LIS1 determines cleavage plane positioning by regulating actomyosin-mediated cell membrane contractility

Abstract Heterozygous loss of human PAFAH1B1 (coding for LIS1) results in the disruption of neurogenesis and neuronal migration via dysregulation of microtubule (MT) stability and dynein motor function/localization that alters mitotic spindle orientation, chromosomal segregation, and nuclear migration. Recently, human-induced pluripotent stem cell (iPSC) models revealed an important role for LIS1 in controlling the length of terminal cell divisions of outer radial glial (oRG) progenitors, suggesting cellular functions of LIS1 in regulating neural progenitor cell (NPC) daughter cell separation. Here, we examined the late mitotic stages NPCs in vivo and mouse embryonic fibroblasts (MEFs) in vitro from Pafah1b1-deficient mutants. Pafah1b1-deficient neocortical NPCs and MEFs similarly exhibited cleavage plane displacement with mislocalization of furrow-associated markers, associated with actomyosin dysfunction and cell membrane hypercontractility. Thus, it suggests LIS1 acts as a key molecular link connecting MTs/dynein and actomyosin, ensuring that cell membrane contractility is tightly controlled to execute proper daughter cell separation.

Introduction Lissencephaly (smooth brain) is a brain malformation disorder associated with haploinsufficiency of Lissencephaly-1 (LIS1), also called PAFAH1B1 (Platelet-activating factor acetylhydrolase IB subunit alpha) (Dobyns et al., 1993; Hattori et al., 1994; Reiner et al., 1993; Moon and Wynshaw-Boris, 2013). At the molecular level, LIS1 is an important regulatoratory protein controlling cytoplasmic dynein and microtubules (MTs), that is also known to have dual roles coordinating both MTs and the actin cytoskeleton (Kholmanskikh et al., 2003; Kholmanskkh et al., 2006; Jheng et al., 2018). Besides pivotal roles of LIS1 in post-mitotic neuronal migration, Pafah1b1 mouse mutant studies suggest additional cellular functions of LIS1 in neocortical neural progenitor cell (NPC) division by regulating mitotic spindle orientation and cell fate (Yingling et al., 2008; Youn et al., 2009; Hippenmeyer et al., 2010; Bershteyn et al., 2017; Moon et al., 2014). The mitotic phenotypes of Pafah1b1 mutants are closely related and consistent with those of other mutants of MT/dynein-associated proteins such as LGN, NDE1, and NDEL1 (Bradshaw and Hayashi, 2017; Doobin et al., 2016; Wynne and Vallee, 2018). However, unlike these other mouse mutants of LIS1-interacting proteins, Pafah1b1 mutants displayed a significant decrease in neuroepithelial stem cells in the neocortex and subsequent neonatal death compared with a less catastrophic phenotype seen in radial glial (RG) progenitors (Yingling et al., 2008). Our recent studies with human-induced pluripotent...
stem cells (iPSCs) of Miller-Dieker syndrome, a severe form of lissencephaly caused by heterozygosity of more than 20 genes including PAFAH1B1, demonstrated a prolongation of mitotic division time of oRG progenitors but not ventricular zone radial glial (vRG) progenitors (Bershteyn et al., 2017). All of these previous studies suggest that cellular functions of LIS1 other than MT/dynein-mediated mitotic spindle regulation dictate further mitotic progression from mitotic (M) phase to anaphase/telophase in late stages of mitosis and daughter cell separation.

Although the functions of LIS1 in F-actin regulation have been studied previously, its downstream cellular signaling pathways that regulate actomyosin during late mitosis and cytokinesis has not been explored. When cytokinesis is initiated, MTs provide positional cues for the cleavage furrow location and membrane ingestion at the equatorial cortex by inducing central spindle assembly (Bement et al., 2005; von Dassow, 2009; Werner et al., 2007). At this point, dynamic crosstalk between astral MTs and cortical filamentous actin (F-actin) transmit inhibitory signals at the polar cortex, which indirectly instructs cleavage furrow positioning to the equatorial cortex (Canman et al., 2003; Fee and von Dassow, 2008; Murthy and Wadsworth, 2008). During cleavage plane formation, a small GTPase RhoA functions as a master regulator of cytokinetic furrow ingestion (Bement et al., 2005; Nishimura and Yonemura, 2006) that recruits contractile ring components, including the scaffold protein Anillin (D’Avin et al., 2008; Gregory et al., 2008; Oegema et al., 2000; Piecky and Glotzer, 2008) and Septin (Kinosita et al., 2002; Maddox et al., 2007; Oegema et al., 2000). At the same time, Myosin II accumulates at the equatorial cortex and serves as a constriction force generator by interacting with F-actin (Glotzer, 2005; Straight et al., 2003; Zhou and Wang, 2008). However, when coordination between MTs and F-actin is perturbed, abnormally fewer or elongated astral MTs destabilize the cleavage furrow. This MT dysfunction induces actomyosin dysregulation, leading to cell membrane hyper-contractility, RhoA and F-actin mislocalization outside of the midzone/cleavage furrow, cell shape oscillation, and subsequent mitotic failure (Canman et al., 2003; Murthy and Wadsworth, 2008; Rankin and Wodeman, 2010; Watanabe et al., 2008). It is important to note that LIS1 is involved in astral MT movements and F-actin polymerization, so it is possible that LIS1 contributes to important cellular processes during cytokinesis by regulating actomyosin and other cleavage furrow-associated proteins during late stages of mitosis and cytokinesis.

We hypothesized that the LIS1-dynein-MT network may be essential for cytokinesis, perhaps by fine-tuning actomyosin and cell membrane contractility. Therefore, we assessed the mitotic phenotypes of neocortical from Pafah1b1-deficient mouse embryonic fibroblasts (MEFs), using time-lapse live-cell imaging. Through imaging of Pafah1b1-deficient MEFs, we found severe defects in cleavage plane positioning and dysregulation of cell membrane contractility. Here we demonstrate that LIS1 determines cleavage plane positioning through a RhoA-actomyosin signaling pathway, defining a novel molecular mechanism of LIS1 underlying spatiotemporal regulation of cell membrane contractility during mitotic cell division.

Results

Mislocalization of RhoA and Anillin in Pafah1b1 mutant neocortical neural progenitor cells (NPCs)

To elucidate molecular mechanisms underlying LIS1-dependent NPC regulation during neocortical development, mitotic phenotypes of Pafah1b1-deficient NPCs were analyzed by conducting genetic and immunohistochemical approaches on mouse neocortices derived at embryonic day 14.5 (E14.5) (Figure 1A–E). We took advantage of mosaic analysis with double markers on chromosome 11 mouse line (MADM-11; Hippenmeyer et al., 2010), since the Pafah1b1 is located on chromosome 11 away from the centromere. To deplete Pafah1b1 sparsely in neocortical NPCs during early embryonic development, we first generated MADM-11TG/TG,Pafah1b1mut (TG: tdTomato-GFP fusion) mice co-expressing the heterozygous Pafah1b1 knock-out (KO) allele. These mice were mated with MADM-1f1GT/GT,Emx1Cre/+ (GT: GFP-tdTomato fusion) to generate the experimental mosaic animals which carried sparsely labeled NPCs with different expression levels of LIS1 (MADM-1f1GT/GT,Pafah1b1mut;Emx1Cre/+, abbreviated as Pafah1b1-MADM) (Figure 1B). In this line, we identified three distinct subpopulations of labeled NPCs with different LIS doses; Pafah1b1+/- (red, labeled with tdTomato, 100%...

NPCs (o) Complete knock-out (KO) of Pafah1b1 heterozygous (Pafah1b1<sup>+/−</sup>) NPCs. (h) Complete knock-out (KO) of Pafah1b1 (Pafah1b1<sup>ko/ko</sup>) in NPCs results in mitotic arrest at the prometaphase- or metaphase-like time-points. (D) (j), WT NPCs displayed apical membrane-associated RhoA during cytokinesis. (k,l) RhoA was also co-localized with the midbody, at the future cleavage furrow. (E) (m,n). The cytosol from only one daughter cell retained RhoA-positive puncta in WT NPCs. (o) Complete KO of Pafah1b1 (Pafah1b1<sup>ko/ko</sup>) resulted in detachment of NPCs away from the RhoA-positive apical membrane. Gray arrowheads: ventricular surface (apical). Scale bars: 5 μm. Quantitative data were included in Figure 1—source data 1.

