Abstract

An adiabatic approximation to the selfconsistent collective coordinate method is formulated in order to describe large amplitude collective motions in superconducting nuclei on the basis of the time-dependent Hartree-Fock-Bogoliubov equations of motion. The basic equations are presented in a local harmonic form which can be solved in a similar way as the quasiparticle RPA equations. The formalism guarantees the conservation of nucleon number expectation values. An extension to the multi-dimensional case is also discussed.
I. INTRODUCTION

Large amplitude collective motions (LACM), such as fissions, shape transitions, anharmonic vibrations and low energy heavy ion reactions, are often encountered in the studies of nuclear structures and reactions. To go beyond the phenomenological models assuming some macroscopic or collective degrees of freedom motivated by the experimental facts and intuitions, many attempts have been made to construct theories that are able to describe the LACM on a microscopic basis of the nuclear many-body Hamiltonian. Especially, theories based on the time-dependent Hartree-Fock (TDHF) approximation have been investigated extensively \[1\]-\[3\]. The TDHF is a general framework for describing low energy nuclear dynamics accompanying evolution of the nuclear selfconsistent mean-field \[7\]-\[8\]. A LACM corresponds to a specific solution of the TDHF equation of motion. Since such a solution forms only a subset of the whole TDHF states (Slater determinants), it is often called a collective path, a collective subspace, or a collective submanifold. The collective coordinates are then a set of small number of variables that parameterize the collective subspace, and the collective Hamiltonian is a function governing the time evolution of the collective coordinates. One of the main purposes of the LACM theories is to provide a scheme to determine the collective subspace and the collective Hamiltonian on the basis of microscopic many-body Hamiltonian. Although the studies of LACM theories are the vast field of research with many recent developments to different directions, realistic applications to nuclear structure problems are rather limited. In this paper, we would like to propose a new practical method to calculate the collective subspace.

The adiabatic approximation has been often utilized for formulating the theory of collective subspace. Indeed, some class of LACM, such as nuclear fissions, can be regarded as a slow motion, thus justifying the adiabatic approximation. The adiabatic TDHF (ATDHF) theory \[1\]-\[3\] is one of the most well known adiabatic theories and has been applied in some cases to realistic description of heavy ion reactions \[8\]. The ATDHF theory, however, accompanied a problem of non-uniqueness of the solution \[8\]. Later, efforts to settle the non-uniqueness problem were made from different view points. The works of Ref. \[8\] emphasize the importance of the canonical variable condition and the analyticity as a function of collective coordinate for finding a unique solution. The proposed procedure relying on the Taylor expansion method has not been applied to realistic calculations. Another work \[8\] pointed out that the collective subspace can be uniquely determined by using the next order equation of the ATDHF theory. It is clarified also that the adiabatic collective path of LACM becomes the valley line of the potential function in the multi-dimensional space associated with the TDHF states \[7\]-\[8\]. Further, the adiabatic collective path can be defined by equations for a local harmonic mode at each point of the collective path. These developments are summarized in a consistent way in the formalism of Ref. \[8\]. Note however that the adiabatic theory of Ref. \[8\] relies on a multi-dimensional classical phase space representation of the TDHF determinantal states \[7\]-\[8\]. A realistic application of this theory has not been done yet except for the one to a light nucleus \[14\]. Furthermore a problem of particle number conservation arises when applied to superconducting nuclei \[14\].

Theories without the adiabatic approximation have been also developed within the TDHF framework. The early works of this direction are called local harmonic approximations \[12\]-\[13\]. Later, a set of general equations that can determine the collective subspace and the collective Hamiltonian were found and formulated in a consistent form known as the selfconsistent collective coordinate method (SCC or SCCM) \[14\]. The theory is purely based on the TDHF with no further approximation. The method also provides a concrete and practical scheme to solve the basic equations using a power series expansion with respect to the boson-like variables defined as a linear combination of the collective coordinates and momenta. The pairing correlation in superconducting nuclei is easily incorporated within the SCCM by adopting the time-dependent Hartree-Fock-Bogoliubov (TDHFB) equation in place of the TDHF, and the conservation law of the particle number is consistently introduced in the basic framework of the SCCM \[14\]. Thanks to these features the SCCM has been applied for many realistic descriptions of anharmonic vibrations in medium and heavy nuclei \[14\]. However, the expansion method may not be suitable for the large amplitude motions of adiabatic nature, for which change of the nuclear mean-field is so large that the power series expansion of the collective coordinates may not be justified.

In the present paper, we try to combine merits of two approaches mentioned above, i.e. the SCCM and the adiabatic theory in order to formulate a theory that provides a consistent and practical method easily applicable to realistic descriptions of the adiabatic LACM in superconducting nuclei. We achieve this aim by introducing an adiabatic approximation to the general framework of SCCM. Here we treat superconducting nuclei since the pairing correlations play essential roles in many cases, like spontaneous fission, tunneling between superdeformed and normal deformed configurations, and coupling between coexisting states with different nuclear shape (shape coexistence phenomena). Although the use of the superconducting mean field
requires us to respect the particle number conservation, the SCCM allows a simple and consistent treatment of the conservation law. We also avoid the non-uniqueness problem by utilizing the principles similar to that of Refs. [6, 7]. Furthermore, we shall show that the equations of the adiabatic SCCM thus formulated can be transformed to another set of equations that have a similar structure as the local harmonic approach to the adiabatic theories [8]. Therefore, the present formalism is not only an extension of the SCCM, but also succeeds some aspects of the recent adiabatic theories such as Ref. [8].

In addition to the general formulation (Sect. II), we present a practical scheme to solve the basic equations given in the local harmonic form for general classes of the many-body nuclear Hamiltonian (Sect. III and Appendix). These equations are given in terms of the matrix elements of the many-body Hamiltonian expressed by the quasiparticle operators, thus enabling ones to develop a straightforward coding of a numerical program to solve the equations. In this way, we provide a complete procedure to extract the collective subspace and the collective Hamiltonian. We also discuss a possible prescription to extend the formalism to the cases of the multi-dimensional collective motions (Sect. IV). Conclusions are outlined in Sect. V.

II. BASIC EQUATIONS

A. The SCC method for superconducting nuclei

In this subsection, we recapitulate the basic equations of the SCC method [14] in a way suitable for treating the superconducting nuclei. We introduce the TDHFB approximation to describe LACM in superconducting many-fermion systems. Here the time-dependent many-body state vector $|\phi(t)\rangle$ is constrained to a generalized Slater determinant, which is chosen as a variational wave function. Time evolution of $|\phi(t)\rangle$ is then determined by the time-dependent variational principle

$$
\delta \langle \phi(t)| i \frac{\partial}{\partial t} - \hat{H} |\phi(t)\rangle = 0,
$$

where the variation is given by $\delta |\phi(t)\rangle = a^\dagger_\alpha a^\dagger_\beta |\phi(t)\rangle$ in terms of the quasiparticle operators $\{a_\alpha^\dagger, a_\alpha\}$ which satisfy the vacuum condition $a_\alpha |\phi(t)\rangle = 0$.

We assume that the LACM can be described in terms of the collective variables, i.e. the collective coordinate and momentum $\{q, p\}$ that are variables parameterizing the TDHFB state vector. The whole space of the TDHFB state vectors can be parameterized by $M \times (M - 1)$ variables ($M$ being the number of the single particle states) as shown by the generalized Thouless theorem [15,16]. A set of the TDHFB state vector $|\phi(q, p)\rangle$ forms the collective subspace in which the LACM can be properly described. One of the main problems we concern is how to determine the collective subspace on the basis of the TDHFB equations of motion. At the same time, we need to determine the collective Hamiltonian $H(q, p)$ that governs the equation of motion for the collective variables $\{q, p\}$. This is a general purpose of theories of LACM.

When we apply the LACM theories to nuclei in the superconducting phase, a special attention has to be paid to the particle number conservation. Since the TDHFB state vector is not an eigenstate of the particle number operator $\hat{N}$, one would like to formulate the LACM theory so that the particle number expectation value is conserved during the course of collective motion. This is a problem which is specific to the TDHFB, but not to TDHF for which the state vector is a number eigenstate.

