Abstract

The article presents the results of clinical studies of domestic cats and dogs with diabetes mellitus on the background of obesity at the beginning and for a month of treatment. Domestic cats with diabetes were prescribed active exercise and industrial diet Royal Canin Diabetic Feline, dogs – Royal Canin Diabetic DS37. The portion size was determined according to the manufacturer's recommendations. Treatment of small animals for obesity, both alimentary and endocrine, preferably involves feeding food in limited quantities to cause controlled weight loss, as well as increased physical activity, which can provide additional energy expenditure. Successful weight loss can reduce the effects of comorbidities associated with obesity, such as improved mobility in osteoarthritis, increased insulin sensitivity and the reversal of other metabolic disorders, and improved quality of life. The main pathogenetic therapy for animals with diabetes for both domestic cats and dogs is the mandatory use of insulin. Researching the market of drugs in Ukraine, we chose the most affordable and effective veterinary drug – Caninsulin. The dose of insulin was selected individually for each animal by plotting a curve of blood glucose concentration over three days. At the beginning of treatment and at the end of the course, we conducted a comprehensive study of animals of both species. In cats, the general condition significantly improved as a result of treatment: only one animal had anemia of the mucous membranes. Anxiety, bradycardia, hypothermia and vomiting and bradycardia were not reported. A decrease in the rate of shortness of breath and drowsiness also indicates an improvement in the condition of cats with obesity due to diabetes. The improvement of the general condition of domestic dogs was evidenced by the restoration of the condition of the coat (about 4 times), the restoration of appetite in 66.7 %. Only one dog had anemia of the mucous membranes. Mucous membranes; temperature within the physiological norm; vomiting and bradycardia were not reported. An itching disappeared completely. Within one month, there was a tendency to decrease the body weight of animals of both groups, but due to the insufficient duration of treatment, their fatness still remained excessive. Which indicates the need for further correction of the pathological condition.

Key words: symptoms, hypothyroidism, endocrine obesity, overweight, dogs.

The article presents the results of clinical studies of domestic cats and dogs with diabetes mellitus on the background of obesity at the beginning and for a month of treatment. Domestic cats with diabetes were prescribed active exercise and industrial diet Royal Canin Diabetic Feline, dogs – Royal Canin Diabetic DS37. The portion size was determined according to the manufacturer's recommendations. Treatment of small animals for obesity, both alimentary and endocrine, preferably involves feeding food in limited quantities to cause controlled weight loss, as well as increased physical activity, which can provide additional energy expenditure. Successful weight loss can reduce the effects of comorbidities associated with obesity, such as improved mobility in osteoarthritis, increased insulin sensitivity and the reversal of other metabolic disorders, and improved quality of life. The main pathogenetic therapy for animals with diabetes for both domestic cats and dogs is the mandatory use of insulin. Researching the market of drugs in Ukraine, we chose the most affordable and effective veterinary drug – Caninsulin. The dose of insulin was selected individually for each animal by plotting a curve of blood glucose concentration over three days. At the beginning of treatment and at the end of the course, we conducted a comprehensive study of animals of both species. In cats, the general condition significantly improved as a result of treatment: only one animal had anemia of the mucous membranes. Anxiety, bradycardia, hypothermia and itching disappeared completely. Within one month, there was a tendency to decrease the body weight of animals of both groups, but due to the insufficient duration of treatment, their fatness still remained excessive. Which indicates the need for further correction of the pathological condition.

Key words: symptoms, hypothyroidism, endocrine obesity, overweight, dogs.
The obesity diet is developed by a veterinarian after examination of the animal. If you follow a natural diet, it is recommended to feed: lean meat of several varieties, lean sea fish, uncooked cereals, dairy products, vegetable oils, vitamins. All products must be easily digestible and of good quality in terms of nutritional value. Animals should be fed in small portions three times a day (German et al., 2008; Bissot et al., 2009; Owens et al., 2014; German et al., 2015; Christmann et al., 2015; Flanagan et al., 2017).

In modern veterinary practice, there are no specific protocols for the treatment of small animals with diabetes, which allows you to make a treatment plan for each animal individually.

