**ABSTRACT:** Tuberculosis remains a major cause of mortality and morbidity, killing each year more than one million people. Although the combined use of first line antibiotics (isoniazid, rifampicin, pyrazinamide, and ethambutol) is efficient to treat most patients, the rapid emergence of multidrug resistant strains of *Mycobacterium tuberculosis* stresses the need for alternative therapies. Mycobacterial transcriptional repressor EthR is a key player in the control of second-line drugs bioactivation such as ethionamide and has been shown to impair the sensitivity of the human pathogen *Mycobacterium tuberculosis* to this antibiotic. As a way to identify new potent ligands of this protein, we have developed fragment-based approaches. In the current study, we combined surface plasmon resonance assay, X-ray crystallography, and ligand efficiency driven design for the rapid discovery and optimization of new chemotypes of EthR ligands starting from a fragment. The design, synthesis, and in vitro and ex vivo activities of these compounds will be discussed.

**INTRODUCTION**

Tuberculosis (TB) remains a major cause of mortality and morbidity, killing each year about 1.3 million people. Although the combined use of first line antibiotics (isoniazid, rifampicin, pyrazinamide, and ethambutol) is efficient to treat most patients, the rapid emergence of multidrug resistant strains of *Mycobacterium tuberculosis* stresses the need for alternative therapies. Mycobacterial transcriptional repressor EthR is a key player in the control of second-line drugs bioactivation such as ethionamide and has been shown to impair the sensitivity of the human pathogen *Mycobacterium tuberculosis* to this antibiotic. As a way to identify new potent ligands of this protein, we have developed fragment-based approaches. In the current study, we combined surface plasmon resonance assay, X-ray crystallography, and ligand efficiency driven design for the rapid discovery and optimization of new chemotypes of EthR ligands starting from a fragment. The design, synthesis, and in vitro and ex vivo activities of these compounds will be discussed.

fully succeeded in delivering a substantial quantity of lead compounds to enrich the pipeline.\textsuperscript{5,6} In parallel, fragment-based drug design (FBDD) has become an established approach in medicinal chemistry to discover hits and lead compounds in many areas\textsuperscript{7,8} and particularly in infectious diseases, where conventional techniques may have failed. FBDD strategies were used for the discovery of inhibitors of \textit{M. tuberculosis} proteins such as the tyrosine phosphatases \textit{PtpA}\textsuperscript{9,10} and \textit{PtpB}, \textsuperscript{11} pantothenate synthetase,\textsuperscript{12} antigen \textit{85C},\textsuperscript{13} and \textit{CYP121}.\textsuperscript{14,15} However, none of these examples led to compounds showing whole cellular activities. More recently, Tran et al. discovered and optimized aromatic fragment-based inhibitors of type II dehydroquinase that inhibit the growth of \textit{M. tuberculosis} in the low-micromolar range.\textsuperscript{16} Finally, Surade et al. used a structure-guided fragment linking strategy to discover an EthR ligand able to boost ethionamide activity when tested at 1 μM.\textsuperscript{17}

One of the major advantages to use fragments as starting molecules relies on their small size (usually less than 17 non-hydrogen atoms) and low molecular weight (MW < 300 g mol\textsuperscript{-1}). They exhibit therefore better physicochemical properties, especially solubility, than lead-like or drug-like compounds. Because \textit{M. tuberculosis} is an intracelular pathogen, these properties make fragments ideal tools to favor their penetration into the phagosomes of macrophages that harbor the bacteria and eventually through the waxy and thick \textit{M. tuberculosis} cell wall itself.\textsuperscript{18} This fundamental advantage compensates for low affinity and activity of initial hit fragments which can be optimized in a second round of synthesis, keeping molecular weight and size as low as possible while improving ligand efficiency.

In the present study, we searched for new potent chemical series of EthR ligands and ethionamide boosters using fragment-based approaches. Ethionamide is a second-line drug used to treat MDR-TB that is resistant to both first-line drugs isoniazid and rifampicin. It is a prodrug bioactivated by the \textit{M. tuberculosis} flavin-containing monoxygenase EthA that triggers the formation of an ethionamide–NAD adduct.\textsuperscript{19} This active ethionamide–NAD adduct inhibits InhA and thus the synthesis of mycolic acids. EthR, a transcriptional repressor of the TetR family that inhibits the expression of EthA, was identified as the major factor of the mycobacterial molecular mechanism contributing to intrinsic ethionamide low activity.\textsuperscript{20,21} Recently, we demonstrated that EthR is a valuable target to boost ethionamide bioactivation. We identified potent drug-like EthR ligands that boost in vitro and in vivo ethionamide activity using structure-based design\textsuperscript{22–24} and high-throughput screening.\textsuperscript{25} We ended up with two distinct families of ligands, one bearing an acylated 1,2,4-oxadiazolylpiperidinyl scaffold and the second one presenting a \textit{N}-phenylphenoxyacetamide motif. Representative members of

\end{figure}
the two series, compounds 1 (BDM31369) and 2 (BDM31827), were successfully cocrystallized with EthR at a resolution of 2.0 Å. The two ligands occupy the same region of the ligand binding domain and are both H-bonded to Asn179. Compound 2 also binds to the side chain of Asn176 (Figure 1). This structural information was used to further explore the ligand binding domain of EthR. Starting from a small EthR ligand and using a combination of X-ray crystallography, in silico screening, as well as fragment-growing, merging, and linking approaches, we discovered a new chemical family of potent EthR ligands. We succeeded in improving by 400-fold activity of our initial fragment thanks to key modifications. This work led to the rapid discovery of compound 19 (BDM43266), which displays high efficacy through a new binding mode.