It is well known [17] that the expectation value of a conserved observable is kept constant during the time-evolution of $|\phi(t)\rangle$ governed by the TDHF(B) equations of motion. In the case of the pairing problem, the TDHFB state vector violates spontaneously the symmetry with respect to the gauge rotation $e^{-i\varphi \hat{N}}$, but a rotational motion related to the gauge rotation (often called the pairing rotation) emerges automatically to restore the gauge symmetry. Therefore, the LACM of superconducting nuclei, described by the TDHFB theory, necessarily accompany the pairing rotation, for which we introduce the collective coordinate, $\varphi$, the gauge angle, and the conjugate collective momenta, $N$, which represents the particle number [18]. Thus,

* We focus our discussion on a case of single collective coordinate. A multi-dimensional case is discussed in Sect. IV.
we are obliged to consider a collective subspace that is parameterized by the set of four collective variables \( \{ q, p, \varphi, N \} \).

Let us now present the basic equations of the SCCM that determine the collective subspace \( |\phi(q, p, \varphi, N)\rangle \) and the collective Hamiltonian \( \mathcal{H}(q, p, \varphi, N) \). As discussed above, the variable \( \varphi \) is introduced to represent the gauge angle. This requirement is easily satisfied if one uses the following parameterization

\[
|\phi(q, p, \varphi, N)\rangle = e^{-i\varphi N} |\phi(q, p, N)\rangle, \tag{2}
\]

where \( \hat{N} \) is the number operator of particles. Here \( |\phi(q, p, N)\rangle \) represents an intrinsic state that rotates in the gauge space.

Basic equations of the SCCM consists of a canonical variable condition and invariance principle of the time-dependent Schrödinger equation (TDHFB equation in our case). The canonical variable condition is, in general, given by

\[
\langle \phi(q, p, \varphi, N) | i \frac{\partial}{\partial q} | \phi(q, p, \varphi, N) \rangle = p + \frac{\partial S}{\partial q}, \tag{3a}
\]

\[
\langle \phi(q, p, \varphi, N) | \frac{\partial}{\partial p} | \phi(q, p, \varphi, N) \rangle = -\frac{\partial S}{\partial p}, \tag{3b}
\]

\[
\langle \phi(q, p, \varphi, N) | i \frac{\partial}{\partial \varphi} | \phi(q, p, \varphi, N) \rangle = N + \frac{\partial S}{\partial \varphi}, \tag{3c}
\]

\[
\langle \phi(q, p, \varphi, N) | \frac{\partial}{\partial N} | \phi(q, p, \varphi, N) \rangle = -\frac{\partial S}{\partial N}, \tag{3d}
\]

for the collective subspace parameterized by two sets of coordinates \( \{ q, \varphi \} \) and momenta \( \{ p, N \} \). Although \( S \) is an arbitrary function of \( \{ q, p, \varphi, N \} \), we choose \( S = 0 \) which is appropriate for the adiabatic approximation. Then the canonical variable condition can be rewritten as equations for the state \( |\phi(q, p, N)\rangle \),

\[
\langle \phi(q, p, N) | i \frac{\partial}{\partial q} | \phi(q, p, N) \rangle = p, \tag{4a}
\]

\[
\langle \phi(q, p, N) | \frac{\partial}{\partial p} | \phi(q, p, N) \rangle = 0, \tag{4b}
\]

\[
\langle \phi(q, p, N) | N | \phi(q, p, N) \rangle = N, \tag{4c}
\]

\[
\langle \phi(q, p, N) | \frac{\partial}{\partial N} | \phi(q, p, N) \rangle = 0. \tag{4d}
\]

The third equation requires that the collective variable \( N \) is identical to the expectation value of the number operator. In other words, the particle number expectation value does not depend on the collective variables \( \{ q, p \} \) for the LACM under consideration. This is nothing but the condition of particle number conservation.

The collective Hamiltonian is defined as value of the total energy on the collective subspace, given by

\[
\mathcal{H} = \langle \phi(q, p, \varphi, N) | \hat{H} | \phi(q, p, \varphi, N) \rangle = \langle \phi(q, p, N) | \hat{H} | \phi(q, p, N) \rangle. \tag{5a}
\]

Since the Hamiltonian \( \hat{H} \) commutes with the number operator \( \hat{N} \), the collective Hamiltonian does not depend on the gauge angle \( \varphi \). Therefore, \( \varphi \) becomes cyclic as we expect.

The invariance principle of the TDHFB equation plays a central role to determine the collective subspace, which requires that the TDHFB state vector \( |\phi(q(t), p(t), \varphi(t), N(t))\rangle \) evolving in time within the collective subspace should obey the full TDHFB equation, Eq.(4). This is equivalent to a condition that the collective subspace is an invariant subspace of the TDHFB equations of motion. Inserting Eq.(3) into the time-dependent variational principle, Eq.(4), one obtains

\[\text{† For simplicity, here we assume a single kind of particles. Extension to systems with many kinds (e.g., protons and neutrons in nuclei) is straightforward.}\]
\[ \delta \langle \phi(q,p,N) | \hat{H} - \frac{dq}{dt} \hat{P} + \frac{dp}{dt} \hat{Q} + \frac{dN}{dt} \hat{\Theta} - \frac{d\varphi}{dt} \hat{\mathcal{N}} | \phi(q,p,N) \rangle = 0, \]  

(6)

where the infinitesimal generators defined by

\[ \hat{P} |\phi(q,p,N)\rangle = i \frac{\partial}{\partial q} |\phi(q,p,N)\rangle, \]
\[ \hat{Q} |\phi(q,p,N)\rangle = \frac{1}{i} \frac{\partial}{\partial p} |\phi(q,p,N)\rangle, \]
\[ \hat{\Theta} |\phi(q,p,N)\rangle = \frac{1}{i} \frac{\partial}{\partial N} |\phi(q,p,N)\rangle \]

(7a, 7b, 7c)

are used. These operators are one-body operators which can be written as linear combinations of bilinear products \( \{ a^\dagger_\alpha a_\beta, a_\beta a_\alpha, a^\dagger_\alpha a^\dagger_\beta \} \) of the quasiparticle operators defined with respect to \( |\phi(q,p,N)\rangle \). Because of the canonical variable conditions, these infinitesimal generators satisfy the following commutation relations

\[ \langle \phi(q,p,N) | [\hat{Q}, \hat{P}] |\phi(q,p,N)\rangle = i, \]
\[ \langle \phi(q,p,N) | [\hat{\Theta}, \hat{\mathcal{N}}] |\phi(q,p,N)\rangle = i, \]

(8a, 8b)

and commutators of other combinations of \( \hat{Q}, \hat{P}, \hat{\Theta}, \hat{\mathcal{N}} \) give zero expectation value. By taking the variation as \( \delta |\phi(q,p,N)\rangle = \{ \hat{P}, \hat{Q}, \hat{\Theta}, \hat{\mathcal{N}} \} |\phi(q,p,N)\rangle \), Eq.(6) produces the canonical equations of motion for the collective variables

\[ \frac{dq}{dt} = \frac{\partial \mathcal{H}}{\partial p} = i \langle \phi(q,p,N) | [\hat{H}, \hat{Q}] |\phi(q,p,N)\rangle, \]
\[ \frac{dp}{dt} = -\frac{\partial \mathcal{H}}{\partial q} = i \langle \phi(q,p,N) | [\hat{H}, \hat{P}] |\phi(q,p,N)\rangle, \]
\[ \frac{d\varphi}{dt} = \frac{\partial \mathcal{H}}{\partial N} = i \langle \phi(q,p,N) | [\hat{H}, \hat{\Theta}] |\phi(q,p,N)\rangle, \]
\[ \frac{dN}{dt} = -\frac{\partial \mathcal{H}}{\partial \varphi} = 0. \]

(9a, 9b, 9c, 9d)

Using Eq.(9), Eq.(10) then reduces to an equation of collective subspace

\[ \delta \langle \phi(q,p,N) | \hat{H} - \frac{\partial \mathcal{H}}{\partial p} \hat{P} - \frac{\partial \mathcal{H}}{\partial q} \hat{Q} - \frac{\partial \mathcal{H}}{\partial N} \hat{\mathcal{N}} |\phi(q,p,N)\rangle = 0. \]

(10)

If we take a variation \( \delta_{\perp} \) that is orthogonal to the infinitesimal generators \( \{ \hat{P}, \hat{Q}, \hat{\Theta}, \hat{\mathcal{N}} \} \), one can immediately show \( \delta_{\perp} \langle \phi(q,p,N) | \hat{H} |\phi(q,p,N)\rangle = 0 \), which implies that the energy expectation value is stationary on the collective subspace for all the variations except for the tangent directions along the collective subspace. In other words, the collective mode is decoupled from the other modes of excitation.