The online version of this article includes the following source data for figure 1:

**Source data 1.** Quantification of apical NPCs (RGs).

LIS1 wild-type (WT) levels, Pafah1b1<sup>+/+</sup> (yellow, double positive for GFP and tdTomato, 50% LIS1 WT levels), and Pafah1b1<sup>ko/ko</sup> (green, labeled with GFP, 0% LIS1) NPCs in an unlabeled Pafah1b1<sup>+/+</sup> heterozygous background. The fluorescence of each cell enabled us to distinguish the genotype of each cell. The same mating scheme was used to generate WT control animals (MADM-1<sup>GT/GT</sup>, Emx1<sup>Cre/+</sup>, abbreviated as WT-MADM) where green, red, and yellow cells are all WT expressing normal levels of 100% LIS1.

To determine whether Pafah1b1 deficiency in neocortical NPCs results in displacement of the mitotic cleavage plane with abnormal distribution of contractile components, we assessed Anillin distribution in Pafah1b1-MADM neocortices compared with those of WT-MADM at E14.5. In the WT-MADM neocortex, Anillin was accumulated at the midzone during metaphase-to-anaphase (Figure 1A–a,b) and was enriched by forming a ‘U’ shape (basal-to-apical ingression) at the midbody of NPCs, consistent with previous observations of normal NPC cleavage in WT mice (Kosodo et al., 2008; Figure 1A–c,d). In the Pafah1b1-MADM neocortices, the tdTomato-positive WT NPCs (red, Pafah1b1<sup>+/+</sup>) similarly displayed a normal distribution of Anillin at the apical cleavage furrow between the two daughter cells (Figure 1C–e). The tdTomato- and GFP-double-labeled Pafah1b1 heterozygous NPCs (yellow, Pafah1b1<sup>+/−</sup>) did not display an Anillin-rich ring associated with the midbody (Figure 1C–f,g). The Pafah1b1-MADM (Figure 1B–C) neocortex displayed a profound decrease in GFP-positive Pafah1b1 homozygous KO apical NPCs located at the ventricular zone (green, Pafah1b1<sup>ko/ko</sup>). These apical Pafah1b1<sup>ko/ko</sup> NPCs were mostly found at prometaphase or metaphase and located at the ventricular surface with no obvious cell membrane-associated Anillin with dispersed patterns (Figure 1C–h), probably due to mitotic arrest after complete loss of LIS1 (Yingling et al., 2008). Abnormal distribution of Anillin in Pafah1b1 mutant NPCs (Pafah1b1<sup>ko/ko</sup>) implies that LIS1 is an important cell determinant for neocortical NPC cell cleavage and daughter cell separation during cytokinesis in a cell-intrinsic manner.

In apical NPCs of the neocortex, the highest expression of RhoA was detectable at the ventricular surface where NPC cleavage furrows were found (Gauthier-Fisher et al., 2009; Lian et al., 2019). Overexpression of dominant-negative forms of RhoA in mouse NPCs in vitro induced mislocalization of cleavage furrow with diffuse and dispersed contractile ring (Lian et al., 2019), suggesting that RhoA dictates cytokinetic progression and cleavage furrow specification. In the present study, cell membrane-bound forms of RhoA in apical NPCs were identified by fixing the embryonic brains with a 10% trichloroacetic acid (TCA) solution. In the control WT-MADM neocortex (MADM-1<sup>GT/GT</sup>, Emx1<sup>Cre/+</sup>, tdTomato) illuminated the cytoplasm of dividing NPCs. At metaphase, RhoA was associated with the apical cell membrane of WT NPCs proximal to the ventricular surface (Figure 1D–i). At telophase, RhoA was enriched at the midbody located at the ventricular surface, indicating separation of the two daughter cells (Figure 1D j,k,l). However, in the Pafah1b1-MADM neocortex (MADM-1<sup>GT/GT</sup>, Emx1<sup>Cre/+</sup>, tdTomato- and GFP-double-labeled Pafah1b1 heterozygous NPCs (yellow, Pafah1b1<sup>+/−</sup>) displayed an unequal distribution of RhoA skewed to the cytoplasm of only one daughter cell (Figure 1E–m,n). The GFP-positive Pafah1b1 KO NPCs (green, Pafah1b1<sup>ko/ko</sup>) were sparsely found at the prometaphase or metaphase with apical membrane-associated RhoA (Figure 1E–o). Together, mislocalization of Anillin and RhoA in Pafah1b1 mutant neocortical NPCs (Pafah1b1<sup>ko/ko</sup>) indicates that LIS1 may contribute to cleavage plane specification and positioning during late stages of apical NPC mitosis.
Mislocalization of Anillin in apical NPCs from Pafah1b1 heterozygous neocortex

We next asked whether Pafah1b1 heterozygosity leads to changes in cytoarchitecture of the apical NPC niche at the ventricular surface of the neocortex. We deleted one copy of Pafah1b1 in neocortical NPCs by mating Pafah1b1 conditional knock-out (CKO) line with the GFAP-Cre line (Zhuo et al., 2008). In control neocortex (Pafah1b1h+/c− without Cre, hc: hypomorphic conditional), NPCs undergoing vertical divisions (with a vertical cleavage plane angle) possessed basally located Anillin that gradually ingressed apically with the formation of the midbody, defining final location of cleavage furrow (basal-to-apical ingestion) (Figure 2A), consistent with previous findings (Kosodo et al., 2008). NPCs undergoing horizontal or oblique divisions maintained a straight line of Anillin-rich immunoreactive signal in the junctional plate between two daughter cells (Figure 2B), suggesting normal cleavage furrow formation at the midzone between the two daughter cells. There were reduced numbers of NPCs undergoing vertical divisions (42%) in NPC-specific Pafah1b1 heterozygous mutant neocortex (GFAP-Cre; Pafah1b1h+/c−) compared with those numbers (84%) in control neocortex (Pafah1b1h+c+), consistent with our previous findings (Yingling et al., 2008). In addition, NPCs undergoing oblique and horizontal divisions in Pafah1b1 heterozygous mutant neocortex displayed a diffuse pattern of Anillin associated with similar enrichment at both the apical and basal cell membrane. Only one apically attached daughter cell retained concentrated Anillin-positive puncta at the ventricular surface (Figure 2B–f,g,i), suggesting that Pafah1b1 heterozygosity resulted in Anillin mislocalization during late mitosis of apical NPCs.

An imbalance in symmetric versus asymmetric NPC divisions after dose-dependent reduction of LIS1

We hypothesized that Pafah1b1 mutant NPCs may display an imbalance in symmetric vs. asymmetric divisions due to defects in cleavage furrow patterning and cell membrane contractility. We previously reported that neocortical NPCs in Pafah1b1 mutants had reduced mitotic spindle angles because more cells displayed abnormal cleavage planes that were skewed to oblique and horizontal divisions (Yingling et al., 2008). Here, we analyzed neocortical NPC divisions by tracing the inheritance of atypical protein kinase C zeta (aPKC, PKCζ), an apical complex component, into each daughter cell. The cleavage furrow was identified by the location of Cadherin hole in the continuous line of N-Cadherin that indirectly indicates the contractile ring positioning (Marthiens and ffrench-Constant, 2009). The relative positioning of the mitotic spindle was defined by the midline between two chromosome sets. Thus, we determined that neocortical NPCs from Pafah1b1-deficient mutants (Pafah1b1h/cko) more frequently displayed unequal inheritance of aPKCζ to the daughter cells (Figure 3A–C). In addition, apical NPCs in Pafah1b1h/cko neocortices possessing horizontal cleavage planes displayed less polarized aPKCζ along the apical-basal axis (Figure 3B), indicating mild alterations of apical polarity in Pafah1b1-deficient neocortical NPCs. In Pafah1b1h+c− control neocortices, 30.7% of NPCs displayed unequal distribution of aPKCζ into the cytoplasm of the two daughter cells (presumably asymmetric divisions). However, in Pafah1b1h/cko brains, 68.8% of NPCs displayed unequal distribution (Figure 3C). These results suggest that Pafah1b1 deficiency in neocortical NPCs results in abnormal cleavage furrow positioning that may induce unequal inheritance and distribution of cell fate determinants into two daughter cells that ultimately leads to an increase in asymmetric (presumably neurogenic) NPC divisions.