## RESULTS AND DISCUSSION

4-Iodo-N-prop-2-ynylbenzenesulfonamide (compound 3) is a small molecule that was discovered while probing the flexibility of the long and linear ligand binding domain of EthR using in situ click-chemistry. The compound 3 can be considered as a fragment as it follows the “rule of 3” (Table 1), with less than 3 H-bond acceptor and H-bond donor atoms, a calculated logP less than 3, 14 heavy atoms, and a low molecular weight (<300 g·mol⁻¹) without taking the mass of iodine atom into account. Interestingly, it also displayed a very high solubility (>200 μM).

Moreover, the compound 3 was confirmed as a weak binder of EthR. Using the thermal shift assay developed earlier to evaluate the affinity of ligands to EthR, we measured a shift of temperature between holo and apo-EthR, expressed as ΔTm of 0.1 °C. Its capacity to inhibit EthR–DNA interaction, measured by surface plasmon resonance assay (SPR), was not negligible as it showed an IC₅₀ equal to 160 μM. More importantly, the binding mode of the compound 3 to EthR was revealed by cocrystallization with the protein. The structure of the complex was determined at a resolution of 2.0 Å. X-ray analysis of the crystal structure revealed the presence of two copies of the compound 3 embedded in each binding pocket of the homodimeric structure of EthR (Figure 2).

The binding domain filled by the two molecular entities adopts a “Y-like” shape with three distinct subdomains called D1, D2, and D2’. D1 represents the “known binding domain”, where all described EthR ligands have been shown to fit. This hydrophobic pocket is lined with backbones of Phe110, Phe114, Met142, Ile107, and Trp207, and displays at the bottom a gate formed by the side chains of Trp138 and Phe184. These two residues have been shown to delimit a secondary pocket of the protein accessible to longer ligands. In this D1 domain, the compound 3 is sandwiched between Trp207 and Phe110, while its sulfonamide group is H-bonded to Asn179. The newly occupied subpocket D2 is defined by backbones of Met102, Trp103, Val152, and Tyr148 that is H-bonded to the sulfonamide moiety of the second molecule of the compound 3. The sulfonamide nitrogen of the fragment also participates in water-mediated interactions with Leu90 and Asn93. Finally, a third subpocket D2’ composed by Pro94, Thr105, Ala95, and Leu90 is invaded by the acetylenic tail. The original binding of the compound 3 in two distinct pockets of the ligand binding domain of EthR was

a nice opportunity to optimize this small fragment, either by starting a growing strategy or by linking two scaffolds together. The fragment-growing strategy was focused on pocket D1 and initiated with a fragment evolution using the synthesis of a virtual library based on the arylsulfonamide scaffold to allow the introduction of a broad diversification of the starting molecule. On the basis of structural data, rational chemical modifications were performed and compounds were validated throughout the optimization process as EthR ligands using SPR. Impacts of modifications on binding mode were confirmed by X-ray diffraction of crystals of holo-protein complexes. In parallel, fragment merging and linking strategies were performed to design compounds that not only bind to subpocket D1 but also interact with new defined subpockets D2 and D2′.

**Fragment Growing Strategy.** Following the identification of the compound 3, we performed its chemical optimization using a fragment growing approach with the aim of improving ligand efficiency. As we knew from past studies that anchoring via H-bond to Asn179 and occupancy of the ligand binding domain near Gly106 is crucial for EthR inhibition, we focused our growing-based optimization on the design of molecules that could target the D1 pocket. To guide the design of potent analogues, we built a virtual library of 976 members based on arylsulfonamide framework, the key molecular feature that allows compound 3 to interact in the D1 pocket. As this ligand binding domain is thin and linear, the chemical diversity was introduced in two opposite directions. We virtually modified the nature of the sulfonamide chain by introducing small hydrophobic substituents, and we allowed larger modifications at the para position of the phenyl ring. The library was synthesized in silico by coupling 16 small amines (MW > 100 g·mol⁻¹) with 61 commercially available 4-substituted arylsulfonamide chlorides using the Accelrys software Pipeline Pilot (Figure 3).

We then developed an in silico docking procedure that took into account the previously acquired knowledge on interactions between EthR and its ligands. The occupancy of pockets D2 and D2′ by the compound 3 (EthR-3) was a yet undescribed structural feature, whereas the occupation of D1 has been described for high affinity ligands cocrystallized previously. This was for example the case for compound 1 (EthR-1, PDB code 3Q0V, Figure 1A), which showed a favorable occupancy of the D1 pocket. To take advantage of these two structures, which collectively allowed an optimized occupancy of the EthR binding pocket for the newly designed compounds of our virtual library, we performed docking on each cocrystal structures of EthR and combined the results. Using the software Surflex 2.415, we docked the 976 members of the virtual library on the two unoccupied conformations of EthR, and we eventually filtered out compounds having a score below a predicted pKi of 8. We obtained 142 ligands coming from the docking on EthR-1 and 148 ligands issued from the docking on EthR-3. We selected from the two lists the 75 ligands that were able to accommodate both conformations of the protein, and we finally inspected manually the docking poses of each fragment to select among the 75 ligands those having favorable protein–ligand contacts such as hydrogen bonds (mainly with the side chain of Asn179) and hydrophobic contacts. Among
the 75 compounds, 10 (1% of the whole library) resulted from sulfonylation of isopentylamine (Figure 3). The docking simulations proposed that the substituted aliphatic chain would fit perfectly at the bottom of D1, which is in agreement with our previous work.23