We remark here that the above basic equations of the SCCM are invariant under point transformations of the collective coordinate

\[ q \to q' = q'(q), \]
\[ p \to p' = p \times (\partial q' / \partial q)^{-1}. \]

(11a, 11b)

The basic principles, i.e. the canonical variable condition, Eq.(3), and the invariance principle of the TD-HFB equation, Eq.(2), are not affected by the general canonical transformations of collective variables \( \{ q, p, \varphi, N \} \to \{ q', p', \varphi', N' \} \). By taking the parameterization, Eq.(2), and the specific choice of \( S = 0 \) in Eq.(3), the allowed canonical transformations are restricted to the point transformations \( \Theta_{\perp} \).

**B. Adiabatic approximation**

Assuming that the LACM described by the collective variables \( \{ q, p \} \) is slow motion, we here introduce the adiabatic approximation to the SCCM. Namely we shall expand the basic equations with respect to the collective momentum \( p \), which is appropriate for small value of momentum. Since the particle number
variable $N$ is a momentum variable in the present formulation, we also expand the basic equations with respect to $n = N - N_0$, when we consider a system with particle number $N_0$.

Let us first consider the expansion of the TDHF state vector $|\phi(q, p, N)\rangle$ in the collective subspace. The origin of the expansion is the state $|\phi(q)\rangle \equiv |\phi(q, p, N)\rangle|_{p=0, N=N_0}$. We can assume that this is a time-even state, i.e., $\mathcal{T} |\phi(q)\rangle = |\phi(q)\rangle$ under the time-reversal operation $\mathcal{T}$ (Here we consider the system of even numbers of particles). Thanks to the generalized Thouless theorem, the state vector $|\phi(q, p, N)\rangle$ is expressed as

$$
|\phi(q, p, N)\rangle = e^{i\hat{G}(q, p, n)}|\phi(q)\rangle
$$

by using the unitary transformation $e^{i\hat{G}(q, p, n)}$. Here the hermitian operator $\hat{G}$ is given by

$$
\hat{G}(q, p, n) = \sum_{\alpha>\beta} (G_{\alpha\beta}(q, p, n)a_\alpha^\dagger a_\beta^\dagger + G_{\alpha\beta}^*(q, p, n)a_\beta a_\alpha) = \hat{G}(q, p, n)^\dagger.
$$

Here and hereafter, the quasiparticle operators $\{a_\alpha^\dagger, a_\alpha\}$ are always defined locally at each value of $q$ and satisfy the condition $a_\alpha |\phi(q)\rangle = 0$. We now expand the operator $\hat{G}(q, p, n)$ in powers of $p$ and $n$ and keep only the lowest order term. Namely,

$$
\hat{G}(q, p, n) = p\hat{Q}(q) + n\hat{\Theta}(q),
$$

$$
\hat{Q}(q) = \sum_{\alpha>\beta} (Q_{\alpha\beta}(q)a_\alpha^\dagger a_\beta + Q_{\alpha\beta}^*(q)a_\beta a_\alpha) = \hat{Q}(q)^\dagger,
$$

$$
\hat{\Theta}(q) = \sum_{\alpha>\beta} (\Theta_{\alpha\beta}(q)a_\alpha^\dagger a_\beta + \Theta_{\alpha\beta}^*(q)a_\beta a_\alpha) = \hat{\Theta}(q)^\dagger.
$$

If we require that time-reversal of $|\phi(q, p, N)\rangle$ causes sign inversion of the collective momentum $p$, i.e. $\mathcal{T} |\phi(q, p, N)\rangle = |\phi(q, -p, N)\rangle$, the operators $\hat{Q}(q)$ and $\hat{\Theta}(q)$ are time-even ($\mathcal{T} \hat{Q}(q)\mathcal{T}^{-1} = \hat{Q}(q)$) and time-odd ($\mathcal{T} \hat{\Theta}(q)\mathcal{T}^{-1} = -\hat{\Theta}(q)$), respectively. If we put $n = 0$ (i.e. $N = N_0$), the parameterization Eq.12 together with Eq.14 reduces to $|\phi(q, p)\rangle = e^{i\hat{Q}(q)}|\phi(q)\rangle$, which is the same form as the one introduced by Villars and often used in the ATDHF theories.

The collective Hamiltonian is expanded as

$$
\mathcal{H}(q, p, N) = V(q) + \frac{1}{2}B(q)p^2 + \lambda(q)n,
$$

$$
V(q) = \mathcal{H}(q, p, N)|_{p=0, N=N_0} = \langle \phi(q) | \hat{H} | \phi(q) \rangle, \quad \text{Eq. (15a)}
$$

$$
B(q) = \frac{1}{2}\frac{\partial^2 \mathcal{H}(q, p, N)}{\partial p^2}|_{p=0, N=N_0} = -\langle \phi(q) | [[\hat{H}, \hat{Q}(q)], \hat{Q}(q)] | \phi(q) \rangle, \quad \text{Eq. (15b)}
$$

$$
\lambda(q) = \frac{\partial \mathcal{H}(q, p, N)}{\partial N}|_{p=0, N=N_0} = \langle \phi(q) | [\hat{H}, i\hat{\Theta}(q)] | \phi(q) \rangle, \quad \text{Eq. (15c)}
$$

where we kept the collective momentum $p$ up to the second order, while up to the first order in $n$. The collective Hamiltonian for the system with $N = N_0$ particles ($n = 0$) is given by

$$
\mathcal{H}(q, p, N_0) = V(q) + \frac{1}{2}B(q)p^2
$$

as the sum of the collective potential $V(q)$ and the collective kinetic energy (the second term).

We next expand the infinitesimal generators. It is convenient for this purpose to define the unitary transformation $\hat{P}' = e^{-i\hat{G}}\hat{P} e^{i\hat{G}}$, $\hat{Q}' = e^{-i\hat{G}}\hat{Q} e^{i\hat{G}}$, $\hat{\Theta}' = e^{-i\hat{G}}\hat{\Theta} e^{i\hat{G}}$ of the infinitesimal generators $\hat{P}, \hat{Q}, \hat{\Theta}$. They are expanded as

$$
\hat{P}' = \hat{P}(q) + e^{-i\hat{G}} i \frac{\partial}{\partial q} e^{i\hat{G}} = \hat{P}(q) - p\frac{\partial \hat{Q}}{\partial q} - n\frac{\partial \hat{\Theta}}{\partial q} + \ldots,
$$

$$
\hat{Q}' = e^{-i\hat{G}} \frac{\partial}{\partial p} e^{i\hat{G}} = \hat{Q}(q) + \frac{i}{2}[\hat{Q}, p\hat{P} + n\hat{\Theta}] + \ldots,
$$

$$
\hat{\Theta}' = e^{-i\hat{G}} \frac{\partial}{\partial N} e^{i\hat{G}} = \hat{\Theta}(q) + \frac{i}{2}[\hat{\Theta}, p\hat{Q} + n\hat{\Theta}] + \ldots.
$$
with use of the general expansion formula
\[ e^{-i\hat{G}} \partial e^{i\hat{G}} = i \partial \hat{G} + \frac{1}{2!} [[i \partial \hat{G}, i \hat{G}]] + \frac{1}{3!} [[i \partial \hat{G}, i \hat{G}, i \hat{G}]] + ... \]  
(20)

The operator \( \hat{P}(q) \) is the infinitesimal generator with respect to \( |\phi(q)\rangle \) defined by
\[ \hat{P}(q) |\phi(q)\rangle = i \frac{\partial}{\partial q} |\phi(q)\rangle. \]  
(21)

Similarly, we introduce the unitary transformation of the number operator and expand it as
\[ \hat{N}' \equiv e^{-i\hat{G}} \hat{N} e^{i\hat{G}} = \hat{N} + i[\hat{N}, \hat{P}(\hat{q}) + n\hat{\Theta}] + ... \]  
(22)

Substituting these operators in the canonical variable condition, Eq.(4), we have
\[ \langle \phi(q) | \hat{P}'(q, p, N) |\phi(q)\rangle = p, \]  
(23a)
\[ \langle \phi(q) | \hat{Q}'(q, p, N) |\phi(q)\rangle = 0, \]  
(23b)
\[ \langle \phi(q) | \hat{\Theta}'(q, p, N) |\phi(q)\rangle = 0, \]  
(23c)
\[ \langle \phi(q) | \hat{N}'(q, p, N) |\phi(q)\rangle = N. \]  
(23d)

Now we expand these equations with respect to momentum \( p \) and \( n \).