That is why the aim of the work is to determine the directions of correction of the pathological condition of domestic cats and dogs with diabetes mellitus on the background of obesity.

Material and methods

The research was conducted during 2018–2020 on the basis of veterinary clinics in Poltava and Kharkiv.

In this work we have investigated 12 domestic cat and dog 9, in which the comprehensive survey of diagnosed diabetes symptomatic obesity. For we have taken control of clinically healthy animals with no visible signs of any pathology – 20 domestic cats and 15 domestic dogs. Registered animals admitted to veterinary clinics were examined according to the general scheme: anamnesis was collected, habit, condition of skin, visible mucous membranes were determined, thermometry, weighing, morphometric measurements and calculations were performed, functional state of organs and systems was examined (McCann et al., 2007; Lokes-Krupka, 2019).

Correction of the pathological condition of animals in both experimental groups was aimed at correcting the diet, the introduction of additional exercise and insulin therapy. Additionally, if necessary, the animals were given symptomatic treatment. Clinical evaluation of the effectiveness of treatment of animals was performed 30 days after treatment.
Results and discussion

Domestic cats with diabetes were prescribed active exercise and industrial diet Royal Canin Diabetic Feline, dogs – Royal Canin Diabetic DS37. The portion size was determined according to the manufacturer's recommendations.

Royal Canin Diabetic Feline – an industrial diet designed specifically for cats with diabetes on the background of obesity.

Royal Canin Diabetic DS37 food is recommended for continuous use in dogs with diabetes throughout life. Because the use of this food in dogs significantly increases insulin sensitivity, it is important to monitor blood glucose levels to adjust the dose of insulin. The daily recommended feeding rate into two portions.

The main pathogenetic therapy for animals with diabetes for both domestic cats and dogs is the mandatory use of insulin. Researching the market of drugs in Ukraine, we chose the most affordable and effective veterinary drug – Caninsulin.

The dose of insulin was selected individually for each animal by plotting a curve of blood glucose concentration over three days.

The beginning of therapy was started with a dose of Caninsulin 0.25 IU/kg twice a day. After insulin, cats were given half the daily dose of food for one hour after each injection. Urine tests were performed once a week, and blood tests were performed 3 times for the first three to five days with an interval of 6–8 hours, and the insulin dose curve was established. Ideal: 9:00 – 12.0–18.0 mmol/l; 15:00 – 6.0–10.0 mmol/l; 21:00 – 12.0–18.0 mmol/l.

It should be noted that blood glucose levels do not show the duration of hyperglycemia. Selecting a dose of insulin based on urine parameters can be dangerous. The presence of glucose in the urine indicates only that at some point the concentration of glucose in the blood was above the renal threshold (Lokes-Krupka & Tsvilikhovskyy, 2019).

A possible complication of insulin therapy in the initial stages of treatment may be hypoglycemia. In such cases, there is an increase in appetite, weakness, muscle tremor, anxiety, blood glucose below 6 mmol / l, which is critical for the animal. In this case, cats and dogs were immediately fed sugar syrup. After selecting an individual dose of the drug, the clinical picture stabilized.

At the beginning of treatment and at the end of the course, we conducted a comprehensive study of animals of both species. The results are shown in tables 1–2.

Table 1
Clinical manifestations of diabetes mellitus on the background of obesity in a cats before and after treatment

| Clinical sign                                      | At the beginning of treatment, n = 12 | 30 days after treatment, n = 12 |
|---------------------------------------------------|--------------------------------------|---------------------------------|
|                                                   | animals | % | animals | %        |
| Overweight, obesity                               | 12      | 100.0 | 10      | 83.3     |
| Rapid fatigue                                     | 9       | 75.0  | 6       | 50.0     |
| Dyspnea                                           | 6       | 50.0  | 4       | 33.3     |
| Drowsiness                                        | 6       | 50.0  | 4       | 33.3     |

| Anemia of mucous membranes                        | 9       | 75.0  | 3       | 25.0     |
| Polyuria                                          | 10      | 83.3  | 2       | 16.6     |
| Weight loss                                       | 0       | 0.0   | 1       | 8.3      |
| Vomiting                                          | 3       | 25.0  | 0       | 0.0      |
| Bradycardia                                       | 2       | 16.6  | 0       | 0.0      |
| Hypothermia                                       | 3       | 25.0  | 0       | 0.0      |
| Eye diseases (corneal dystrophy)                  | 0       | 0.0   | 0       | 0.0      |

