Materials and Methods. Unless stated otherwise, reactions were performed in flame-dried glassware under a positive pressure of nitrogen using freshly distilled solvents. Thin-layer chromatography (TLC) was performed using E. Merck silica gel 60 F\textsubscript{254} precoated plates (0.25 mm). Flash chromatography was performed using Baker silica gel (40 \textmu m particle size). NMR spectra were recorded on Varian Innova-500, or Mercury-400 instruments and calibrated using residual undeuterated solvent as an internal reference. IR spectra were recorded on Avatar 360 FT-IR spectrometer. Low-resolution mass (CI) spectra were obtained by using a Platform II mass spectrometer. High-resolution mass spectral analyses were performed at the Harvard University Mass Spectrometry Center. Analytical high performance liquid chromatography (HPLC) was performed on Isco 2350 Series or Waters 626 HPLC using the indicated chiral column. Gas chromatography (GC) analyses were performed on Hewlett-Packard 6850 Series GC System equipped with flame ionization detector using a J & W Scientific Cyclosil-B column (30 m x 0.25 mm). Commercial grade reagents and solvents were used without further purification except as indicated below. Dichloromethane was distilled from calcium hydride. Toluene was distilled from sodium. 2-Methylnaphthalene-1, 4-dione (Aldrich), naphthalene-1, 4-dione (Aldrich), 2-bromo-6-methyl-1,4-benzoquinone (Sigma-Aldrich), 1,4-benzoquinone (Aldrich) and 2-t-butyl-1,4-benzoquinone were used after recrystallization with a mixture of ethyl acetate and hexanes. 2-Triisopropylsilyloxy-1,3-butadiene,\textsuperscript{1} 2, 3, 5-trimethyl-1,4-benzoquinone,\textsuperscript{2} 1-bromo-2, 4-

General Procedure for the Preparation and Use of Chiral Diels-Alder Catalysts. A 100-mL,
two-necked, round-bottomed flask equipped with a stir bar, a glass stopper and a 50-mL
pressure-equalizing addition funnel (containing a cotton plug and ca. 10 g of 4 molecular sieves,
and functioning as a Soxhlet extractor) fitted on top with a reflux condenser and a nitrogen inlet
adaptor was charged with (S)-(--)-α,α-diphenyl-2-pyrrolidinemethanol (82.0 mg, 0.324 mmol,
from Lancaster), tri-o-tolylboroxine (38.0 mg, 0.107 mmol) and 25 mL of toluene. The
resulting solution was heated to reflux (bath temperature ~ 145 °C). After 3 h, the reaction
mixture was cooled to ca. 60 °C and the addition funnel and condenser were quickly replaced
with a short-path distillation head. The mixture was concentrated by distillation (air-cooling) to
a volume of ca. 5 mL. This distillation protocol was repeated three times by re-charging with 3 x
5 mL of toluene. The solution was then allowed to cool to room temperature and the distillation
head was quickly replaced with a vacuum adaptor. Concentration in vacuo (ca. 0.1 mmHg, 1 h)
afforded the corresponding oxazaborolidine as clear oil, which can then be dissolved in CH₂Cl₂
and used in two Diels-Alder experiments.

To an aliquot of the oxazaborolidine precursor (0.160 mmol, theoretical) in 1.0mL of CH₂Cl₂ at
–25 °C was added trifluoromethanesulfonimide (0.20 M solution in CH₂Cl₂, freshly prepared,
667 µL, 0.133 mmol) dropwise. After 10 min at –25 °C, a colorless homogeneous catalyst
solution was ready for use in the Diels-Alder reactions.

To a catalyst solution in CH₂Cl₂ (1.0 mL) were successively added a solution of 1, 4-benzoquinone (0.665 mmol) in CH₂Cl₂ (0.7~1.0 mL) and 2-triisopropylsilyloxy-1,3-butadiene (194 µL, 166 mg, 0.732 mmol) at –78 °C. The reaction mixture was stirred at the temperature indicated in Table 1-3 and monitored by ¹H NMR or TLC. When it was judged to be complete, dichloromethane was removed by rotary evaporation and water (5mL) and hexanes (3mL) were added. The aqueous layer was extracted with hexanes (4 x 5mL). The combined extract was dried over anhydrous Na₂SO₄ and concentrated to afford the corresponding adduct which was pure enough for the most purposes. Further purification was performed by silica gel chromatography (Table 1), low temperature (-78 °C) silica gel chromatography or recrystallization (Table 2, 3). The corresponding racemic products for the determination of enantioselectivity were prepared by using ethylaluminum dichloride (20 mol %) or anhydrous LiClO₄ as a Lewis acid catalyst or thermal reaction.

Determination of Regioselectivity, Enantioselectivity and Absolute Configuration of the Diels-Alder Adducts Reported in Tables 1-3.

Table 1, entry 1: Regioselectivity and enantioselectivity were determined by HPLC analysis using a Regis (S, S)-Whelk-O1 column (0.2% i-PrOH in hexanes for elution; 1mL/min; λ 254 nm); retention times: 13.1 min (major), 15.5 min (minor), 18.6 min (regioisomer). The absolute configuration was determined by comparison with an authentic sample prepared from (-)-(4aR, 8aS)-3-iodo -2, 4a -dimethyl-6 -(triisopropylsilyl)oxy - 4a, 5, 8, 8a - tetrahydro -1, 4-naphthoquinone (substitution of iodine with methyl group) and HPLC analysis.

10 After hexanes extraction, the aqueous solution was treated with aqueous 2N NaOH solution and extracted with dichloromethane. The combined extract was dried over Na₂SO₄, concentrated and purified by column chromatography (elution with EtOAc) to afford pure ligand (95-99% recovery).