These 10 compounds (5−14) were selected and synthesized, according to Scheme 1, from the reaction of 10 different arylsulfonyl chlorides with 3-methylbutan-1-amine in the presence of anhydrous N,N-dimethylformamide (DMF). 4-Iodo-N-isopentylbenzenesulfonamide (compound 4), the direct analogue of compound 3, with an isopentyl tail, was synthesized to evaluate the impact of this substitution on in vitro activity. Compounds 3−14 were screened against EthR using the thermal shift assay (Table 2). In agreement with in silico docking, the replacement of the propargyl chain (compound 3) by isopentyl (compound 4) increased melting temperature by 1.8 °C. The replacement of iodine by oxazole, pyrazole, or pyrrolidinone (compounds 7, 9, and 14) did not increase affinity to the target. On the contrary, the replacement of iodine (compound 4) by 2-methylthiazol-4-yl (compound 8) shifted melting temperature by 4.2 °C. Lower increases were observed with the introduction of hydrophobic aliphatic chain (compound 12) or hydrophilic alkyl ester and ether chains (compounds 13 and 11). Addition of a bulkier aromatic ring (compounds 5, 6, and 10) was less tolerated. To evaluate the ability of these compounds to cross biological membranes and to reach their target in a cellular assay, the 10 EthR ligands were tested in vitro on M. tuberculosis infected macrophages. The assay was performed in the presence of subactive concentrations of ethionamide (0.1 μg/mL (normal MIC/10)) to inhibit 50% of M. tuberculosis growth in macrophages. Ligand efficiency index (LE) was used to compare compounds and expressed using the following equation LE = ((1.37 × pEC50)/(HA)) where HA is the number of heavy atoms.29,30

At this stage, three compounds (8, 12, and 13) had EC50 ranging between 5 and 10 μM. Compound 8, the most active analogue in both assays (ΔTm = 6.1 °C, EC50 = 5.7 μM), was successfully cocrystallized with EthR, and the structure was

---

ΔTm data were obtained using thermal shift assay. EC50 represents the concentration of ligand that allows ethionamide at 0.1 μg/mL (normal MIC/10) to inhibit 50% of M. tuberculosis growth in macrophages. HA = number of non-hydrogen atoms.
determined at a resolution of 2.0 Å (Figure 4A). X-ray diffraction data revealed that as predicted by docking (Figure 4B), the sulfonamide group was H-bonded to the side chain of Asn179. The phenyl scaffold was facing Trp207 and Phe110, while the thiazole ring was surrounded by Trp103, Tyr148, Val152, and Leu87. The methyl substituent was pointing to Met102, which had flipped to occupy the subpocket D2. We also observed that the ligand fitted well the bottom of the ligand binding domain as expected.

To improve ligand efficiency, we explored chemical modifications specifically designed to impact weakly on the molecular weight. We kept the 2-methylthiazol-4-yl moiety, and we first replaced the isopentyl chain of the compound 8 by a more substituted 3,3-dimethylbutyl chain or by trifluoroalkylated linear chains (compounds 15–18, Table 3). Increase of steric hindrance in the bottom of the D1 pocket by the introduction of a tert-butyl group led to a loss of activity (compound 15, ∆T_m = 2.3 °C and EC_{50} > 20 μM). Substitution of the isopentyl chain by a trifluoropropyl chain leading to compound 17 increased significantly the affinity (∆T_m = 8.5 °C) and by 20-fold the efficacy (EC_{50} = 0.29 μM, LE = 0.41). Moreover, the fluorinated compound 17 also exhibited an improved solubility (14.5 μg/mL) compared to compound 8 (6.6 μg/mL), in agreement to what was already observed with previous identified EthR ligands or in the literature. Shorter (compound 16) or longer (compound 18) trifluoromethylated analogues were less active (EC_{50} > 2.5 μM). Compound 17 was 9 times more potent than the

\[ dx \]

\[ \Delta T_m \] were obtained using thermal shift assay. IC_{50} were determined by SPR and represents the concentration of ligand that inhibits 50% of the interaction of EthR with its promoter. EC_{50} represents the concentration of ligand that allows ethionamide at 0.1 μg/mL (normal MIC/10) to inhibit 50% of M. tuberculosis growth in macrophages. HA = number of non-hydrogen atoms. LE = −1.37log(EC_{50})/HA. Solubilities were determined at pH 7.4.

Figure 4. (A) X-ray structure of compound 8 (green) cocrystallized with EthR (B). Docked pose of compound 8 (magenta) with X-ray structure of EthR. The root-mean-square deviation (RMSD) between the docked pose and the experimental bioactive conformation of the compound 8 is equal to 1.15 Å. (PDB ID 4M3F) Pivotal hydrogen bonds between the compound 8 and Asn179 are respectively 2.84 and 2.99 Å.
compound 8 in SPR assay (IC$_{50}$ = 0.55 vs 4.9 μM). The X-ray crystal structure of the complex of 17 with EthR was determined at a resolution of 2.20 Å. While the aromatic moiety of the molecule conserves the same binding mode as
compound 8, the terminal trifluoropropyl chain has slightly moved to point toward Phe114 at the bottom of the D1 subpocket (Figure 5A).

