytoplasm into vacuoles, regulate the concentration of Na$^+$ in cells and maintain intracellular ion homeostasis by increasing the expression of Na$^+$/H$^+$ antiporter NHX1 in the vacuolar membrane, thus delaying chlorophyll degradation and enhancing salt tolerance (Zhao et al., 2019). The MYB transcription factor also reduces chlorophyll degradation in birch (*Betula* sp.) leaves (Zhou and Li., 2016) and tobacco (*Nicotiana benthamiana*) leaves (Pushp et al., 2015).

Chlorophyll fluorescence can be used to analyze the absorption and utilization of light energy by photosynthesis (Dimitrova et al., 2020; Zhang et al., 2020c). In this study, chlorophyll fluorescence curves (OJIP and MR$_\text{so}$ curves) were used to study the PSII and PSI activities of wild-type Arabidopsis Col-0 and Arabidopsis overexpressing *MYB37* under salt stress. $F_o/F_m$ and $\Delta I/\Delta I$ are key indexes of photochemical activity in PSII (Giannakoula and Ilias, 2007) and the activity of PSI (Wang et al., 2019), respectively. Herein, salt stress significantly reduced the $F_o/F_m$ and $\Delta I/\Delta I$ levels in wild-type *A. thaliana* Col-0 compared with normal growth conditions. However, $F_o/F_m$ and $\Delta I/\Delta I$ levels were not significantly changed in the OE-1 and OE-2 lines of *A. thaliana* overexpressing MYB37. Additionally, $F_o/F_m$ and $\Delta I/\Delta I$ were significantly higher in the OE-1 and OE-2 lines than in Col-0 under salt stress. Salt stress inhibits the activities of PSII and PSI in the leaves of sorghum (*Sorghum bicolor* L.; Zhang et al., 2018b) and halophytic soybean (*Glycine soja*; Yan et al., 2020). Sudhir and Murthy (2004) showed that salt stress inhibits PSII and PSI activities in leaves due to the accumulation of Na$^+$ in chloroplasts. In this study, $\frac{F_o}{F_m}$ and $\Delta I/\Delta I$ were significantly higher in the OE-1 and OE-2 lines than in the wild type, indicating that *MYB37* can improve photosynthesis by increasing the activities of PSII and PSI, thus enhancing salt tolerance. Pushp et al. (2015) also found that *SbMYB15* improves salt tolerance and dehydration in *Salicornia brachia* (highly tolerant to salt) by increasing PSII activity. The electron donor and acceptor sides of the PSI reaction center inhibit photosynthetic electron transport in plants under adverse environmental conditions (Zhang et al., 2020a). $V_j$ on the OJIP curve can reflect the accumulation of $Q_a$. The enhancement of $V_j$ indicates that the electron transfer from $Q_a$ to $Q_b$ on the PSI receptor side is blocked (Zhang et al., 2016). The change of $V_j$ is a specific marker of whether the oxygen-evolving complex (OEC) activity of the PSI electron donor side oxygen release complex is damaged (Zhang et al., 2020d). In this study, salt stress only increased the $V_j$ value of wild-type Arabidopsis Col-0 curve while slightly changing the $V_K$ value, indicating that salt stress inhibited the electron transfer from $Q_a$ to $Q_b$ on the PSI receptor side of wild-type Arabidopsis leaves. Salt stress did not affect the activity of OEC on the PSI electron donor side (Zhang et al., 2019) also found that salt stress affects OEC activity on the electron donor side of PSI in leaves of mulberry (*Morus alba* L.) after salt and alkali stress treatment. Lu and Vonskak (2002) also found that salt stress reduces the reception of upstream $Q_j$ electrons by plastoquinone $Q_j$ (connecting the PSI and PSI reaction centers) in cyanobacteria (*Spirulina platensis*), thus decreasing the electron transfer speed of the entire photosynthetic electron transport chain. Previous studies have also shown that increased Na$^+$ content in the cytoplasm and extracellular tissues under salt stress affects the activity of the photosynthetic electron transport chain (Kao et al., 2003). Herein, MYB37 overexpression alleviated the electron transfer from $Q_j$ to $Q_k$ on the PSI receptor side of Arabidopsis under salt stress. Pushp et al. (2015) also proposed that *SbMYB15* could improve the photoprotection.