Perturbed daughter cell separation and an increase in binucleation during mitosis of Pafah1b1 mutant MEF

We also tested whether Pafah1b1 deficiency impairs cleavage plane positioning and completion of mitosis in MEFs using time-lapse microscopy. We visualized mitotic events of late stages of mitosis of MEFs in vitro in greater detail than we could do in the neocortex in vivo. We examined the frequency of normal daughter cell separation with complete abscission from both WT MEFs (Pafah1b1+/−) and mutant Pafah1b1 compound heterozygous MEFs (Pafah1b1h/cko) expressing 35% of LIS1 compared to normal WT levels (Yingling et al., 2008). Sequential mitotic events were monitored by time-lapse live-cell imaging using mCherry-α-Tubulin, a fluorescently labeled MT marker, and histone 2B (H2B)-GFP, a chromosomal probe (Moon et al., 2014). A majority of WT MEFs displayed successful daughter cell separation (85.4 ± 6.1%), while in Pafah1b1h/cko MEFs, this frequency was decreased
Figure 2. Localization of Anillin-ring in neocortical NPCs from controls and GFAP-Cre-induced Pafah1b1 mutant mouse embryos. (A) Normal Anillin-ring distribution during cytokinesis of Pafah1b1 control (Pafah1b1<sup>hc/+</sup>) NPCs. hc: hypomorphic conditional allele, (a) Early anaphase, (b) Mid-anaphase with a basally located Anillin-ring, (c) ‘U’-like shape Anillin-ring at the cleavage furrow, (d) Midzone-specific Anillin localization. (a,b,c) Vertical cleavage plane (60°< \alpha < 90°), \alpha: spindle angle compared to the ventricular surface, (d) Oblique and horizontal cleavage plane (0°< \alpha < 60°). (B) Abnormal Anillin-ring localization during cytokinesis of Pafah1b1-deficient mutant NPCs (GFAP-Cre; Pafah1b1<sup>hc/+</sup>). (e) Basal and apical Anillin-rings at the equator of NPCs, (f,g) Moderately skewed Anillin-ring localization in only one daughter cell. (h) The equator-associated Anillin-ring was detected with tilted spindle angle in Pafah1b1-deficient NPCs. (i) Pafah1b1-deficient mutant NPCs displayed horizontal cleavage plane with apical membrane-associated Anillin puncta. Gray arrowheads: ventricular surface (apical). Scale bars: 5 \mu m. Quantitative data were included in Figure 2—source data 1.

Source data 1. Quantification of apical NPCs (RGs).
Figure 3. Alterations in symmetric and asymmetric divisions determined by equal vs. unequal inheritance of atypical PKC (aPKC, PKCζ) and Cadherin holes. (A) Normal cytokinesis in neocortical NPCs from Pafah1b1 controls (Pafah1b1^{hc/+}). Upper panel: Control NPCs displayed vertical cleavage with equal inheritance of aPKC and Cadherin hole. Lower panel: Control NPCs displayed vertical cleavage with unequal inheritance of aPKC and Cadherin hole – presumably reflecting an asymmetric neurogenic division. (B) Upper panel: Pafah1b1-deficient NPCs (Pafah1b1^{hc/ko}) displayed vertical cleavage Figure 3 continued on next page
with unequal inheritance of aPKC and Cadherin hole. Lower panel: Pafah1b1-deficient NPCs displayed horizontal cleavage with unequal and very skewed inheritance of aPKC and Cadherin hole. This Pafah1b1-deficient NPC retained less polarized aPKC/N-Cadherin protein distribution (less apical enrichment of aPKC and N-Cadherin) along the apical-basal axis. (C) Disturbances in the frequencies of equal vs. unequal inheritance of cell fate determinants in Pafah1b1-deficient NPCs. Gray arrowheads: ventricular surface (apical). Scale bars: 5 μm. Quantitative data were included in Figure 3—source data 1. The online version of this article includes the following source data for figure 3: Source data 1. Quantification of aPKC inheritance in apical NPCs (RGs).

(18.7 ± 8%) (Figure 4A). By contrast, binucleated daughter cells were increased in Pafah1b1hc/ko MEFs (40.1 ± 1.2%) relative to WT MEFs (5.1 ± 3.1%) (Figure 4B). To assess whether an increase in incomplete cell separation leads to changes in apoptotic cell death, we immunostained cleaved caspase-3. Pafah1b1hc/ko MEFs had an increased number of cleaved caspase-3-immunoreactive cells compared with WT, suggesting that Pafah1b1 deficiency induces more frequent apoptosis of MEFS (Figure 4C). We also confirmed an increase in cell death (from 3- to 6-fold) from live-cell imaging of Pafah1b1hc/ko MEFS.

To determine whether acute loss of Pafah1b1 also induces defective cell separation, we derived MEFS containing CKO alleles of Pafah1b1 and tamoxifen (TM)-inducible CAGG-CreERT2 line (Hayashi and McMahon, 2002) with the genotype CAGG-CreERT2; Pafah1b1hchc. We treated these MEFS with 4-hydroxy-TM for 12 hr and compared mitotic phenotypes with control MEFS (CAGG-CreERT2; Pafah1b1+/−). Similar to Pafah1b1hc/ko mutant MEFS, acute deletion of Pafah1b1 in TM-treated Pafah1b1 CKO MEFS (CAGG-CreERT2; Pafah1b1hchc +TM12 h) induced a decrease in normal daughter cell separation (36.6 ± 5.3%) compared with control levels (69.4 ± 4.3%) (Figure 4D). Consistently, a trend of frequent daughter cell separation failure and higher percentage of binucleation (25.8 ± 6.4%) than controls (CAGG-CreERT2; Pafah1b1+/− +TM12 h) (15.7 ± 6.1%) was observed from live-cell imaging (Figure 4E) but this was not statistically significant.

Cell shape oscillation and mitotic spindle rocking during mitosis of Pafah1b1 mutant MEFS

We analyzed movements of MT-enriched midbody and cleavage plane positioning throughout the entire mitotic cell cycle by live-cell imaging. Acute deletion of Pafah1b1 in MEFS (CAGG-CreERT2; Pafah1b1hc/hc +TM12 h) resulted in drastic cell shape oscillation (Figure 5A, Video 1), similar to the phenotypes described in Anillin-depleted cells (Echard et al., 2004; Kechad et al., 2012; Piekny and Glotzer, 2008; Straight et al., 2003; Zhao and Fang, 2005). At the anaphase onset of Pafah1b1 mutant MEFS, the midbody was properly positioned in the central spindle zone. However, the position of the midbody was gradually destabilized and began vigorously oscillating between the two daughter cells. Surprisingly, the initially separated chromosome sets moved back and forth between two daughter cells and mitotic spindle rocking was prominent throughout this process. This phenotype was previously termed ‘hyper-contractility’ in cells with depleted contractile ring components, and is caused by hyper-activity of the actomyosin during cytokinesis (Werner and Glotzer, 2008). Surprisingly, in one example seen in Pafah1b1 mutant MEFS (Figure 5B, Video 2), one daughter cell inherited two-sets of chromosomes with binucleation while the other daughter cell underwent cell death processes.