To further optimize the potency of our compounds, we replaced the sulfonamide function by an amide linker. The compound 19 (Table 3) showed gains in all activities ($\Delta T_m = 11.2^\circ C$ and $EC_{50} = 80$ nM, LE = 0.47) while keeping equal solubility (14.7 $\mu$g/mL). The IC$_{50}$ value of the compound 19 was also slightly improved (IC$_{50} = 0.40$ $\mu$M) compared to 17 (IC$_{50} = 0.55$ $\mu$M). This increase of activity may be due to the formation of a new H-bond between the hydrogen atom of the amide linker and the oxygen atom of Asn176 side chain as revealed by the X-ray crystal structure of the complex, determined at a resolution of 2.00 Å (Figure 5B). Importantly, this result shows for the second time that an EthR ligand can be stabilized in the EthR pocket by H-bonding to asparagines Asn179 and Asn176 at the same time.25

Combining in silico and X-ray structure guided optimization approaches, we rapidly improved the potency of our initial fragment and identified a very efficient lead compound that increases by 10-fold the activity of ethionamide in M. tuberculosis infected macrophages at a concentration of 80 nM.

**Fragment-Merging and Linking Strategies.** In a further attempt to probe the ligand binding domain of EthR in D2 and D2' subpockets, we superimposed the X-ray structure of the compound 19 with the one of compound 3 binding to D2 and D2' (Figure 6A). As the methyl group of the compound 19 was found to be 2.3 Å distant from the sulfur atom of the fragment, we therefore designed the propylsulfonamide analogue 20 as a merged compound which was supposed to be more flexible and accommodate the D2 subpocket while keeping the H-bond interaction with Tyr148 and at the same time maintaining initial interactions in the D1 pocket with Asn179. Interestingly, we also noticed that the distance between the sulfur atom and the terminal carbon atom of the alkyne chain was almost equal to the distance between the sulfur atom and the C5 carbon of the thiazole ring (as shown in Figure 6). We thus thought that a propargylamine linker could be suitable to connect the phenylsulfonamide function to the para position of 3,3,3-trifluoropropylbenzamide scaffold without losing its initial binding mode. This led to the linked compound 21. The two merging/linking compounds were synthesized according to Scheme 2.

```

Compounds 20 and 21 were evaluated in our different assays (Table 4) and cocrystallized with the protein (respective resolutions were 2.11 and 1.90 Å). As expected, the H-bond between the sulfonamide moiety and the hydroxyl group of Tyr148 was observed for the two analogues (Figure 6B,C). However, they bound in a different manner. Indeed, compound 20 bound one oxygen atom of its sulfonamide group to the Tyr148 as the compound 3 did, while the NH group of the compound 21 is now H-bonded to Tyr148. Moreover, we observed a new interaction between the compound 20 and Met102, which slightly moved its side chain to present its sulfur atom to interact with the NH group of the sulfonamide moiety. In the bottom of the pocket, the amide group of the two compounds was also H-bonded to both Asn176 and 179.

Finally, the two compounds 20 and 21 exhibited improved activities compared to initial fragments. However, these compounds were found to be poorly soluble and less efficient...
Table 4. Activities of Compounds 20 and 21

| Cpd | R' | R   | ΔT_m (°C) | IC<sub>50</sub> (μM) | EC<sub>50</sub> (μM) | HA | LE | Solubility (μg/mL) |
|-----|----|-----|-----------|------------------|------------------|----|----|------------------|
| 20  |    |     | 6.6       | 0.56             | 0.32             | 28 | 0.23 | 1.3             |
| 21  |    |     | 4.2       | 3.9              | 0.23             | 28 | 0.24 | 3.0             |

"ΔT_m" were obtained using thermal shift assay. "IC<sub>50</sub>" were determined by SPR and represents the concentration of ligand that inhibits 50% of the interaction of EthR with its promoter. "EC<sub>50</sub>" represents the concentration of ligand that allows ethionamide at 0.1 μM and represents the concentration of ligand that inhibits 50% of the interaction of EthR with its promoter. "HA" = number of non-hydrogen atoms. "LE" = -1.37log(EC<sub>50</sub>)/HA. "Solubility" was determined at pH 7.4.

than compound 19, optimized through the growing strategy. This lack of solubility is probably due to the increase of the number of hydrophobic atoms, which is unavoidable using merging and linking strategies with a ligand binding domain rich in lipophilic residues.