The zeroth order canonical variable conditions:
\[ \langle \phi(q) | \hat{P}(q) |\phi(q)\rangle = \langle \phi(q) | i \frac{\partial}{\partial q} |\phi(q)\rangle = 0, \]  
(24)
\[ \langle \phi(q) | \hat{Q}(q) |\phi(q)\rangle = 0, \]  
(25)
\[ \langle \phi(q) | \hat{\Theta}(q) |\phi(q)\rangle = 0, \]  
(26)
\[ \langle \phi(q) | \hat{N} |\phi(q)\rangle = N_0. \]  
(27)

Eqs.(24) and (26) are automatically fulfilled by the definition, Eq.(14), of the operators \( \hat{Q}(q), \hat{\Theta}(q) \). Eq.(24) can be satisfied if the \( q \)-dependent phase of \( |\phi(q)\rangle \) is properly chosen. Eq.(27) is nothing but the constraint on \( |\phi(q)\rangle \) for the conservation of average particle number.

The first order canonical variable conditions:
\[ \langle \phi(q) | \frac{\partial \hat{Q}(q)}{\partial q} |\phi(q)\rangle = -1, \]  
(28)
\[ \langle \phi(q) | [\hat{Q}(q), \hat{\Theta}(q)] |\phi(q)\rangle = 0, \]  
(29)
\[ \langle \phi(q) | [\hat{Q}(q), \hat{N}] |\phi(q)\rangle = 0. \]  
(30)

One finds
\[ \langle \phi(q) | [\hat{Q}(q), \hat{P}(q)] |\phi(q)\rangle = i, \]  
(31)

which can be derived by differentiating Eq.(24) with respect to \( q \) and using Eq.(28). One can also derive from Eq.(27)
\[ \langle \phi(q) | [\hat{P}(q), \hat{N}] |\phi(q)\rangle = 0. \]  
(32)

These equations give constraints on the infinitesimal generators \( \hat{Q}(q), \hat{P}(q) \) concerning the normalization, Eq.(21), and the orthogonal condition to the particle number operator, Eq.(24).

Next we expand the equation of collective subspace, Eq.(10), to obtain a complete set of the basic equations for the adiabatic approximation. After rewriting Eq.(10) as
\[ \delta \langle \phi(q) | e^{-i\hat{G}} \hat{H} e^{i\hat{G}} - \frac{\partial \hat{H}}{\partial p} \hat{P}' - \frac{\partial \hat{H}}{\partial q} \hat{Q}' - \frac{\partial \hat{H}}{\partial N} \hat{N}' |\phi(q)\rangle = 0, \]  
(33)
one can expand each term with respect to \( p \) and \( n \) with use of the equations listed above.

The zeroth order equation of collective subspace:

\[
\delta \langle \phi(q) \rangle \hat{H} - \lambda(q)\hat{N} - \frac{\partial V}{\partial q} \hat{Q}(q) |\phi(q)\rangle = 0. \tag{34}
\]

The first order equation of collective subspace:

\[
\delta \langle \phi(q) \rangle [\hat{H} - \lambda(q)\hat{N}, \hat{Q}(q)] - \frac{1}{k}B(q)\hat{P}(q) |\phi(q)\rangle = 0. \tag{35}
\]

These equations are similar to the equations of path in the Villars’ ATDHF theory except that the present paper deals with the superconducting Hartree-Fock-Bogoliubov (HFB) state, and that the Hamiltonian accompanies the \( q \)-dependent chemical potential term \(-\lambda(q)\hat{N}\). As we mentioned in Sect. IV, the ATDHF theory has the problem that the solution satisfying these two equations is not uniquely determined. Although an additional validity condition was introduced to further constrain the solution in Ref. [3,4], the procedure of Ref. [3] does not fully solve the problem since the method does not work around the HF minima.

The non-uniqueness problem has been investigated in recent developments of the adiabatic theories, and in our opinion they are classified into two different approaches. The first one represented by Ref. [6] claims that the solution is uniquely determined if an RPA boundary condition is specified at the HF minimum and if the \( \lambda \)ian accompanies the

The second order equation of collective subspace:

\[
\delta \langle \phi(q) \rangle \frac{1}{2} [\hat{H} - \lambda(q)\hat{N}, \hat{Q}(q)], \hat{Q}(q)] - B(q)\Delta \hat{Q}(q) |\phi(q)\rangle = 0, \tag{36}
\]

where

\[
\Delta \hat{Q}(q) = \frac{\partial \hat{Q}}{\partial q} + \Gamma(q)\hat{Q}(q), \tag{37}
\]

\[
\Gamma(q) = -\frac{1}{2B(q)} \frac{\partial B}{\partial q}. \tag{38}
\]

This equation is equivalent in its mathematical form to the one given by Ref. [6] if the chemical potential term \(-\lambda(q)\hat{N}\) is neglected. The last term \(-B(q)\Delta \hat{Q}(q)\), often called a curvature term, was simply neglected in the original version of local harmonic approximation. In the next subsection, instead of neglecting this curvature term, we shall rewrite \(\Delta \hat{Q}(q)\) and change Eq.(36) into a workable form.

It is worth noting here the invariance of the adiabatic equations against the coordinate transformation. The collective momentum \( p \) undergoes the linear homogeneous transformation under the point transformation, Eq.(34). Therefore, different orders of the expansion with respect to the power of \( p \) are not mixed up under the point transformation. The invariance property of the basic equations of SCCM is thus inherited to each equation of the adiabatic approximation listed above. One can also confirm this property by seeing that the quantities appearing in the equations transform as

\[
\hat{Q}(q) \rightarrow \hat{Q}'(q') = \hat{Q}(q''), \quad \left( \frac{\partial q'}{\partial q} \right), \tag{39a}
\]

\[
\hat{P}(q) \rightarrow \hat{P}'(q') = \hat{P}(q'') \left( \frac{\partial q'}{\partial q} \right)^{-1}, \tag{39b}
\]

\[
\frac{\partial V}{\partial q} \rightarrow \frac{\partial V'}{\partial q'} = \frac{\partial V}{\partial q} \left( \frac{\partial q'}{\partial q} \right)^{-1}, \tag{39c}
\]
\[ B \rightarrow B'(q') = B(q(q')) \left( \frac{\partial q}{\partial q} \right)^2, \]  
\[ \Delta \dot{Q}(q) \rightarrow \Delta \dot{Q}'(q') = \Delta \dot{Q}(q). \]

III. LOCAL HARMONIC APPROXIMATION TO COLLECTIVE SUBSPACE

A. Local Harmonic Equations

In this section we give an approximate but concrete procedure to construct a solution of the adiabatic SCC method. To this end, we first derive, from the adiabatic equations, another set of equations of collective subspace which can be solved in a way similar to the RPA equation.

We first take a derivative of the zeroth order equation, Eq. (34), with respect to \( q \), which leads to

\[ \delta \langle \phi(q) \rangle [\dot{H} - \lambda(q)\dot{\hat{N}}] - C(q) \dot{Q}(q) - \frac{1}{2B(q)}[\dot{H} - \lambda(q)\dot{\hat{N}}, \frac{\partial V}{\partial q} \dot{Q}(q)] - \frac{\partial \lambda}{\partial q} \dot{\hat{N}} \langle \phi(q) \rangle = 0, \]

where \( \Delta \dot{Q}(q) \) and \( \Gamma(q) \) are given by Eqs. (37) and (38), respectively. Using Eqs. (36), we eliminate \( \Delta \dot{Q}(q) \) and rewrite Eq. (39) as

\[ \delta \langle \phi(q) \rangle [\dot{H} - \lambda(q)\dot{\hat{N}}] - C(q) \dot{Q}(q) - \frac{1}{2B(q)}[\dot{H} - \lambda(q)\dot{\hat{N}}, \frac{\partial V}{\partial q} \dot{Q}(q)] - \frac{\partial \lambda}{\partial q} \dot{\hat{N}} \langle \phi(q) \rangle = 0. \]

Furthermore, due to Eq. (42), we find

\[ \frac{\partial V}{\partial q} \dot{Q} = (\dot{H} - \lambda \dot{\hat{N}}) A, \]

where \( (\dot{H} - \lambda \dot{\hat{N}}) \) means \( a^\dagger a^\dagger \) and \( aa \) part of the operator \( \dot{H} - \lambda \dot{\hat{N}} \) containing two-quasiparticle creation and annihilation in the normal-ordered expression.