**FIGURE 8** | Effects of *MYB37* overexpression on SS content (A), SP content (B), and Pro content (C) in Arabidopsis leaves under NaCl stress. Data are expressed as means ± SE of three replicated experiments ($n$ = 3). Different small letters indicate significant differences (p < 0.05).
mechanism of transgenic lines under salt stress by enhancing electron transfer from the PSII reaction center to the primary quinone receptor. Although stress inhibits the activity of PSII and even leads to the inactivation of PSII response centers, plants adapt to stress by regulating the energy distribution of PSII response centers, such as by increasing energy dissipation (Dimitrova et al., 2020; Sun et al., 2021). In this study, salt stress significantly decreased Y(II) of leaves of A. thaliana, while it significantly increased Y(NO) and Y(NPQ). These results indicate that A. thaliana adapts to salt stress by increasing its energy dissipation mechanisms. Bashir et al. (2021) showed that salt stress decreases Y(II) in moringa (Moringa oleifera), while it increases Y(NO) and Y(NPQ), consistent with this study. Herein, MYB37 overexpression increased Y(II) and Y(NPQ) of Arabidopsis under salt stress but decreased the Y(NO). These results indicate that MYB37 overexpression increases the activity of PSII and regulates energy dissipation in Arabidopsis leaves under salt stress, thus decreasing the proportion of inactivated reaction centers.

Photosynthesis inhibition produces excess electrons and energy in the photosynthetic electron transport chain, resulting in an ROS burst and peroxidation damage (Kalaji et al., 2014; Wang et al., 2021b). Wang et al. (2021a) found that salt stress significantly increases O$_2$ production rate and the contents of H$_2$O$_2$ and MDA of alfalfa (Medicago sativa) leaves. Zhang et al. (2018a) also found that salt stress increases the rate of O$_2$ production and H$_2$O$_2$, content of mulberry leaves. In this study, salt stress significantly increased the rate of O$_2$ production and the contents of H$_2$O$_2$ and MDA of Arabidopsis leaves. However, ROS and MDA contents were lower in Arabidopsis OE-1 and OE-2 overexpressing MYB37 than in the wild type under salt stress, consistent with the results of Zhang et al. (2020e) and Huang et al. (2018) in Arabidopsis, tobacco (Pushp et al., 2015) and Tamarix hispida (Liu et al., 2021). The overexpression of stress tolerance genes can inhibit membrane damage and significantly reduce the accumulation of ROS and MDA under stress conditions. The content of osmotic regulators changes under osmotic stress, thus improving plant tolerance to abiotic stress (Li et al., 2019). Plants adapt to saline-alkali stress by regulating the accumulation of proline (Pro) and soluble sugar (SS; Ren et al., 2020). Previous studies have shown that Pro and SS regulate plant osmotic balance and improve salt or alkali tolerance (Kanu et al., 2019). Guo et al. (2011, 2017) showed that Pro is significantly accumulated in maize (Zea mays L.) under salt stress. Wang et al. (2021a, 2021b) also found that alfalfa leaves can adapt to salt stress by increasing the content of SS and Pro. This experiment also found similar findings described above. In summary, the contents of SS and Pro were significantly increased in Arabidopsis leaves under salt stress, thus reducing salt stress damage to plants. Moreover, MYB37 overexpression enhanced Arabidopsis OE-1 and OE-2 resistance to salt stress and decreased SS and Pro contents. Pushp et al. (2015) also found similar results in tobacco overexpressing SbMYB15 under salt stress. Soluble protein (SP) is also a key osmoregulatory substance. Relevant studies have shown that the SP content is substantially accumulated in plant leaves under salt stress (Zhuang et al., 2010; Bai et al., 2013; Hong et al., 2014). In this experiment, salt stress degraded SP in Arabidopsis leaves, similar to Gulen et al. (2006) (strawberry, Fragaria x ananassa), Liu et al. (2006) (rice and Oryza sativa). However, the accumulation of SP was higher in OE-1 and OE-2 leaves than in the wild type under salt stress, indicating that MYB37 overexpression promotes protein synthesis of Arabidopsis plant under salt stress and maintains water transport and photosynthetic function of leaves, thus promoting plant growth and salt tolerance (Cernusak et al., 2007).

CONCLUSION

Compared with the wild-type (Col-0) Arabidopsis, the overexpression of MYB37 significantly alleviated the symptoms of salt injury in plants under NaCl stress and alleviated chlorophyll degradation (particularly Chl a) under NaCl stress. MYB37 overexpression also alleviated the photoinhibition of PSII and PSI in Arabidopsis under NaCl stress, particularly by alleviating the electron transfer from Q$_a$ to Q$_b$ on the PSII receptor side. MYB37 overexpression increased the PSII activity, and regulated energy dissipation in Arabidopsis leaves under salt stress, thus decreasing the proportion of inactivated reaction centers. MYB37 overexpression also reduced the accumulation of ROS and MDA in Arabidopsis leaves under NaCl stress, thus alleviating the oxidative damage. In addition, MYB37 overexpression alleviated SP degradation in Arabidopsis leaves under salt stress. However, MYB37 overexpression did not enhance plant adaption to NaCl stress by accumulating SS and Pro due to the strong resistance to NaCl stress.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding authors.

AUTHOR CONTRIBUTIONS

HZ and YY conceived and designed the experiments. YL, BT, and YW wrote the manuscript and prepared the figures and tables. All the authors performed the experiments and analyzed the data. YL, HZ, and YY reviewed drafts of the paper. Sun Guangyu supervised the work. All authors contributed to the article and approved the submitted version.