Even if we succeeded in optimizing potencies of the compounds compared to the initial fragments using the linking and merging strategies, these two strategies failed in affording compounds with high ligand efficiency index. In these strategies, we were facing two problems: a decrease of solubility while increasing number of atoms and functional groups and a limitation in the choice of linkers to connect the two scaffolds while maintaining key interactions. Therefore, in the present case, the growing strategy was shown to provide more diversity than linking and merging strategies to explore the rigid ligand binding domain of this transcriptional regulator.

## CONCLUSION

Through three fragment-based approaches, we optimized a fragment into potent ligands of the mycobacterial transcriptional regulator EthR. This process led to the conversion of a micromolar affinity fragment into low nanomolar affinity ligands of EthR and low nanomolar boosters of ethionamide activity. By combining crystallography studies of the ligand—ligand complexes, in silico design to explore the chemical diversity of compounds, and eventually determination of ligand potency by in vitro and cellular assays, we could follow a rational path of optimization which led to the discovery of optimal EthR ligands. Of the three approaches, the "growing" strategy was particularly successful, leading to a new chemical class of EthR ligands, with compound 19 showing optimized activity (ΔT_m = 11.2 °C, IC<sub>50</sub> = 0.40 μM and EC<sub>50</sub> = 0.08 μM), high ligand efficiency (LE = 0.47), and good solubility. Optimization of the pharmacokinetic properties of the lead to perform in vivo experiments will be reported in due course.

## EXPERIMENTAL SECTION

### Biology, Thermal Shift Assay (TSA).

The fluorescent dye SYPRO Orange (Invitrogen) was used to monitor protein unfolding. The thermal shift assay was conducted in a Lightcyler 480 (Roche). The system contained a heating/cooling device for temperature control and a charge-coupled device (CCD) detector for real-time imaging of the fluorescence changes in the wells of the microplate. The final sample concentrations were 10 μM EthR, 2.5× SYPRO Orange, 1% DMSO, and 20 μM ligand in the EthR buffer (10 mM Tris/HCl, 300 mM NaCl, pH 7.5, 0.1 mM EDTA). The samples were heated from 37 to 85 °C with a heating rate of 0.04 °C/s. The fluorescence intensity was measured at Ex/Em: 465/510 nm. The data were obtained using the algorithmic program WaveMetrics Igor by applying the following designed procedure: the fluorescence intensity of each well/sample is plotted as a function of the temperature. Then, the 1D-numerical derivative of these curves is calculated. At last, the maximum data values, corresponding to the inflection points (T_m), is extracted to give T_m in a table and in a graph.

### IC<sub>50</sub> Determination Using Surface Plasmon Resonance (SPR).

Interactions between EthR and the ethA promoter region were analyzed using "Research Grades Streptavidin-Coated Sensor Chips (Sensor Chip SA, Biacore Inc.)" on a Biacore 3000 instrument (Biacore, Uppsala, Sweden). The 106-bp biotinylated DNA fragment overlapping the ethA/ethR intergenic region was obtained by polymerase chain reaction (PCR), purified by agarose gel electrophoresis, and immobilized onto the SA sensor chip. The biotinylated DNA fragment was injected in one channel of the chip at 150 ng/mL to obtain a 75 resonance unit (RU) stable fixation to immobilized streptavidin. Another channel of the chip was loaded with a biotinylated double-stranded 113-bp long irrelevant DNA fragment (+14 to +127 fragment of the Escherichia coli bla gene PCR amplified using oligonucleotides O-343, TTTCCGTGTCGCCCTTATTCC, and O-344, CCACTCGTGCCACCCAACTTGAT, and pUC18 as substrate). Binding of EthR to the immobilized DNA was performed at 25 °C in 10 mM Tris-HCl (pH 7.5), 200 mM NaCl, 0.1 mM EDTA, 1 mM DTT, and 1% DMSO at a flow rate of 20 μL/min for 3 min. Specific interaction (Supporting Information) between EthR and the 106-bp DNA fragment was defined as the signal difference between both channels. For dose—response curves establishment, the test compounds were serially diluted in the binding buffer containing 590 mM EthR, incubated 5 min at 37 °C, then injected in the Biacore at a flow rate of 20 μL/min for 3 min. Supporting Information values were measured at the end of the injection period and used to calculate the inhibition of protein—DNA interaction. IC<sub>50</sub> values were determined using GraphPad Prism software.