We thus replace Eqs. (34)–(36) by the equivalent set,

\[ \delta \langle \phi(q) \rangle [\dot{H}_M(q)] \langle \phi(q) \rangle = 0, \]

\[ \delta \langle \phi(q) \rangle [\dot{H}_M(q), \dot{Q}(q)] - \frac{1}{i} B(q) \dot{P}(q) \langle \phi(q) \rangle = 0, \]

\[ \delta \langle \phi(q) \rangle [\dot{H}_M(q), \dot{P}(q)] - C(q) \dot{Q}(q) - \frac{1}{2B(q)}[\dot{H}_M(q), (\dot{H} - \lambda(q)\dot{\hat{N}})_A, \dot{Q}(q)] - \frac{\partial \lambda}{\partial q} \dot{\hat{N}} \langle \phi(q) \rangle = 0. \]

In Eq. (43) and (46), \( \dot{H} - \lambda \dot{\hat{N}} \) has been replaced by

\[ \dot{H}_M(q) = \dot{H} - \lambda(q)\dot{\hat{N}} - \frac{\partial V}{\partial q} \dot{Q}(q), \]

since the last term has no influence. The operator \( \dot{H}_M(q) \) may be regarded as the Hamiltonian in the moving frame. The second and third terms can be identified with generalized cranking terms associated with the pairing rotation and the LACM, respectively.

Equations (43) and (46) are linear equations with respect to the one-body operators \( \dot{Q}(q) \) and \( \dot{P}(q) \). They have essentially the same structure as the standard RPA equations except for the last two terms in Eq. (46).

The quantity \( C(q) \) is the local stiffness parameter defined as the second (covariant) derivative of the collective potential \( V(q) \). The infinitesimal generators \( Q(q) \) and \( P(q) \) are thus closely related to the harmonic normal...
modes locally defined for $|\phi(q)\rangle$ and the moving frame Hamiltonian $\hat{H}_M(q)$. These equations may be called local harmonic equations.

It was shown in Ref. [7] that the zeroth, first and second order equations of ATDHF give a valley line of a potential energy surface in a multi-dimensional configuration space associated with the TDHF states. Similarly, the local harmonic equations we have obtained, Eqs.(44)-(46), define the valley of the multi-dimensional potential energy surface. The solution of these equations will be uniquely determined if a suitable boundary condition is specified. These features are similar to the formulation of Ref. [8] where the valley equation of the potential energy surface is derived from the decoupling condition.

We remark again that the local harmonic equations in the present paper differ from the ones of Rowe-Bassermann [12] and Marumori [13] with respect to the third and the fourth terms of Eq.(46), which arise from the curvature term (derivative of the generator) and the particle number constraint, respectively. It is important to keep the curvature term in order to maintain the relation between the collective subspace and the valley of the potential surface. We also note that the present formalism is invariant with respect to the point transformation of the collective coordinate, as is the formulation of Ref. [8].

**B. Matrix Formulation of Local Harmonic Equations**

Let us now give a procedure to find the operators $\hat{Q}(q), \hat{P}(q)$ that satisfy the local harmonic equations, (45) and (46), for a given state $|\phi(q)\rangle$. Since they are linear equations with respect to these operators, it can be solved in an analogous way to the standard RPA. To show this, we first express the operator $\hat{P}(q)$ and $\hat{N}$ in terms of the quasiparticle operators:

$$\hat{P}(q) = i \sum_{\alpha > \beta} \left( P_{\alpha\beta}(q) a_\alpha^\dagger a_\beta^\dagger - P_{\alpha\beta}^*(q) a_\beta a_\alpha \right) = \hat{P}(q)^\dagger,$$

$$\hat{N} = \sum_{\alpha > \beta} \left( N_{\alpha\beta}(q) a_\alpha^\dagger a_\beta^\dagger + N_{\alpha\beta}^*(q) a_\beta a_\alpha \right).$$

Note that the $a^\dagger a$ and c-number parts are neglected here since they do not change the state vector $|\phi(q)\rangle$ except for the phase. The Hamiltonian $\hat{H}$ is also expressed in terms of the same quasiparticle operators. Assuming that the matrix elements $Q_{\alpha\beta}, P_{\alpha\beta}$ are real, the local harmonic equations are written as the following matrix equations.

\[
\begin{align*}
(A - B)Q - B(q)P &= 0, \\
(A + B)P - C(q)Q - \frac{1}{B(q)}DQ - \lambda' N &= 0, \\
P^T N &= 0, \\
2Q^T P &= 1, \\
\lambda' &= \frac{\partial \lambda}{\partial q}.
\end{align*}
\]

Here all quantities are functions of $q$, and $Q = (..., Q_{\alpha\beta}, ...)^T$, $P = (..., P_{\alpha\beta}, ...)^T$, and $N = (..., N_{\alpha\beta}, ...)^T$, are the vector representation of the matrix elements with $\alpha > \beta$. $A$ and $B$ are the matrices whose elements are given by

\[
\begin{align*}
(A)_{\alpha\beta, \gamma\delta} &= \delta_{\alpha\gamma} \delta_{\beta\delta} (e_\alpha + e_\beta) + v_{22}^{\alpha\beta, \gamma\delta}, \\
(B)_{\alpha\beta, \gamma\delta} &= v_4^{00}_{\alpha\beta, \gamma\delta}.
\end{align*}
\]

in terms of the matrix elements of the moving frame Hamiltonian

\[
\begin{align*}
\hat{H}_M(q) &= \sum_\alpha e_\alpha a_\alpha^\dagger a_\alpha \\
+ &\frac{1}{4} \sum_{\alpha, \beta, \gamma, \delta} v_{22}^{\alpha\beta, \gamma\delta} a_\alpha^\dagger a_\beta^\dagger a_\gamma a_\delta.
\end{align*}
\]
Here, due to Eq. (51), \( a^\dagger a^\dagger \) and \( aa \) parts of \( \hat{H}_M(q) \) vanish, and \( a^\dagger a \) part of \( \hat{H}_M(q) \) is diagonalized. The matrix elements of the residual interactions in Eqs. (52b)-(52d) are antisymetrized with respect to the quasiparticle indices. The matrices \( A \) and \( B \) have the same structures as the ones often defined in the quasiparticle RPA formalism [7]. The matrix \( D \) is defined by

\[
(D)_{\alpha\beta,\gamma\delta} = \frac{1}{2} \langle \phi(q) \left| [[\hat{H}_M(q), (\hat{H} - \lambda(q)\hat{N})], a_\alpha^\dagger a_\beta^\dagger + a_\beta a_\alpha], a_\gamma a_\delta \right| \phi(q) \rangle. \tag{53}
\]

These matrix elements are expressed also in terms of the Hamiltonian matrix elements as

\[
\begin{align*}
(D)_{\alpha\beta,\gamma\delta} &= \left( d^{22}_{\alpha\beta,\gamma\delta} - d^{40}_{\alpha\beta,\gamma\delta} + d^{11}_{\alpha\gamma,\delta\gamma} - d^{11}_{\beta\gamma,\alpha\delta} + d^{11}_{\delta\gamma,\alpha\beta} - d^{11}_{\gamma\delta,\alpha\beta} \right)/2, \\
&= \frac{1}{2} \sum_\epsilon (v^{31}_{\alpha\beta\gamma\epsilon,\delta} h^{\delta\epsilon} - v^{31}_{\alpha\beta\delta,\gamma\epsilon} h^{\gamma\epsilon} - v^{13}_{\alpha\gamma\delta,\beta\epsilon} h^{\beta\epsilon} + v^{13}_{\beta\gamma\delta,\alpha\epsilon} h^{\alpha\epsilon} ). \\
&= \frac{1}{2} \sum_\gamma\delta (v^{31}_{\alpha\beta\gamma\delta,\epsilon} h^{\gamma\delta} - v^{31}_{\alpha\beta\delta,\gamma\epsilon} h^{\gamma\epsilon} + v^{31}_{\beta\gamma\delta,\alpha\epsilon} h^{\alpha\epsilon} - v^{31}_{\gamma\delta,\beta\epsilon} h^{\beta\epsilon} + v^{13}_{\alpha\beta\gamma,\delta\epsilon} h^{\delta\epsilon} - v^{13}_{\alpha\beta\delta,\gamma\epsilon} h^{\gamma\epsilon} + v^{13}_{\beta\gamma\delta,\alpha\epsilon} h^{\alpha\epsilon} - v^{13}_{\gamma\delta,\beta\epsilon} h^{\beta\epsilon} ).
\end{align*}
\]

where \( h_{\alpha\beta} \) is the matrix elements of \((\hat{H} - \lambda\hat{N})_A \) defined by

\[
(\hat{H} - \lambda\hat{N})_A = \sum_{\alpha,\beta} h_{\alpha\beta} (a_\alpha^\dagger a_\beta^\dagger + a_\beta a_\alpha). \tag{55}
\]

Note that \( D \) contains the matrix elements of the type \( v^{13} \) and \( v^{31} \). These terms of the Hamiltonian do not contribute to the standard RPA equations.