We next examined the incidence of the hyper-contractility phenotypes during MEF mitosis. WT MEFS rarely displayed oscillated cell membrane movements (3.6 ± 3.6%). By contrast, more than half of the mitoses (56.2 ± 8.4%) in Pafah1b1hc/ko MEFS exhibited the hyper-contractility phenotypes (Figure 5C). The incidence of ectopic membrane bulges was increased in Pafah1b1 mutant MEFS which prompted us to monitor cell shape changes and cell membrane dynamics by merging phase-contrast images in live-cell imaging analysis. We found that Pafah1b1hc/ko MEFS frequently showed cell membrane blebbing (Figure 5D) and the size of ectopic membrane blebs was much larger than those in WT MEFS. In accordance with these findings, the hyper-contractility phenotypes with cell membrane blebbing were more frequent in Pafah1b1 CKO MEFS (CAGG-CreERT2; Pafah1b1hc/hc +TM12 h) (40.5 ± 8.4%) compared with control MEFS (CAGG-CreERT2; Pafah1b1+/− +TM12 h) (13.5 ± 2.4%) (Figure 5E).
Figure 4. Loss of Pafah1b1 in mouse embryonic fibroblasts (MEFs) impairs normal cytokinesis and leads to binucleation of the daughter cells. (A) Pafah1b1 mutant mouse embryonic fibroblasts (MEFs) (Pafah1b1hc/ko) displayed failure of cytokinesis, daughter cell separation, compared with WT MEFs, analyzed by time-lapse live-cell imaging. (B) Increased binucleation by fused daughter cells from MEFs with acutely deleted Pafah1b1 (CAGG-CreERT2; Pafah1b1hc/hc). (C) Increased apoptotic cell death from Pafah1b1hc/ko MEFs compared with WT MEFs (green: cleaved caspase-3, red: α-
Mislocalization of RhoA and contractile ring components in mitosis of Pafah1b1 mutant MEFs

We tested whether critical regulators of cytokinesis contribute to Pafah1b1-deficiency-induced cell membrane hyper-contractility. Since RhoA is an important master GTPase regulating cytokinesis, we examined RhoA localization in Pafah1b1 mutant MEFs fixed with 10% TCA (Yonemura et al., 2004). In WT MEFs, the active forms of RhoA symmetrically accumulated at both sides of the equatorial cortex and were concentrated in the midbody at late telophase and during cytokinesis (Figure 6A). From anaphase to telophase, RhoA colocalized with the cell membrane-associated Anillin, a key component of the contractile ring that defines the cleavage furrow ingresson site. By contrast, 60% of Pafah1b1hc/ko MEFs displayed mislocalization of the cleavage furrow with the formation of large polar blebs in ectopic membrane sites (Figure 6B). An aberrant cleavage furrow was found at only one side of the cell equatorial cortex of Pafah1b1hc/ko MEFs, resulting in asymmetric mislocalization of RhoA and Anillin (Figure 6B, upper panel). The binucleated Pafah1b1hc/ko MEFs displayed protruding polar blebs in ectopic locations (Figure 6B, lower panel). Intriguingly, RhoA immunoreactive signal decorated the cell membrane of all of these polar blebs, suggesting that RhoA and actomyosin may be the primary signals to produce aberrant membrane bulges in Pafah1b1hc/ko MEFs.

Since the LIS1-dynein-dynactin complex is associated with the cortical cell membrane (Faulkner et al., 2000; Moon et al., 2014), it is plausible that cortical dynactin, P150glued, may be less enriched in the cell membrane and cause Anillin mislocalization in Pafah1b1hc/ko MEFs. Cortical P150glued was incorporated within the polar cortex but it was excluded in the cleavage furrow where Anillin was associated with the equatorial cortex in WT MEFs (Figure 6C). However, reciprocal exclusion of polar P150glued vs. equatorial Anillin was less obvious in Pafah1b1hc/ko MEFs (Figure 6D; Moon et al., 2014). From anaphase to telophase, the cells with cleavage furrow-associated Anillin were reduced in Pafah1b1hc/ko MEFs (27.1%) relative to WT control Pafah1b1+/+ MEFs (72.3%) (Figure 6E, in gray).

We found that Pafah1b1-deficient MEFs had mislocalization of a key contractile ring component, Anillin. Hence, we examined cellular localization of LIS1 and Anillin during late stages of mitosis and cytokinesis and evaluated co-localization between LIS1 and Anillin. However, only rabbit-derived antibodies against LIS and Anillin were sufficiently specific in MEFs, so we were not able to perform direct dual immunocytochemistry with combination of LIS1 and Anillin antibodies. When we alternatively traced LIS1 and Anillin antibody separately with α-Tubulin, we found no evidence of substantial overlap of intercellular compartments with LIS1-Anillin in MEFs undergoing late mitosis and cytokinesis. During mitotic division of WT MEFs, LIS1 was localized only to the centrosomes in metaphase-to-anaphase and the central MTs during cytokinesis displaying mostly cytosolic distribution (Figure 7A), while Anillin was initially seen on the lateral cortex and later specifically accumulated in the cytokinetic abscission ring between two central MT bundles, near the equatorial cortex (Figure 7B). These results support that LIS1 may only indirectly regulate Anillin through F-actin cytoskeleton regulation.

Mislocalization of F-actin and myosin II in mitosis of Pafah1b1 mutant MEFs

A previous study demonstrated that the leading process-associated F-actin is misregulated during migration of post-mitotic neurons in Pafah1b1hmor mutants (Kholmanskikh et al., 2003). Actin dysfunction induced by loss of LIS1 may lead to cytokinetic defects and hyper-contractility seen in Pafah1b1hc/ko MEFs. To test this possibility, we co-immunostained MEFs with phalloidin (F-actin zone) and dynein intermediate chain (DIC 74.1). WT MEFs had an F-actin zone located at the...
Figure 5. Loss of Pafah1b1 results in vigorous cell shape oscillation and mitotic spindle rocking that ultimately leads to cytokinetic failure with aberrant cleavage plane positioning. (A) Acutely deleted Pafah1b1 mutant MEFs (CAGG-CreERT2; Pafah1b1^{hc/hc} + TM^{12h}) displayed severe cleavage plane defects during cytokinesis. There was instability of the midbody (highly concentrated with red fluorescence: mCherry-α-Tubulin) accompanied by cell shape oscillation and spindle rocking (green: H2B-GFP). Scale bar: 20 μm. (B) The MEFs with acutely deleted Pafah1b1 displayed abnormal cell shape.
and chromosome oscillation between two daughter cells. Yellow arrow (28°): anucleated one daughter cell, White arrow (36°): binucleated and bi-lobed daughter cell. Scale bar: 10 μm. (C) An increase in the frequency of hyper-contractility phenotype in Pafah1b1hc/ko MEFS. Scale bars: 10 μm. Quantitative data were included in Figure 5-figure source data 1.

Abnormal Myosin II movements during mitosis of Pafah1b1 mutant MEFS

We also monitored actomyosin dynamics by performing time-lapse live-cell imaging of non-muscle myosin regulatory light chain1 (MRLC1)-GFP in MEFS. MRLC1-GFP is a reliable molecular probe to illustrate the localization of the Myosin II (Beach et al., 2011; Miyauchi et al., 2006). We infected MEFS with MRLC1-GFP and H2B-tdTomato retroviruses to visualize Myosin II and chromosomes, respectively. In control MEFS (CAGG-CreERT2; Pafah1b1+/+ + TM, MRLC1 accumulated at the equatorial cortex and the contractile ring, then it constricted normally (Figure 9A, Video 3). By contrast, Cre-inducible Pafah1b1 CKO mutant MEFS (CAGG-CreERT2; Pafah1b1hc/hc + TM, MRLC1) displayed impairments in Myosin II movements (Figure 9B, Video 4).

Cleavage furrow ingression first occurred but regressed abnormally, with failure to restrict the cleavage furrow at the equatorial cortex. Cleavage furrow mispositioning occurred and resulted in chromosome missegregation. Multiple ectopic membrane bulges were found near the polar cortex in Pafah1b1 mutant MEFS, suggesting that aberrant cytoplasmic pushing forces may be generated by ectopically located Myosin II.

In the severely affected cells, Pafah1b1 mutant MEFS displayed an uncoupling between midbody that also colocalized with DIC (Figure 7A, upper panel). By contrast, Pafah1b1hc/ko MEFS had wider F-actin cortical patches at the midzone that extended to the polar cortex in one daughter cell compared with WT MEFS. Central MT-associated F-actin fibers were also evident in Pafah1b1hc/ko MEFS (Figure 7A, lower panel).