### Intracellular Assay.

Raw264.7 macrophages (10<sup>6</sup> cells) were infected with H37Rv-GFP suspension at a multiplicity of infection (MOI) of 1:1 in 300 mL for 2 h at 37 °C with shaking (100 rpm). After two washes by centrifugation at 1100 rpm for 5 min, the remaining extracellular bacilli from the infected cells suspension were killed by a 1 h amikacin (20 μM, Sigma, A2324-5G) treatment. After a final centrifugation step, 40 μL of M. tuberculosis H37Rv-GFP colonized macrophages were dispensed with the Wellmate (Matrix) into 384-well Evotec plates preplated with 10 μL of compound mixture diluted in DMSO and incubated for 4 days at 37 °C, 5% CO<sub>2</sub>. Macrophages were then stained with SYTO 60 (Invitrogen, S11342) for 1 h followed by plate sealing. Confocal images were recorded on an automated fluorescent ultrahigh-throughput microscope Opera (Evotec). This microscope is based on an inverted microscope architecture that allows imaging of cells cultivated in 96- or 384-well microplates (Evotec). Images were acquired with a 20X water immersion objective (NA 0.70). A double laser excitation (488 and 635 nm) and dedicated dichroic mirrors were used to record green fluorescence of mycobacteria and red fluorescence of the macrophages on two different cameras, respectively. A series of four pictures at the center of each well were taken, and each image was then processed using dedicated image analysis. The percent of infected cells, and the number of cells are the two parameters extracted from images analysis as previously reported. Data of two replicates are average.

### Potency Assay of Test Compounds on M. tuberculosis (Ethionamide Concentration Fixed at 0.1 μg/mL, Serial Dilution of Test Compounds).

Ethionamide (Sigma E6005-5G) is diluted into DMSO to 10 mg/mL, and aliquots are stored frozen at −20 °C. Test compounds are suspended in pure DMSO at a concentration of 40 mg/mL in Matrix tubes and then diluted by a 10-fold dilution to 4 mg/mL in Eppendorf tubes. Ten 2-fold serial dilutions of compounds are performed in DMSO in Greiner 384-well V-shape polypropylene plates (Greiner, no. 781280). Equal volumes (5 μL) of diluted
compounds and of ethanamide are transferred to a 384-well low volume polypropylene plate (Corning, no. 3672). Two independent replicates were done for each setting. On the day of the experiment, 0.5 µL of compound plate is first transferred by EVOBird platform (Evotec) to cell assay plates preplated with 10 µL of assay medium.

**Solvability.** The 10 mM solution (40 µL) in DMSO of the sample was added to 1.960 mL of MeOH or PBS at pH 7.4. The samples were gently shaken for 24 h at room temperature, then centrifuged for 5 min and filtered over 0.45 µm filters. An amount equal to 20 µL of each solution was added to 180 µL of MeOH and analyzed by LC-MS. The solubility was determined by the ratio of mass signal areas PBS/Meloch. These experiments were analyzed using a LC-MS-MS triple-

**Crystal Structure Determination of Ethr Ligand Complexes.** Ethr crystals were produced by the vapor diffusion method as described previously. Crystallization drops were streak seeded. The crystal-

**Chemistry. General Information.** NMR spectra were recorded on a Bruker DRX-300 spectrometer. Chemical shifts are in parts per million (ppm). The assignments were made using one-dimensional (1D)1H and 13C spectra and two-dimensional (2D) HSQC and

**N-sytop-4-methoxybiphenyl-4-sulfonamide (5).** Yield 143 mg of white powder, 71%.1H NMR (300 MHz, CDCl3, 25 °C) δ: 7.89 (d, $\delta^C_2$ = 6.3 Hz, 2H), 7.74 (d, $\delta^C_2$ = 8.8 Hz, 2H), 4.75 (s, $\delta^C_2$ = 8.5 Hz, 5H), 7.60 (d, $\delta^C_2$ = 8.5 Hz, 2H), 7.04 (d, $\delta^C_2$ = 9.2 Hz, 2H), 4.41 (s, 1H), 3.88 (s, 3H), 3.00 (t, $\delta^C_2$ = 7.3 Hz, 2H), 1.62 (n, $\delta^C_2$ = 6.7 Hz, 1H), 1.38 (q, $\delta^C_2$ = 7.4 Hz, 2H), 0.87 (d, $\delta^C_2$ = 6.6 Hz, 6H). MS [M + H]+ m/z 334.

**4-Fluoro-N-isopropylbiphenyl-4-sulfonamide (6).** Yield 71 mg of a yellowish powder, 37%. 1H NMR (300 MHz, CDCl3, 25 °C) δ: 7.92 (d, $\delta^C_2$ = 8.3 Hz, 2H), 7.74 (d, $\delta^C_2$ = 8.8 Hz, 2H), 7.65 (Dd, $\delta^C_2$ = 8.9 Hz, 2H), 7.54 (t, $\delta^C_2$ = 5.2 Hz, 2H), 7.22 (t, $\delta^C_2$ = 8.8 Hz, 2H), 4.43 (s, 1H), 3.01 (t, $\delta^C_2$ = 7.2 Hz, 2H), 1.61 (n, $\delta^C_2$ = 6.7 Hz, 1H), 1.38 (q, $\delta^C_2$ = 7.1 Hz, 2H), 0.87 (d, $\delta^C_2$ = 6.6 Hz, 6H). MS [M + H]+ m/z 329.

**N-sytop-(4-oxazol-5-yl)sulfonylamine (7).