In cats, the general condition significantly improved as a result of treatment: only one animal remained depressed, the number of cases of hyporexia decreased, only 25.0 % of animals remained pale mucous membranes; temperature within the physiological norm; vomiting and bradycardia were not reported. However, significant weight loss was observed in only one animal, indicating the need to continue treatment. A decrease in the rate of shortness of breath and drowsiness also indicates an improvement in the condition of cats with obesity due to diabetes.

Analyzing the data in Table 2, it can be argued about improving the general state of domestic dogs. As the pathology is characterized by chronicity of the process, there is dullness and wrinkling of the fur in 88.9% of experimental dogs at the beginning of treatment and 22.2 % of animals 30 days after it, which is 4 times lower than at the beginning of treatment. On the improvement of animal health as evidenced restore appetite in 66.7 % of domestic dogs. Only one dog had anemia of the mucous membranes. Anxiety, bradycardia, hypothermia and itching disappeared completely. However, obesity
decreased by only 11.1%, ie in one month there was a tendency to decrease the body weight of animals, but due to the insufficient duration of treatment, their fatness still remained excessive. Only one dog had polyuria and polydipsia after treatment. Vomiting was not recorded in dogs for 1 month of diet therapy.

Table 2
Clinical manifestations of diabetes mellitus on the background of obesity in dogs before and after treatment

| Clinical sign                              | At the beginning of treatment, n = 9 | %   | 30 days after treatment, n = 9 | %   |
|--------------------------------------------|--------------------------------------|------|--------------------------------|------|
| Overweight, obesity                        | 9                                    | 100.0| 8                              | 88.9 |
| Rapid fatigue                              | 4                                    | 44.4 | 2                              | 22.2 |
| Dyspnea                                    | 4                                    | 44.4 | 1                              | 11.1 |
| Drowsiness                                  | 3                                    | 33.3 | 2                              | 22.2 |
| Violation of the condition of the coat     | 8                                    | 88.9 | 2                              | 22.2 |
| (hair wrinkling, xerosis)                  |                                      |      |                                |      |
| Lameness                                   | 0                                    | 0.0  | 0                              | 0.0  |
| Hypo / anorexia                            | 8                                    | 88.9 | 2                              | 22.2 |
| Polydipsia                                 | 6                                    | 66.7 | 1                              | 11.0 |
| Itch                                       | 2                                    | 22.2 | 1                              | 11.1 |
| Depressed state                            | 5                                    | 55.5 | 1                              | 11.1 |
| Anxious state                              | 4                                    | 44.4 | 0                              | 0.0  |
| Anemia of mucous membranes                 | 7                                    | 77.8 | 1                              | 11.1 |
| Polyuria                                   | 7                                    | 77.8 | 1                              | 11.1 |
| Weight loss                                | 0                                    | 0.0  | 0                              | 0.0  |
| Vomiting                                   | 2                                    | 22.2 | 0                              | 0.0  |
| Bradycardia                                | 2                                    | 22.2 | 0                              | 0.0  |
| Hypothermia                                 | 2                                    | 22.2 | 0                              | 0.0  |
| Eye diseases (corneal dystrophy)           | 0                                    | 0.0  | 0                              | 0.0  |

Conclusions
Therefore, our proposed treatment scheme for a domestic cat with diabetes mellitus on the background of obesity is effective, but needs further application. Animals of both species are recommended for life to follow a diet. Continuous supervision of the animal by a veterinarian and periodic re-laboratory tests are mandatory.

Prospects for further research. In further research, we will conduct a comparative analysis of functional and structural changes in the internal organs of domestic dogs in different types of obesity, as well as determine the effectiveness of correction of the pathological condition of animals.

Conflict of interest
The authors declare that there is no conflict of interest.