The solution of the matrix equations is obtained as follows. From Eq. (52), one obtains

\[
\begin{align*}
Q &= \lambda' B(q) \left( (A + B)(A - B) - D - \Omega \right)^{-1} N, \\
P &= \lambda' (A - B) \left( (A + B)(A - B) - D - \Omega \right)^{-1} N, \tag{56a}
\end{align*}
\]

with

\[
\Omega = B(q)C(q). \tag{57}
\]

The condition that the collective mode is orthogonal to the number operator, Eq. (50c), gives the following equation

\[
S(\Omega) \equiv N^T (A - B) \left( (A + B)(A - B) - D - \Omega \right)^{-1} N = 0. \tag{58}
\]

The quantity \( \Omega = B(q)C(q) \) represents the square of the frequency \( \omega = \sqrt{BC} \) of the local harmonic mode, which is not necessarily positive. This equation can be regarded as a dispersion equation to determine \( \Omega = \omega^2 \) as a zero point of \( S(\Omega) \). The normalization condition, Eq. (50a), then gives a constraint on the value of \( \lambda' B(q) \). The value of the mass parameter \( B(q) \) is arbitrary, being related to the invariance under the point transformation Eq. (1). A choice of the coordinate, \( q \), specifies a value of the mass parameter, \( B(q) \).

In practice, the coordinate is often scaled so as to make the mass parameter unity.

When the residual interactions are the separable forces such as the monopole pairing and the quadruple-quadrupole forces, the local harmonic equations reduce to a simpler form. The dispersion equation for the separable interaction does not require a matrix inversion as in Eq. (58). The details are discussed in Appendix.

Ref. [1] has discussed a problem of spurious (Nambu-Goldstone) modes for local harmonic approaches, and stated that the RPA equation at non-equilibrium points must be extended in order to guarantee separation of the spurious modes. However, no practical way of solving the equation was given because the equation has parameters which we do not have a method to calculate. In our present formulation, the RPA equation is indeed extended to assure the number conservation.
C. Construction of Collective Subspace

Let us finally give algorithms to construct the collective subspace $|\phi(q)\rangle$ as a function of the collective coordinate $q$. Note that the local harmonic equations, Eqs. (44)- (46), are regarded as local equations in a sense that the equations can be solved independently for different values of $q$. At the HFB ground state, $|\phi_0\rangle$, defined by the HFB equation

$$\delta \langle \phi_0 | \hat{H} - \lambda_0 \hat{N} | \phi_0 \rangle = 0,$$

we find $\partial V/\partial q = 0$. Therefore, $|\phi_0\rangle$ is always a state on the collective subspace because Eq.(44) is automatically satisfied. Eqs. (45) and (46) reduce to the standard RPA equations at $|\phi_0\rangle$ since the last two terms in Eq.(46) vanishes. The operators $\hat{Q}, \hat{P}$ are then determined as one of the normal modes of the RPA equation.

For non-equilibrium states, in general, Eq.(44) and the other two equations, (45) and (46), are coupled. We may solve the coupled equations in an iterative way. As discussed in Sect. III B one can find the operators $\hat{Q}(q)^{(n)}, \hat{P}(q)^{(n)}$ by solving Eqs.(45) and (46) for a given trial state $|\phi(q)^{(n)}\rangle$ (n denoting the iteration step). This defines the moving frame Hamiltonian $\hat{H}_{mf}(q)^{(n+1)} = \hat{H} - \lambda(q)^{(n+1)} \hat{N} - \left(\frac{\partial V}{\partial q}\right)^{(n)} \hat{Q}(q)^{(n)}$, which can be used to construct a trial state $|\phi(q)^{(n+1)}\rangle$ for the next iteration. If the iteration converges, one obtains a state $|\phi(q)\rangle$ on which Eqs. (44)-(46) are simultaneously satisfied. Repeating the same procedure for different values of $q$, one finally obtains the collective subspace $|\phi(q)\rangle$ and the collective Hamiltonian as a function of $q$.

We remark here that the operator $\hat{P}(q)$ thus determined does not guarantee Eq.(21), although the other equations are satisfied. In this sense, the local harmonic solution is an approximate solution. The exact solution satisfying all the basic equations in Sect.II B may not exist in realistic situations. Only when the system is “exactly decoupled” \cite{8}, the above procedure gives the exact solution.

It is possible to choose another algorithm which satisfies Eq.(21) at the sacrifice of errors in Eq. (44). Let $|\phi(q_0)\rangle$ be a solution that satisfies the basic equations at $q = q_0$. The infinitesimal generators $\hat{Q}(q_0), \hat{P}(q_0)$ are determined by solving Eqs.(45) and (46). Then one can generate the state $|\phi(q_0 + \delta q)\rangle$ for an infinitesimal shift of the collective coordinate as

$$|\phi(q_0 + \delta q)\rangle = e^{-i\delta q \hat{P}(q_0)} |\phi(q_0)\rangle.$$  

Repeating this procedure, one can construct a collective subspace. This solution should coincide with the one solved by the previous method if the system is exactly decoupled. Difference between the two gives a quality of decoupling for the collective subspace in the adiabatic approximation. The second procedure can be used to provide an initial guess, $|\phi(q)\rangle^{(0)}$, for the iteration of the first method.

IV. EXTENSION TO MULTI-DIMENSIONAL COLLECTIVE SUBSPACE

In this section we extend the adiabatic SCC method to a case of multi-dimensional collective subspace described by $D$ collective coordinates and conjugate momenta $\{q^i, p_i; i = 1, ..., D\}$.

One can easily derive the basic equations of the adiabatic SCC method in parallel to the derivation given in Sections II by noting first that Eqs. (12-14) are now extended to

$$|\phi(q, p, N)\rangle = e^{i\hat{G}(q,p,n)} |\phi(q)\rangle,$$

$$\hat{G} = p_i \hat{Q}^i(q) + n \hat{\Theta}(q),$$

where the operator $\hat{Q}^i(q)$ have now $D$ components having coordinate label $i$. It is implied here and hereafter that the same coordinate index ($i$ in the above expression) appearing in the super- and subscripts means to take the summation over it. The infinitesimal generator $\hat{P}(q)$ have also $D$ components each of which is related to the derivative $i \frac{\partial}{\partial q_i} |\phi(q)\rangle$. In the following, the coordinate dependence is often omitted. For instance, $B^{ij}(q)$ and $\hat{Q}^i(q)$ will be simply denoted by $B^{ij}$ and $\hat{Q}^i$, respectively.