** Yield 78 mg of white powder, 44%. 1H NMR (300 MHz, CDCl3, 25 °C) δ: 8.02 (s, 1H), 7.93 (d, $\delta^C_2$ = 8.6 Hz, 2H), 7.84 (d, $\delta^C_2$ = 8.6 Hz, 2H), 7.54 (s, 1H), 4.50 (br s, 1H), 3.00 (t, $\delta^C_2$ = 7.3 Hz, 2H), 1.59 (n, $\delta^C_2$ = 6.7 Hz, 1H), 1.37 (q, $\delta^C_2$ = 7.2 Hz, 2H), 0.86 (d, $\delta^C_2$ = 6.6 Hz, 6H). MS [M + H]+ m/z 295.

**N-sytop-(1H-pyrazol-1-yl)sulfonylamine (8).** Yield 90 mg of white powder, 51%. 1H NMR (300 MHz, CDCl3, 25 °C) δ: 8.09 (dd, $\delta^C_2$ = 2.6 Hz, 7.74 (d, $\delta^C_2$ = 0.6 Hz, 1H), 7.96 (d, $\delta^C_2$ = 9.0 Hz, 2H), 7.91 (d, $\delta^C_2$ = 9.2 Hz, 2H), 7.78 (d, $\delta^C_2$ = 1.5 Hz, 1H), 6.57 (dd, $\delta^C_2$ = 2.6 Hz, 1.8 Hz, 1.45 (br s, 1H), 3.00 (t, $\delta^C_2$ = 7.3 Hz, 2H), 1.60 (n, $\delta^C_2$ = 6.7 Hz, 1H), 1.37 (q, $\delta^C_2$ = 7.2 Hz, 2H), 0.86 (d, $\delta^C_2$ = 6.6 Hz, 6H). MS [M + H]+ m/z 294.

**Ethyl 4-(N-sulfonylamino)benzoate (13).** Yield 109 mg of white powder, 60%. 1H NMR (300 MHz, CDCl3, 25 °C) δ: 8.20 (d, $\delta^C_2$ = 8.7 Hz, 2H), 7.94 (d, $\delta^C_2$ = 8.5 Hz, 2H), 4.46 (br s, 1H), 4.42 (q, $\delta^C_2$ = 7.1 Hz, 2H), 2.99 (m, 2H), 1.59 (n, $\delta^C_2$ = 6.7 Hz, 1H), 1.40 (m, 5H), 0.86 (d, $\delta^C_2$ = 6.6 Hz, 6H). MS [M + H]+ m/z 300.

**N-sytop-4(2-oxopyrrolidin-1-yl)sulfonylamine (14).** Yield 83 mg of white powder, 45%. 1H NMR (300 MHz, CDCl3, 25 °C) δ: 7.85–7.84 (m, 4H), 4.39 (br s, 1H), 3.90 (t, $\delta^C_2$ = 7.0 Hz, 2H), 2.95 (q, $\delta^C_2$ = 6.7 Hz, 2H), 2.63 (t, $\delta^C_2$ = 7.7 Hz, 2H), 2.20 (quint, $\delta^C_2$ = 7.6 Hz, 2H), 1.55 (n, $\delta^C_2$ = 6.3 Hz, 1H), 1.35 (q, $\delta^C_2$ = 7.2 Hz, 2H), 0.86 (d, $\delta^C_2$ = 6.7 Hz, 6H). MS [M + H]+ m/z 311.
subsequently added. The compound was extracted with AcOEt. Organic layers were combined, dried over magnesium sulfate, and concentrated in vacuo.

**N-Isopentyl-4-(2-methylthiazol-4-yl)benzenesulfonamide (8).** Yield 67 mg of a pale-yellow powder, 34%. ¹H NMR (300 MHz, CDCl₃, 25 °C): δ = 8.07 (d, 3J(H,H) = 8.5 Hz, 2H), 7.9 (d, 3J(H,H) = 8.5 Hz, 2H), 7.56 (s, 1H), 4.48 (t, 3J(H,H) = 5.7 Hz, 2H), 2.98 (m, 2H), 2.8 (s, 3H), 1.59 (s, 3J(H,H) = 6.7 Hz, 1H), 1.37 (q, 3J(H,H) = 7.2 Hz, 2H), 0.86 (d, 3J(H,H) = 6.8 Hz, 6H). MS [M + H]⁺ m/z 325. HRMS (m/z) for C₁₉H₂₂N₂O₂S₂ [M + H]⁺ calculated, 349.02978; found, 349.0302.

**4-(2-Methylthiazol-4-yl)-N-(4,4,4-trifluorobutyl)benzenesulfonamide (10).** General procedure (iii) with 4,4,4-trifluorobutylamine (5.57 g, 0.04 mmol), 100 mg (0.37 mmol) of sulfonic chloride, 5 mL of dry DMF, and 198 μL (1.8 mmol) of 4-methylmorpholine. Yield 75 mg of beige powder, 54%. ¹H NMR (300 MHz, CDCl₃, 25 °C): δ = 8.19 (s, 3J(H,H) = 8.6 Hz, 2H), 7.84 (d, 3J(H,H) = 8.6 Hz, 2H), 7.84 (s, 1H), 2.89 (m, 2H), 2.77 (s, 3H), 1.38 (m, 2H), 0.85 (s, 9H). MS [M + H]⁺ m/z 465.

**4-(2-Methylthiazol-4-yl)-N-(3,3,3-trifluoropropyl)benzamide (19).** To a stirred solution of 4-(2-methylthiazol-4-yl)benzoic acid (50.0 mg, 0.23 mmol), 3,3,3-trifluoropropionyl chloride (37.5 mg, 0.25 mmol), HBTU (103 mg, 0.27 mmol), and HOBT (52 mg, 0.34 mmol) in anhydrous DMF (2.5 mL) was added DIEA (119 μL, 0.68 mmol). The mixture was stirred at room temperature for 2 h. DMF was then evaporated in vacuo. The solid was dissolved in EtOAc and washed successively with saturated K₂CO₃, HCl 1N, water, and brine. The organic layer was dried over magnesium sulfate and concentrated in vacuo to give the amide 19 (66.8 mg, 93%) as a white solid. ¹H NMR (300 MHz, CDCl₃, 25 °C): δ = 7.91 (d, 3J(H,H) = 8.5 Hz, 2H), 7.83 (s, 1H). The mixture was stirred at room temperature for 2 h. The mixture was stirred at room temperature for 2 h. DMF was then evaporated in vacuo. The solid was dissolved in EtOAc and washed successively with saturated K₂CO₃, HCl 1N, water, and brine. The organic layer was dried over magnesium sulfate and concentrated in vacuo to give the amide 19 (66.8 mg, 93%) as a white solid. ¹H NMR (300 MHz, CDCl₃, 25 °C): δ = 7.91 (d, 3J(H,H) = 8.5 Hz, 2H), 7.83 (s, 1H). The mixture was stirred at room temperature for 2 h. DMF was then evaporated in vacuo. The solid was dissolved in EtOAc and washed successively with saturated K₂CO₃, HCl 1N, water, and brine. The organic layer was dried over magnesium sulfate and concentrated in vacuo to give the amide 19 (66.8 mg, 93%) as a white solid. ¹H NMR (300 MHz, CDCl₃, 25 °C): δ = 7.91 (d, 3J(H,H) = 8.5 Hz, 2H), 7.83 (s, 1H).

**General Procedure (i) for the Synthesis of Compounds 15, 16, 17, and 18.