We next examined the localization of Myosin II in Pafah1b1hc/ko MEFS relative to WT MEFS. Myosin II is the main molecular motor of the cortical contraction complex of cytokinesis, cooperatively working with the F-actin (Piekny et al., 2005). In WT MEFS, non-muscle myosin heavy chain II A (NMHCIIA) immuno-reactive signal at the spindle midzone overlapped with the F-actin focus zone (Figure 8B, upper panel). By contrast, we found that MHCIIA distribution was diffused and dispersed at the spindle midzone in Pafah1b1hc/ko MEFS (Figure 8B, lower panel). Quantitation of dispersed MHCIIA and F-actin distribution indicated that Pafah1b1hc/ko MEFS had fewer cells with normal cleavage furrow-associated actomyosin patterns (Pafah1b1+/+, 73.4% vs. Pafah1b1hc/ko, 29.7% - in gray). Conversely, Pafah1b1hc/ko MEFS showed an increase in cells with ectopic distribution of actomyosin (Pafah1b1+/+, 26.6% vs. Pafah1b1hc/ko, 70.3% - in red) (Figure 8C). These findings suggest that cortical constriction at the equatorial cortex was impaired in Pafah1b1hc/ko MEFS, leading to mispositioning of the cleavage furrow by actomyosin dysfunction.
chromosome segregation and cytokinesis (Figure 9C, Video 5). In normal cytokinesis, chromosome sets first separated into the two daughters, followed by equatorial constriction to initiate cytokinesis. However, this sequential progression of cytokinesis was disrupted in Pafah1b1 mutant MEFs. Although chromosome sets did not segregate precisely into two daughter cells before the anaphase onset of mitotic spindle elongation, actomyosin-mediated hyper-contractility of the cell membrane triggered cytokinesis progression, producing binucleated cells.

Failure to maintain contractile ring components at the equatorial cortex in Pafah1b1 mutant MEFs
To test whether the actomyosin dysfunction in Pafah1b1 mutant MEFs exert deleterious effects on the recruitment of contractile components to the equatorial cortex, we performed time-lapse live-cell imaging of Septin6 (SEPT6)-GFP (Gilden et al., 2012). Like Anillin, the Septin complex is the key component of the contractile ring during cell cleavage. In control MEFs, SEPT6 was enriched at the equatorial cortex and stayed at the cleavage furrow ingestion site (Figure 10A, Video 6). However, after acute Pafah1b1 deletion in Pafah1b1 CKO mutant MEFs (CAGG-CreERT2; Pafah1b1hc/hc +TM24/2), SEPT6 was initially observed at the equatorial cortex but then it regressed, and weak SEPT6 accumulation was detected at the cell equator accompanied by cortical deformation and chromosome oscillation/rocking (chromosomes were identified as darker spots in the SEPT6-GFP background) (Figure 10B, Video 7). Further live-cell imaging of SEPT6-GFP infected MEFs showed that the frequency of cytokinetic failure with concomitant SEPT6 mislocalization was increased by 4.7-fold in Pafah1b1 mutant MEFs (66.7% in Pafah1b1hc/ko) compared with WT controls (14.3% in Pafah1b1+/+) (Figure 10C). Intercellular cytokinetic bridges and binucleation events resulted from incomplete cytokinesis were observed only from Pafah1b1-deficient mutant MEF, not like WT MEFs. Together, these results indicate that the contractile ring components were not strictly retained at the equatorial cortex, similar to the defective localization of actomyosin, resulting in hyper-contractility and cytokinesis failure in Pafah1b1 mutant MEFs.

Modulation of RhoA hyper-activity in WT and Pafah1b1 mutant MEFs
If RhoA was hyper-activated in Pafah1b1 mutant MEFs, the cells expressing a constitutively active form of RhoA (CA-RhoA) might mimic cytokinesis defects found in the Pafah1b1 mutant MEFs. To test this possibility, WT MEFs were infected with retrovirus encoding human CA-RhoA (CA-RhoA)-GFP fusion protein. As expected, CA-RhoA-GFP-infected WT MEFs (Pafah1b1+/+ + CA-RhoA-GFP) displayed an increased frequency of cytokinesis failure with mislocalization of Anillin, similar to Pafah1b1hc/ko MEFs (Figure 11A). WT MEFs infected with GFP control retrovirus (Pafah1b1+/+ + GFP) displayed normal cytokinesis (Figure 11B).

Since Pafah1b1hc/ko MEFs displayed the mitotic phenotypes resembling RhoA hyper-activity, we hypothesized that inhibition of RhoA by overexpression of a dominant negative form of RhoA (DN-RhoA) may ameliorate cytokinesis defects in Pafah1b1hc/ko MEFs. Pafah1b1hc/ko MEFs infected with retrovirus encoding a human DN-RhoA (DN-RhoA)-GFP fusion protein (Pafah1b1hc/ko + DN-RhoA-GFP) displayed a decreased frequency of cytokinesis defects compared with control MEFs (Pafah1b1hc/ko + GFP) (Figure 11B). These results imply that Pafah1b1hc/ko MEFs displayed hyper-activation of RhoA and inhibition of RhoA that enabled the rescue of cytokinesis defects seen in Pafah1b1hc/ko MEFs.
Figure 6. Pafah1b1 mutant MEFs display mislocalization of RhoA and Anillin, an important contractile ring component. (A) WT MEFs displayed normal cleavage furrow positioning labeled with TCA-fixed RhoA and Anillin co-staining at the equatorial cortex from early anaphase to telophase. (B) Pafah1b1<sup>hc/ko</sup> MEFs displayed mislocalization of RhoA and Anillin. Upper panel: asymmetric cleavage furrow formation. Lower panel: binucleated cells with RhoA-positive aberrant membrane blebs (A,B) (green: RhoA, red: Anillin, blue: DAPI). (C) WT MEFs displayed an Anillin-positive zone in the cell

Discussion

A number of previous studies have demonstrated that LIS1 is required for neuronal migration and the production of the appropriate numbers of post-mitotic neurons that migrate into their functional cortical layers during embryonic brain development (Gambello et al., 2003; Hirotsune et al., 1998; Sasaki et al., 2000; Tsai et al., 2005; Youn et al., 2009; Hippenmeyer et al., 2010). In addition,
Figure 8. Pafah1b1 mutant MEFs show alterations in F-actin focus zone and Myosin II motor localization during the late stages of mitosis. (A) WT MEFs with accumulation of non-muscle myosin heavy chain II-A (NMHCIIA) at the cell equator. Colocalization of staining of NMHCIIA and F-actin (phalloidin)-focusing zone (green: NMHCIIA, red: F-actin, blue: DAPI). (B) Pafah1b1<sup>hc/ko</sup> MEFs displayed dispersed and less-focused actomyosin at the cell equator.

Figure 8 continued on next page
LIS1 plays an important role in mitotic spindle orientation by controlling MTs and dynein complex in the interphase and metaphase of MEFs and neocortical NPCs (Faulkner et al., 2000; Yingling et al., 2008; Moon et al., 2014). However, during late stages of mitosis including cytokinesis, the cellular functions of LIS1 have not been clearly elucidated. Here we provide new evidence that LIS1 plays a crucial role in regulating cleavage plane positioning at late stages of mitosis and cytokinesis during early mouse development. We demonstrated the instructive functions of LIS1 in spindle orientation segregating the cell fate determinants into two daughter cells during mitosis, and LIS1 also regulates RhoA and Anillin-ring localization during cytokinesis. Collectively, this study provides key insights into underlying cellular mechanisms of which Pafah1b1 deficiency leads to impairments in neurogenesis as well as defects in neuronal migration.