The adiabatic collective Hamiltonian is expressed as

$$\mathcal{H}(q, p, N) = V(q) + \frac{1}{2} B^{ij}(q)p_ip_j + \lambda(q)n.$$  

(63)
The zeroth and the first order equations of the collective subspace are derived as
\[
\delta \langle \phi(q) | \dot{N} - \lambda(q) \dot{\hat{N}}, \dot{Q}^i | \phi(q) \rangle = 0,
\]
\[
\delta \langle \phi(q) | [\dot{\hat{N}} - \lambda(q) \hat{N}, \dot{\hat{Q}}] - \frac{1}{\ell} B^{ij} \dot{P}_j | \phi(q) \rangle = 0,
\]
while the second order equation becomes
\[
\delta \langle \phi(q) | \left[ \frac{1}{2} \dot{\hat{N}} - \lambda(q) \hat{N}, \dot{\hat{Q}}^i, \dot{\hat{Q}}^j \right] + \frac{1}{6} \frac{\partial V}{\partial q^k} \dot{\hat{Q}}^k, \dot{\hat{Q}}^i, \dot{\hat{Q}}^j \right] - \frac{1}{2} \left( B^{ik} \dot{\hat{Q}}^j_{ik} + B^{jk} \dot{\hat{Q}}^i_{jk} \right) \rangle | \phi(q) \rangle = 0
\]
with
\[
\dot{\hat{Q}}^i_{ij} = \frac{\partial \dot{\hat{Q}}^i}{\partial q^j} + \Gamma^i_{kj} \dot{\hat{Q}}^k,
\]
\[
\Gamma^i_{kj} = \frac{1}{2} B^{il} \left( \frac{\partial B_{kj}}{\partial q^l} + \frac{\partial B_{kl}}{\partial q^j} - \frac{\partial B_{lj}}{\partial q^k} \right),
\]
where $B_{ij}$ is the inverse matrix of $B^{ij}$ and the bracket including three operators defined by
\[
[A, B, C] = \frac{1}{2} ([A, B], C] + [[A, C], B]).
\]
Expanding the canonical variable condition with respect to $p_i$ and $n$, the following equations are derived;
\[
\langle \phi(q) | \dot{P}_i | \phi(q) \rangle = 0,
\]
\[
\langle \phi(q) | \dot{N} | \phi(q) \rangle = N_0,
\]
and
\[
\langle \phi(q) | [\dot{\hat{Q}}^i, \dot{P}_j] | \phi(q) \rangle = i \delta_{ij},
\]
\[
\langle \phi(q) | [\dot{\hat{Q}}^i, \dot{\hat{N}}] | \phi(q) \rangle = 0,
\]
\[
\langle \phi(q) | [\dot{P}_i, \dot{\hat{N}}] | \phi(q) \rangle = 0.
\]
These basic equations are invariant under the point transformation of the collective variables
\[
q^i \rightarrow q'^{i}(q),
\]
\[
p_i \rightarrow p'_i = p_j \times (\partial q^j / \partial q'^i).
\]
We have adopted the vector-tensor notation \textsuperscript{20} to manifest the transformation properties under the point transformation. Quantities which have a coordinate index in the subscript and have the superscript have the transformation properties of the covariant and contravariant vectors, respectively. For example,
\[
\dot{Q}^i \rightarrow \dot{Q}'^i = \dot{Q}^i \times (\partial q^j / \partial q'^i),
\]
\[
\dot{P}_i \rightarrow \dot{P}'_i = \dot{P}_j \times (\partial q^j / \partial q'^i).
\]
The mass tensor $B^{ij}$ is the contravariant tensor of second rank. The operator $Q^{ij}$ defined by Eq.(67) is the covariant derivative of $Q^i$, and $\Gamma^i_{kj}$ is the Christoffel symbol where the mass tensor $B_{ij}$ plays the role of metric tensor.

Let us now derive local harmonic equations of collective subspace. Taking the $q$-derivative, the zeroth order equation \textsuperscript{(54)} leads to
\[
\delta \langle \phi(q) | [\dot{\hat{N}} - \lambda(q) \hat{N}, \dot{\hat{Q}}^i] - C_{ij}(q) \dot{\hat{Q}}^j - \frac{\partial V}{\partial q^i} \dot{\hat{Q}}^i - \frac{\partial \lambda}{\partial q^i} \dot{\hat{N}} | \phi(q) \rangle = 0,
\]
\[
C_{ij}(q) = \frac{\partial^2 V}{\partial q^i \partial q^j} - \Gamma^k_{ij} \frac{\partial V}{\partial q^k}.
\]
As we have done for the $D = 1$ case, we would like to eliminate the covariant derivative $\hat{Q}^i_\nu$ in Eq. (78) in order to give a feasible form of the local harmonic equation. This was done for the $D = 1$ case with help of the second order equation of the collective subspace. The corresponding equations (33) give $D(D + 1)/2$ constraints, while number of unknown parameters, $\hat{Q}^i_\nu$, is $D^2$. In fact, Eq. (66) is equivalent to

$$\delta \langle \phi(q) | \frac{1}{2} [\hat{H} - \lambda(q)\hat{N}, \hat{Q}^i_\nu] + \frac{1}{6} [[\hat{V}/\partial q^k, \hat{Q}^i_\nu], \hat{Q}^i_\nu] - (B^i_k\hat{Q}^k_\nu + \check{R}^i_\nu) | \phi(q) \rangle = 0,$$

where $\check{R}^i_\nu$ are arbitrary one-body operators which are antisymmetric for exchange of indices $i$ and $j$. If we choose $\check{R}^i_\nu = 0$, we can eliminate the derivative term $\partial_q \hat{Q}^i_\nu$. Then, Eq. (78) leads to

$$\delta \langle \phi(q) | [\hat{H} - \lambda(q)\hat{N}, \hat{Q}^i_\nu] - C_{ij}\hat{Q}^j_\nu - \frac{1}{2}[[\hat{H} - \lambda(q)\hat{N}, (\hat{H} - \lambda(q)\hat{N})]_A, B_{ij}\hat{Q}^j_\nu] - \partial_q \hat{N} | \phi(q) \rangle = 0.$$

This equation is an analog of Eq. (66) and is linear with respect to the infinitesimal generators $\hat{Q}^i, \hat{P}_i$. We can numerically solve Eqs. (64), (65) and (81) on the same line as in Sect. III B and III C.

It should be remarked that the local harmonic equation Eq. (81) for $D > 1$ are derived from equations, (64) and (66), but with an additional condition $\check{R}^i_\nu = 0$ in Eq. (66). This condition is introduced to obtain the local harmonic equations parallel to the one-dimensional case.

V. CONCLUSIONS

We have formulated the adiabatic approximation to the general framework of the selfconsistent collective coordinate method in order to describe large amplitude collective motions in superconducting nuclei. The formalism, based on the TDHFB equations of motion, guarantees the conservation of particle number in a transparent way. We have shown that the equations of collective subspace are reduced to local linear equations for the infinitesimal generators, which can be solved with use of quasiparticle representation of the Hamiltonian matrix elements. This provides a complete procedure to determine the states $\langle \phi(q) | [\hat{H} - \lambda(q)\hat{N}, \hat{Q}^i_\nu] - C_{ij}\hat{Q}^j_\nu - \frac{1}{2}[[\hat{H} - \lambda(q)\hat{N}, (\hat{H} - \lambda(q)\hat{N})]_A, B_{ij}\hat{Q}^j_\nu] - \partial_q \hat{N} | \phi(q) \rangle = 0.$

We emphasize that the equations given in this paper are solvable by means of the matrix method similar to the standard RPA. We hope that the present adiabatic theory is useful to solve number of open questions in the realistic studies of nuclear large amplitude collective motion.

APPENDIX: SOLUTION FOR THE SEPARABLE INTERACTIONS

In this appendix, we give solutions of the local harmonic equations of collective subspace for the case where the two-body interaction is given by the separable forces. We assume that the Hamiltonian is given by

$$\hat{H} = \hat{h}_0 - \frac{\kappa}{2} \hat{F}^\dagger \hat{F},$$

(A1)

where $\hat{h}_0(= \hat{h}_0^\dagger)$ and $\hat{F}$ are one-body operators. Equivalently, one may write

$$\hat{H} = \hat{h}_0 - \frac{\kappa}{2} \hat{F}^{(+)} \hat{F}^{(+)} + \frac{\kappa}{2} \hat{F}^{(-)} \hat{F}^{(-)},$$

(A2)

$$\hat{F}^{(\pm)} \equiv (\hat{F} \pm \hat{F}^\dagger)/2 = \pm \tilde{F}^{(\pm)}\dagger.$$

(A3)

For the separable forces, it is customary to neglect the Fock term of the forces. This approximation is easily and consistently implemented in the SCCM by assuming that the equation of motion for the time-dependent mean-field state $|\phi(t)\rangle$ is now given by the time-dependent Hartree-Bogoliubov equation without the Fock terms,

$$\delta \langle \phi(t) | i \frac{\partial}{\partial t} - \hat{h}(t) | \phi(t) \rangle = 0,$$

(A4)

$$\hat{h}(t) = \hat{h}_0 - \kappa \hat{F}^{(+)} \langle \phi(t) | \hat{F}^{(+)} | \phi(t) \rangle + \kappa \hat{F}^{(-)} \langle \phi(t) | \hat{F}^{(-)} | \phi(t) \rangle.$$