Since Pafah1b1^{hc/ko} NPCs display severe mitotic progression perturbation causing cell cycle arrest at prometaphase and metaphase and frequent apoptosis in the neocortex (Gambello et al., 2003; Yingling et al., 2008), we needed to employ genetically manipulated MADM mouse lines to identify the sparsely labeled apical NPCs and daughter cells in Pafah1b1 mutant embryonic brains in vivo. 
Pafah1b1^{hc/ko} NPCs also exhibited severe mitotic defects and it was not possible to culture viable NPCs in vitro. Thus, it was unclear that Pafah1b1 deficiency in NPCs leads to the same or similar cytokinetic phenotypes seen in MEFs in vitro. In the developing mouse brains, neocortical NPCs express specific nuclear transcription factors (such as PAX6, SOX2) to maintain its proliferative capacity and potency to promote neurogenesis. Neocortical NPCs undergo complex basal-to-apical abscission-mediated cytokinetic process in vivo and they also generate one daughter cell with a different fate, a neuron with different lineage depending on the birth date and subtypes of NPCs in regionally specified neocortical domain. By contrast, MEFs only generate two MEFs with symmetric divisions. Despite the different tissue origins of these two distinct cell types (MEFs and NPCs), both MEF and NPC populations share cellular and cytoarchitectural features during cytokinesis. We confirmed that NPCs retain apical RhoA and Anillin localization when they undergo cytokinesis at the ventricular surface where F-actin polarization occurred in vivo. RhoA and Anillin play crucial roles in determining cytokinetic furrow localization by cross-interacting with F-actin and Myosin II at the equatorial cell membrane and the midbody. It appears that RhoA and Anillin-mediated cytokinetic furrow formation is controlled in a similar manner in both MEFs in vitro and apical NPCs in vivo (vRGs). Multiple in vitro studies have highlighted that genetic mutant MEFs are versatile and reliable cell types to investigate cellular mechanisms underlying cytokinetic defects, including those in the developing brain (Janisch et al., 2013; Rosario et al., 2010; Cook et al., 2011; Serres et al., 2012). In genetically targeted MEFs with reduced protein dose (e.g. Kif20b, Plk4, Ect2, and P27), cytokinesis-associated phenotypes were found, including multi-nucleation and centrosome amplification. Therefore, the use of MEFs enabled us to perform long-term live-cell imaging for various analyses that were not possible in NPCs in vitro or in mouse brains in vivo.

These Pafah1b1 mutant MEF studies of late mitosis and cytokinesis using live-cell imaging revealed that LIS1 restricts the cleavage furrow location at the equatorial cortex by inhibiting cell membrane hyper-contractility, demonstrating that LIS1 plays a critical role in cleavage plane specification as well as in actomyosin-mediated cell membrane contractility. We discovered that Pafah1b1 mutant MEFs displayed abnormal cellular phenotypes at late stages of mitosis and cytokinesis, with increased incidence of binucleation and cell death resulted from the failure in cell separation. Cell shape oscillations and chromosome rocking along the mitotic spindles were also evident in Pafah1b1 mutant MEFs, surprisingly similar to those of Anillin-depleted cells (Echard et al., 2004; Kechad et al., 2012; Piekny and Glotzer, 2008; Straight et al., 2003; Zhao and Fang, 2005). Together, these results suggest that Pafah1b1 deficiency in MEFs induces cleavage furrow mispositioning and failure in the recruitment of contractile ring components to the equatorial cortex. Intriguingly, cell shape oscillation and cytokinesis defects were also previously reported in nocodazole-
Figure 9. Myosin-II is abnormally distributed in Pafah1b1 mutant MEFs during late stages of mitosis. (A) WT MEFs displayed normal recruitment of the myosin regulatory light chain 1 (MRLC, green) of Myosin-II subunit at the equatorial cortex during cytokinesis. Dark black spots inside of the cells indicate chromosome sets. (B) Pafah1b1 mutant MEFs (CAGG-CreERT2; Pafah1b1hc/hc + TM24h) infected with MRLC1-GFP (green) and H2B-tdTomato (magenta), displayed cytokinesis failure with an asymmetrically mispositioned cleavage furrow. (C) Pafah1b1 mutant MEFs clearly displayed uncoupling
treated cells (Canman et al., 2003), suggesting that misregulation of either MT or the MT-actomyosin interface at the cell membrane may induce hyper-contractility leading to abnormal membrane contraction in Pafah1b1 mutant MEFs. During cytokinesis, Pafah1b1-dependent cell membrane contractility may be mediated indirectly by the dysregulation of astral MTs reaching to the cell membrane (Moon et al., 2014).

We aimed to identify the molecular mechanisms underlying Pafah1b1-dependent cell membrane contractility of MEFs. Therefore, we examined the distribution of the other proteins defining cleavage furrow formation including RhoA and its downstream effectors, like contractile ring components and actomyosin. We found that RhoA and Anillin were mislocalized in Pafah1b1 mutant MEFs. For instance, RhoA was found in ectopically localized in large polar blebs in Pafah1b1 mutant MEFs. The Myosin II-positive and F-actin focus zone were dispersed at the equatorial cortex or aberrantly located at the polar blebs in Pafah1b1 mutant MEFs. By alternatively tracing MRLC1 and SEPT6, we confirmed that LIS1 defines cleavage plane positioning by dual regulation of actomyosin and contractile ring. Finally, RhoA hyper-activation in WT MEFs phenocopied the cytokinesis defects seen in Pafah1b1 mutant MEFs, and inhibition of RhoA in Pafah1b1 mutant MEFs decreased the cytokinesis defects observed in these MEFs. Thus, these results suggest that LIS1 exerts its function to restrict the cleavage furrow at the equatorial cortex to finely modulate RhoA-Anillin-actomyosin signaling.

Previous Pafah1b1 mutant mouse studies demonstrated that LIS1 modulates GTPase-mediated F-actin dynamics in interphase cells and post-mitotic neurons. For example, Pafah1b1 heterozygous (Pafah1b1^ko/+^) post-mitotic neurons displayed F-actin dysregulation at the leading processes and aberrant GTPase activities of RhoA-Rac1-Cdc42. Similarly, Pafah1b1^ko/+^ MEFs exhibited abnormal hyper-activation of RhoA GTPase (Kholmanskikh et al., 2003). A recent Pafah1b1 knockdown fibroblast study also unraveled F-actin dysfunction and focal adhesion disruption during traction-dependent migration (Jheng et al., 2018). Together, these previous findings indicate that LIS1 may regulate not only MTs but F-actin in migrating phases of multiple cell types. Based on the aberrant cytokinetic phenotypes seen in Pafah1b1 mutant NPCs and MEFs, we now demonstrate that loss of LIS1 results in hyper-activation of RhoA signaling and mislocalization of F-actin and Myosin II that generates hyper-contractility forces ectopically at the polar cortex, which is an abnormal site of cleavage furrow ingresson.

Multiple mouse studies have suggested that RhoA GTPase regulates the integrity of the apical NPC niche, through controlling F-actin at the adherens junction (Cappello et al., 2012; Herzog et al., 2011; Katayama et al., 2011). In accordance with this finding, a study of chick neural tube development indicated that RhoA activity modulation and overexpression of a DN-RhoA similarly altered mitotic spindle orientation of apical NPCs (Roszko et al., 2006). In the present study, we demonstrated that neocortical LIS1 is an important upstream mediator of signaling cascades of RhoA-actomyosin-contractile ring components during cytokinesis of apical NPCs.
NPCs. In mouse apical NPCs, Anillin-ring constriction from the basal to apical side determines the cleavage furrow ingression site in mouse apical NPCs (Kosodo et al., 2008). During cytokinesis of neocortical NPCs, Citron kinase and RhoA colocalize at the apical membrane of NPCs where the cleavage furrow and the midbody are positioned (Di Cunto et al., 2000; Sarkisian et al., 2002). In mice, mutations in Citron kinase alter mitotic spindles and RhoA-mediated neurogenic cytokinesis of apical NPCs. In humans, neocortical NPC phenotypes lead to primary microcephaly and microlissencephaly (Basit et al., 2016; Li et al., 2016; Shaheen et al., 2016; Harding et al., 2016; Gai and Di Cunto, 2017). Furthermore, in addition to Citron kinase and RhoA, three members of Kinesin family, Kif20a, Kif20b, and Kif4 regulate neocortical NPC cytokinesis and mutations of these genes result in reduced cortical size with microcephaly (Janisch et al., 2013; Moawia et al., 2017; Geng et al., 2018). Together, these previous studies suggest that dynamic movements of RhoA and cleavage furrow-associated proteins to the midbody is the key cellular process regulating NPC cytokinesis by precisely segregating cell determinants along the cell cleavage axis.

**Video 4.** Abnormal Myosin II movements during cytokinesis of Pafah1b1 mutant MEFs. Time-lapse live cell imaging of mitotic cell division from Pafah1b1 mutant MEFs (CAGG-CreERT2;Pafah1b1^{flox/flo} +TM^{24} h). Myosin regulatory light chain 1 (MRLC1)-GFP and H2B-tdTomato labeled fluorescence signals were acquired with a 30 s interval by Nikon Ti spinning disk confocal microscope. In Pafah1b1 mutant MEFs, MRLC1 was first recruited to the equatorial cortex. However, we found failure to properly restrict the cleavage furrow at the equatorial cortex.

Figure 10. The contractile ring component SEPT6 is not properly maintained at the equatorial cortex in Pafah1b1 mutant MEFs. (A) WT MEFs displayed normal recruitment of Septin 6 (SEPT6-GFP, in green), an actomyosin-fiber crosslinking protein composed of contractile ring, to the equatorial cortex. (B) Pafah1b1 mutant MEFs (CAGG-CreERT2; Pafah1b1<sup>hc/hc</sup> + TM<sup>24h</sup>) displayed cell shape oscillation with spindle/chromosome rocking. Pafah1b1 mutant MEFs displayed chromosome missegregation and failure to maintain proper contractile ring contraction sites. Dark black
In the developing neocortex, apical NPCs self-renew via symmetric divisions, and produce the major populations of post-mitotic neurons via asymmetric divisions. The orientation of the cleavage plane is thought to be a major regulator of symmetric versus asymmetric cleavage. Our present study suggests that the LIS1-RhoA-actomyosin pathway sets the apical NPC cleavage plane by enrichment of cytokinetic furrow proteins to the ventricular surface, contributing to the later mitotic events when cell fate determinants separate into the daughter cells. Immunohistochemical analyses of the mouse neocortex uncovered that Pafah1b1 mutant NPCs displayed mislocalization of RhoA and Anillin skewed to only one daughter cell, indicating unequal inheritance and this may impact the segregation of cell fate determinants by inducing an imbalance of symmetric versus asymmetric divisions. Consistent with this data, we previously reported that Pafah1b1-deficient E14.5 neocortex had an increase in TUJ1-positive neurons and cleaved caspase-3-positive apoptotic cells (Gambello et al., 2003). This suggests that neocortical daughter cell fates and survival/death are sensitive to LIS1 expression levels in neocortical NPCs. We also demonstrated that Pafah1b1-deficient E15.5 neocortex displayed partial diffuseness and thinning of cortical plate with weak formation of the subplate. In the cortex of postnatal day 5 NPC-specific Pafah1b1 CKO mice (GFAP-Cre;
The Pafah1b1hc/ko also had reduced numbers of upper-layer neurons marked by FOXP1 (Layer III/VI) and CUX1 (Layer II/III) (Youn et al., 2009), indicating that Pafah1b1 deficiency in NPCs leads to impairments in neuronal subtype specification and total neurogenesis accompanied with cortical patterning defects.

In the present study, we observed mitotic phenotypes from apical NPCs, the vRGs, in the E14 neocortex. Pafah1b1 deficiency at earlier time points (E9.5–E11.5) resulted in neural epithelial stem cell death via apoptosis, due to disruption of symmetric mitotic division with vertical cleavage plane, so these earlier stem cells could not be studied. At mid-gestation, we were able to utilize conventional hypomorphic mutants and NPC-specific CKO mutants and circumvented mitotic arrest and...
death mechanisms. E14 vRGs had a sufficient amount of LIS1 to avoid severe mitotic catastrophe and still displayed robust cytokinetic defects with distorted cleavage plane and mitotic spindles.

Our novel findings of LIS1 functions in cytokinesis may explain the mechanism of the recent studies with induced pluripotent stem cells (iPSCs) of Miller Dieker syndrome, a severe form of lissencephaly with haploinsufficiency of PAFAH1B1 as well as about 20 other genes. We demonstrated a prolongation of mitosis of oRG progenitors but not ventricular zone radial glial (vRG) progenitors (Bershteyn et al., 2017). The specificity of mitotic effects in the oRGs and lack of its effects in the vRGs may be the result of different dose dependencies of LIS1 in mouse vs. human, such that LIS1 deficiency results in more prolonged mitotic time specifically in oRGs rather than vRGs. Compared with vRGs, oRG populations lack their endfeet attachment to the apical VZ surface. Intriguingly, human oRGs exhibit rapid mitotic somal translocation toward the cortical plate right before cytokinesis (Hansen et al., 2010). These abrupt movements of human oRGs suggest dynamic cytoskeletal rearrangements during mitotic phases of oRGs. In our current mouse studies, we could not investigate oRG phenotypes due to the low number oRGs present in the neocortices of mice. By contrast, the neocortices of gyrencephalic mammals (from the ferret to primates) contain substantial number of oRGs that exhibit unique mitotic somal translocation, unrestricted mitotic spindle angles, multiple rounds NPC self-renewal and promote expansion of progenitors, neocortical folding and increased topology. Since oRGs highly express a specialized transcriptional factor, HOPX (Pollen et al., 2015) on top of the pan-RG markers PAX6 and SOX2, it would be crucial to investigate the orchestrated crosstalk between HOPX-dependent transcriptional/epigenetic network and actomyosin-mediated cytokinesis in oRGs. In the future, characterization of the localization of diverse protein markers enriched to the cleavage furrow in human or primate iPSC-derived NPCs and fetal neocortical NPCs, such as RhoA, Anillin, and Citron kinase of NPCs, will need to be analyzed to better understand the oRG-specific sensitivity to LIS1 dosage especially in human. It would also be interesting to determine whether other lissencephaly or brain malformation-associated genes modulate RhoA-Anillin-actomyosin-pathways, and to test whether these genes, like LIS1, also possess dual roles in actomyosin and MT regulation important for apical NPCs by controlling key cellular processes not only mitosis but cytokinesis, a critical final step of cell determinant segregation.

**Animals**

The mouse lines used in the present study were previously described; CAGG-CreERT2 (Hayashi and McMahon, 2002), Pafah1b1\(^{hcr}\), Pafah1b1\(^{hcr}\) and Pafah1b1\(^{hcr}\) (Yingling et al., 2008; Moon et al.,...
All animal care and experimental procedures (Protocol ID: AN085137-02A) were approved by the University of California, San Francisco Institutional Animal Care and Use Committee (IACUC) in accordance with the National Institutes of Health Guide for the Care and Use of Laboratory Animals.

**Cell culture and immunocytochemistry**

Primary MEFs cell culture was performed as previously described Moon et al. (2014). Cre recombinase in CAGG-CreERT2-MEFs was induced by administration of 4-hydroxy tamoxifen (TM) (Sigma, 100 nM) for 12 hr. DMSO and blebbistatin (Calbiochem, 100 μM) were used to treat MEFs for 30 min. To identify RhoA in the cortex and cleavage furrow, MEFs were fixed with freshly made 10% trichloroacetic acid (TCA) for 10 min (Yonemura et al., 2004). Immunocytochemistry staining of cortical P150−Glued, was performed in 100% methanol-fixed samples as previously described Moon et al. (2014). The antibodies used in this study were listed in Key Resources Table.