(A5)
The local harmonic equations (44)-(46) then become
\[
\delta \langle \phi(q) | \hat{h}_M(q) | \phi(q) \rangle = 0, \tag{A6}
\]
\[
\delta \langle \phi(q) | [\hat{h}_M(q), \hat{Q}(q)] - f_Q^{(-)} \hat{F}^{(-)} - \frac{1}{i} B(q) \hat{P}(q) | \phi(q) \rangle = 0, \tag{A7}
\]
\[
\delta \langle \phi(q) | [\hat{h}_M(q), \frac{1}{i} B(q) \hat{P}(q)] - f_P^{(+)} \hat{F}^{(+)} - B(q) C(q) \hat{Q}(q) - f_R^{(+)} \hat{F}^{(+)}.
\]
\[
-[\hat{F}^{(-)}, (\hat{h}(q) - \lambda(q) \hat{N}) A] f_Q^{(-)} - f_N \hat{N} | \phi(q) \rangle = 0, \tag{A8}
\]
where \( \hat{h}_M(q) \) is the mean-field Hamiltonian in the moving frame defined by
\[
\hat{h}_M(q) = \hat{h}(q) - \frac{\partial V}{\partial q} \hat{Q}(q) - \lambda(q) \hat{N}, \tag{A9}
\]
\[
\hat{h}(q) = \hat{h}_0 - \kappa \hat{F}^{(+)} \langle \phi(q) | \hat{F}^{(+)} | \phi(q) \rangle, \tag{A10}
\]
and definitions of other symbols are
\[
\begin{align*}
f_Q^{(-)} &= -\kappa \langle \phi(q) | [\hat{F}^{(-)}, \hat{Q}(q)] | \phi(q) \rangle, \tag{A11a} \\
f_P^{(+)t} &= \kappa \langle \phi(q) | [\hat{F}^{(+)}, \frac{1}{i} B(q) \hat{P}(q)] | \phi(q) \rangle, \tag{A11b} \\
f_R^{(+)} &= -\kappa \langle \phi(q) | [[\hat{F}^{(+)}, (\hat{h}(q) - \lambda(q) \hat{N}) A], \hat{Q}(q)] | \phi(q) \rangle / 2, \tag{A11c} \\
f_N &= B(q) \frac{\partial \lambda}{\partial q}. \tag{A11d}
\end{align*}
\]

We express all operators in the above equations in terms of the quasiparticle operators \( \{ a_\alpha^t, a_\alpha \} \) defined for \( \hat{h}_M(q) \) and \( | \phi(q) \rangle \). For example,
\[
\begin{align*}
\hat{h}_M(q) &= \sum_\alpha e_\alpha a_\alpha^t a_\alpha, \tag{A12} \\
\hat{F}^{(+)} &= \sum_{\alpha > \beta} F^{(+)}_{\alpha \beta} a_\alpha^t a_\beta + a_\beta a_\alpha + \sum_{\alpha > \beta} F^{(+)}_{\alpha \beta} a_\alpha^t a_\beta, \tag{A13} \\
\hat{F}^{(-)} &= \sum_{\alpha < \beta} F^{(-)}_{\alpha \beta} a_\alpha a_\beta - a_\beta a_\alpha + \sum_{\alpha < \beta} F^{(-)}_{\alpha \beta} a_\alpha a_\beta. \tag{A14}
\end{align*}
\]

We have assumed that all matrix elements are real. Equations (A3-A8) are then reduced to linear equations for the matrix elements \( Q_{\alpha \beta}, P_{\alpha \beta} \) of the infinitesimal generators \( \hat{Q}(q), \hat{P}(q) \). They are easily solved to give the expression
\[
\begin{align*}
Q_{\alpha \beta} &= \frac{e_\alpha + e_\beta}{(e_\alpha + e_\beta)^2 - \Omega} F^{(-)}_{\alpha \beta} f_Q^{(-)} + \frac{1}{(e_\alpha + e_\beta)^2 - \Omega} \left( F^{(+)}_{\alpha \beta} f_P^{(+)} + R^{(-)}_{\alpha \beta} f_Q^{(-)} + N_{\alpha \beta} f_N \right), \tag{A15} \\
BP_{\alpha \beta} &= \frac{e_\alpha + e_\beta}{(e_\alpha + e_\beta)^2 - \Omega} \left( F^{(+)}_{\alpha \beta} f_P^{(+)} + P^{(-)}_{\alpha \beta} f_Q^{(-)} + N_{\alpha \beta} f_N \right) + \frac{\Omega}{(e_\alpha + e_\beta)^2 - \Omega} F^{(-)}_{\alpha \beta} f_Q^{(-)}, \tag{A16} \\
f_P^{(+)} &= f_P^{(+)} + f_R^{(+)}, \tag{A17}
\end{align*}
\]
where we introduced the one-body operator
\[
\hat{R}(q)^{\pm} \equiv [\hat{F}^{\pm}_B(q), (\hat{h}(q) - \lambda(q) \hat{N}) A] = \sum_{\alpha > \beta} R^{(\pm)}_{\alpha \beta} (a_\alpha^t a_\beta + a_\beta a_\alpha), \tag{A18}
\]
with \( \hat{F}^{\pm}_B(q) \) being the last terms of \( \hat{F}^{\pm} \) in Eqs.(A13-A14).
Inserting this expression for the definition of \( f_{PR}^{(+)} \), \( f_{Q}^{(-)} \), we obtain the equations for unknown quantities \( f_{PR}^{(+)} \), \( f_{Q}^{(-)} \), \( f_{N} \). Similarly, the condition of orthogonality to the number operator Eq.(50c) gives another equation for \( f_{PR}^{(+)} \), \( f_{Q}^{(-)} \), \( f_{N} \). They are summarized as a linear homogeneous equation which can be written in a 3 \times 3 matrix form

\[
\begin{pmatrix}
S_{xx'}(\Omega) \\
\frac{f_{PR}^{(+)}}{f_{Q}^{(-)}} \\
\frac{f_{N}}{f_{N}}
\end{pmatrix}
= 0,
\]

where

\[
S_{11} = 2S_{F(+)F(+)}^{(1)} + S_{R(+)F(+)}^{(2)} - \frac{1}{\kappa},
\]

\[
S_{12} = 2\Omega S_{F(+)F(-)}^{(2)} + 2S_{F(+)R(-)}^{(1)} + S_{R(+)F(-)}^{(1)} + S_{R(+)R(-)}^{(2)},
\]

\[
S_{13} = 2S_{F(+)N}^{(1)} + S_{R(+)N}^{(2)},
\]

\[
S_{21} = 2S_{F(-)F(+)}^{(2)},
\]

\[
S_{22} = 2S_{F(-)F(-)}^{(1)} + 2S_{F(-)R(-)}^{(2)} - \frac{1}{\kappa},
\]

\[
S_{23} = 2S_{F(-)N}^{(2)},
\]

\[
S_{31} = S_{N F(+)}^{(1)},
\]

\[
S_{32} = \Omega S_{N F(-)}^{(2)} + S_{N R(-)},
\]

\[
S_{33} = S_{N N}^{(1)}.
\]

The functions \( S_{XY}^{(1)} \) with the symbols \( X, Y \) denoting \((X, Y) = (F(+)F(+)F(+), (F(+)R(-)), (F(+)N), (R(+)F(-)), (F(-)F(-)), (N, N), (N, F(+)F(+)), (N, R(-))\) are given by

\[
S_{XY}^{(1)} = \sum_{\alpha > \beta} \frac{\epsilon_{\alpha} + \epsilon_{\beta}}{\epsilon_{\alpha} + \epsilon_{\beta}} - \Omega X_{\alpha \beta} Y_{\alpha \beta},
\]

while the functions \( S_{XY}^{(2)} \) with \((X, Y) = (F(+)F(-)), (R(+)F(+)F(+)), (R(+)R(-)), (R(+)N), (F(-)F(+)F(-)), (F(-)R(-)), (F(-)N), (N, F(-))\) are given by

\[
S_{XY}^{(2)} = \sum_{\alpha > \beta} \frac{1}{\epsilon_{\alpha} + \epsilon_{\beta}} X_{\alpha \beta} Y_{\alpha \beta}.
\]

The value of \( \Omega \) is determined by finding the zero point of the dispersion equation

\[
\det[S_{xx'}(\Omega)] = 0.
\]

Normalizations of \( f_{PR}^{(+)} \), \( f_{Q}^{(-)} \), \( f_{N} \) are fixed by the condition Eq. (104). It is straightforward to extend the above procedure to the case where the two-body interaction is given by a sum of the separable forces.