**Retrovirus infection, epifluorescence and spinning-disk confocal live-cell imaging**

Time-lapse live-cell imaging of MEFs infected with retroviruses encoding H2B-GFP, mCherry-α-Tubulin was described previously Moon et al. (2014). To induce Cre-mediated Pafah1b1 CKO allele deletion, the MEFs derived from CAGG-CreERT2; Pafah1b1<sup>+/+;</sup> and CAGG-CreERT2; Pafah1b1<sup>hc/hc</sup> animals were treated with 4-hydroxy-tamoxifen (TM) (Sigma, 100 nM) for 12 hr or 24 hr. To visualize Myosin II movements during cytokinesis, primary MEFs were co-infected with a mixture of MRLC1-GFP and H2B-tdTomato retroviruses with 4 μg/mL polybrene. Lasers with 488 nm and 561 nm emission were used for GFP and tdTomato imaging. SEPT6-GFP was also traced by a Nikon Ti spinning-disk confocal microscope with a 488 nm emission laser. The sequential 2 μm interval 5~7 Z-stack images were captured every 30 s. The best Z confocal plane images showing the cleavage furrow were made as time-lapse movies. The plasmid sources of retrovirus construction were described in Key Resources Table.

**Immunohistochemistry**

Mouse fetal brains were isolated from E14.5 embryos described in Yingling et al. (2008) followed by fixation with 4% paraformaldehyde (PFA) or 10% TCA (RhoA staining). On the next day, the brains were transferred to 30% sucrose and embedded in O.C.T. compound to make cryomolds. 18 μm-thick cryostat sections of neocortex were used for immunohistochemistry. In MADM-11 animals, we identified Lis1 genotype based on GFP or tdT immunoreactivity. Cleavage furrow markers such as Anillin and RhoA were immunostained in the far-red Alexa Fluor 647 channel to separate the fluorescence signal from GFP and tdT. Anillin- or RhoA-immunoreactive signals were pseudo-colored in green for representation purpose. The antibodies used in this study were listed in Key Resources Table.

**Sample size, Replicates, and Statistical analysis**

Time-lapse live-cell imaging of primary MEFs was performed and data analyses were conducted from at least three independent experimental sets. Sample-size from live-cell imaging for data analysis was calculated based on empirical sample-size previously tested from mitotic analysis of Pafah1b1 mutant MEF study (Moon et al., 2014). In all MEF live-cell imaging experiments, the exact cell number recorded for monitoring whole duration of mitotic cellular division (from prometaphase to telophase/cytokinesis) were written in Source data files. From the fixed samples for immunohistochemistry using the embryonic brains, the exact number of cells taken for confocal images of apical NPCs located at the ventricular zone was recorded in Source data files. In immunocytochemistry analysis of MEFs, the exact sample number of cells for taking confocal images was recorded in Source data files. No data points were excluded for statistical analysis and all raw data points were included. Two-tailed Student’s t-test was used to compare mitotic cellular phenotypes and to evaluate statistical significance and differences between controls and Pafah1b1 mutant groups. *p<0.05, **p<0.01, ***p<0.001, ns: not significant. Bars in the graphs with error bars represented: mean ± S.E.M.
Acknowledgements

We would like to thank Dr. Arshad Desai and Dr. Karen Oegema in UCSD for providing initial key insights into the novel phenotypes seen in Lis1 mutant MEFs, Dr. Torsten Wittmann, Hayley Pemble, Kurt Thorn at Nikon imaging center in UCSF for access to microscopes for time-lapse live-cell imaging, Dr. Matthew Krummel in UCSF for Septin6-GFP plasmid, Dr. Kozo Kaibuchi in Nagoya University for RhoA plasmids and insightful advice, and Dr. Giles Plant in Stanford University for access to Nikon imaging analysis.

Serres MP, Kossatz U, Chi Y, Roberts JM, Malek NP, Besson A. 2016. The syndrome dysmorphic facies, renal agenesis, and genitalia, microcephaly, polydactyly and lissencephaly (DREAM-PL): Report of two additional patients. *Human Molecular Genetics* **25**:I60376, PMID: 22293177

Shaheen R, Sarkisian MR, Al-Salam Z, El-Hattab AW, Alkuraya FS. 2016. The syndrome dysmorphofacies, renal agenesis, ambiguous genitalia, microcephaly, polydactyly and lissencephaly (DREAM-PL): Report of two additional patients. *American Journal of Medical Genetics Part A* **170**:3222–3226. DOI: https://doi.org/10.1002/ajmg.a.37877, PMID: 27480277

Sassone-Corsi P, Masiello F, Cho J, Masiello M, Sachidananda S, Tomoyasu Y, et al. 2000. The Drosophila protein Radish is essential for cell proliferation and mitotic spindle assembly in vivo. *Science* **290**:1743–1747. DOI: https://doi.org/10.1126/science.1081412, PMID: 12637748

Tsai JW, Chen Y, Kriegstein AR, Vallee RB. 2005. LIS1 RNA interference blocks neural stem cell division, Morphogenesis, and motility at multiple stages. *The Journal of Cell Biology* **170**:935–945. DOI: https://doi.org/10.1083/jcb.200505166, PMID: 16144905

van Dassow G. 2009. Concurrent cues for cytokinetic furrow induction in animal cells. *Trends in Cell Biology* **19**:165–173. DOI: https://doi.org/10.1016/j.tcb.2009.01.008, PMID: 19285868

Watanabe S, Ando Y, Yasuda S, Hosoya H, Watanabe N, Ishizaki T, Narumiya S. 2008. mDia2 induces the actin scaffold for the contractile ring and stabilizes its position during cytokinesis in NIH 3T3 cells. *Molecular Biology of the Cell* **19**:2328–2338. DOI: https://doi.org/10.1091/mbc.e07-10-1086, PMID: 18287523

Werner M, Munro E, Glotzer M. 2007. Astral signals spatially Bias cortical myosin recruitment to break symmetry and promote cytokinesis. *Current Biology* **17**:1286–1297. DOI: https://doi.org/10.1016/j.cub.2007.06.070, PMID: 17669650

Werner M, Glotzer M. 2008. Control of cortical contractility during cytokinesis. *Biochemical Society Transactions* **36**:371–377. DOI: https://doi.org/10.1042/BST0360371, PMID: 18481961

Wynne CL, Vallee RB. 2018. Cdk1 phosphorylation of the dynein adapter Nde1 controls cargo binding from G2 to anaphase. *The Journal of Cell Biology* **217**:3019–3029. DOI: https://doi.org/10.1083/jcb.201707081, PMID: 29930206

Yingling J, Youn YH, Darling D, Toyo-Oka K, Pramparo T, Hirotsune S, Wynshaw-Boris A. 2008. Neuroepithelial stem cell proliferation requires LIS1 for precise spindle orientation and symmetric division. *Cell* **132**:474–486. DOI: https://doi.org/10.1016/j.cell.2008.01.026, PMID: 18267077
Yonemura S, Hirao-Minakuchi K, Nishimura Y. 2004. Rho localization in cells and tissues. *Experimental Cell Research* **295**:300–314. DOI: https://doi.org/10.1016/j.yexcr.2004.01.005, PMID: 15093731

Youn YH, Pramparo T, Hirotsune S, Wynshaw-Boris A. 2009. Distinct dose-dependent cortical neuronal migration and neurite extension defects in Lis1 and Ndel1 mutant mice. *Journal of Neuroscience* **29**:15520–15530. DOI: https://doi.org/10.1523/JNEUROSCI.4630-09.2009, PMID: 20007476

Zhao WM, Fang G. 2005. Anillin is a substrate of Anaphase-promoting complex/Cyclosome (APC/C) that controls spatial contractility of myosin during late cytokinesis. *The Journal of Biological Chemistry* **280**:33516–33524. DOI: https://doi.org/10.1074/jbc.M504657200, PMID: 16040610

Zhou M, Wang YL. 2008. Distinct pathways for the early recruitment of myosin II and actin to the cytokinetic furrow. *Molecular Biology of the Cell* **19**:318–326. DOI: https://doi.org/10.1091/mbc.e07-08-0783, PMID: 17959823

Zhao L, Theis M, Alvarez-May I, Brenner M, Willecke K, Messing A. 2001. hGFAP-cre transgenic mice for manipulation of glial and neuronal function in vivo. *Genesis* **31**:85–94. DOI: https://doi.org/10.1002/gene.10008, PMID: 11668683