** The corresponding amine was added to a solution of 4-(2-methylthiazol-4-yl)benzenesulfonamide (4, 141 mg, 0.40 mmol), 4-acetamidophenylboronic acid (109 mg, 0.60 mmol), and PdCl₂(dppf) (38 mg, 0.040 mmol) in DME (2.3 mL). The flask was sealed and stirred under microwave irradiation at 115 °C for 30 min. The mixture was filtered on Celite and concentrated in vacuo. Purification of the residue by preparative HPLC gave compound 10 (108 mg, 75%) as a yellowish solid. ¹H NMR (300 MHz, CDCl₃, 25 °C): δ = 8.07 (d, 3J(H,H) = 8.5 Hz, 2H), 7.91 (d, 3J(H,H) = 8.5 Hz, 2H), 2.72 (t, 3J(H,H) = 7.9 Hz, 2H), 1.66–1.51 (m, 4H), 1.37–1.30 (m, 2H), 0.97 (d, 3J(H,H) = 6.3 Hz, 6H), 0.84 (d, 3J(H,H) = 6.6 Hz, 6H). MS [M + H]⁺ m/z 298.

**N-(4-(N-Isopentylsulfamoyl)biphenyl-4-yl)acetamide (10).** A solution of Na₂CO₃ (69 mg, 0.60 mmol) in water (0.9 mL) was added to a solution of 4-ido-N-isopentylbenzenesulfonamide (4) (141 mg, 0.40 mmol), 4-acetamidophenylboronic acid (109 mg, 0.60 mmol), and PdCl₂(dppf) (38 mg, 0.040 mmol) in DME (2.3 mL). The mixture was stirred at room temperature for 2 h. DMF was then evaporated in vacuo. The solid was dissolved in EtOAc and washed successively with saturated K₂CO₃, HCl 1N, water, and brine. The organic layer was dried over magnesium sulfate and concentrated in vacuo to give the amide 10 (66.8 mg, 93%) as a white solid. ¹H NMR (300 MHz, CDCl₃, 25 °C): δ = 8.19 (s, 3J(H,H) = 8.5 Hz, 2H), 7.83 (d, 3J(H,H) = 8.5 Hz, 2H), 7.76 (s, 1H). The mixture was stirred at room temperature for 2 h. DMF was then evaporated in vacuo. The orange oil was dissolved in EtOAc and washed successively with saturated K₂CO₃ (2x), HCl 1N (2x), and brine (2x). The organic layer was dried over magnesium sulfate and concentrated in vacuo. Purification by flash column chromatography (7.3:6.5:4 cyclohexane–ethyl acetate) gave 4-acetyl-N-(3,3,3-trifluoropropyl)benzamide (20a) (2.98 g, 91%) as a white solid. ¹H NMR (300 MHz, CDCl₃, 25 °C): δ = 8.02–8.00 (d, 3J(H,H) = 8.6 Hz, 2H), 7.87–7.84 (d, 3J(H,H) = 8.6 Hz, 2H), 6.69 (br s, 1H), 3.76–3.70 (q, 3J(H,F) = 6.4 Hz, 2H), 2.63 (s, 3H), 2.60–2.45 (qt, 3J(H,F) = 10.9 Hz, 3J(H,H) = 6.6 Hz, 2H). MS [M + H]⁺ m/z 260.

A solution of 20a (300 mg, 1.16 mmol) in DCE (15 mL) and MeOH (6 mL) was added trimethylphosphoniammonium tribromide (43.61 mg, 1.16 mmol). The mixture was stirred for 1 h at 50 °C. Then 88 mg of trimethylphosphoniammonium tribromide was added, and the mixture was further stirred for 2 h at 50 °C. DCE and MeOH were evaporated in vacuo, and the solid was dissolved in EtOAc and washed with water and brine. The organic layer was then dried over magnesium sulfate and concentrated in vacuo to give the desired 4-(2-bromocacetyl)-N-(3,3,3-trifluoropropyl)benzamide 20b (387 mg, 99%) as a white solid. MS [M + H]⁺ m/z 340.

A solution of 20b (500 mg, 1.48 mmol) in THF on molecular sieve (10 mL) was added N-benzylocarbonylglycine thioamide (332 mg, 1.48 mmol). The mixture was stirred for 3 h at 70 °C. THF was then evaporated in vacuo. The solid was then treated with a solution of HBr at 25% in acetic acid (5 mL) for 1 h at room temperature. Diethyl ether (40 mL) was added, and the solution was cooled to 0 °C. The precipitate was filtered, washed with diethyl ether, and dried to give a light-brown solid, which was used without any further purification. Then 75 mg of this solid was added in a 10 mL round-bottom flask, dissolved in 1.5 mL of DCM, and treated with 4-methylmorpholine (82 μL) and propane-1-sulfonic chloride (20 μL, 0.18 mmol). The mixture was stirred at room temperature for 2 h. Then 20 μL of a new batch of propane-1-sulfonic chloride was added, and the mixture was stirred for one additional hour. DCM was evaporated in vacuo. Purification of the residue by preparative HPLC.
gave the final compound 20 (54 mg, 76%) as a white solid. \(^1\)H NMR (300 MHz, MeOD, 25 °C): \(\delta = 8.05−8.02\) (d, \(J(H,H) = 8.7\) Hz, 2H), 7.95 (s, 1H), 7.89−7.86 (d, \(J(H,H) = 8.7\) Hz, 2H), 6.42 (s, 2H), 3.66−3.62 (t, \(J(H,H) = 7.0\) Hz, 2H), 3.13−3.08 (m, 2H), 2.62−2.46 (q, \(J(H,F) = 11.0\) Hz). \(1^3\)C NMR (75 MHz, MeOD, 25 °C): \(\delta = 170.0, 168.4, 154.1, 137.3, 133.2, 127.4, 126.6\) (q, \(J(C,F) = 275.9\) Hz), 125.9, 115.4, 54.2, 43.7, 33.1 (q, \(J(C,F) = 3.7\) Hz), 32.7 (q, \(J(C,F) = 28.1\) Hz). \(1^3\)C NMR (75 MHz, CDCl\(_3\), 25 °C): \(\delta = 170.0, 168.4, 154.1, 137.3, 133.2, 127.4, 126.6\) (q, \(J(C,F) = 275.9\) Hz), 125.9, 115.4, 54.2, 43.7, 33.1 (q, \(J(C,F) = 3.7\) Hz), 32.7 (q, \(J(C,F) = 28.1\) Hz). \(1^3\)C NMR (75 MHz, CDCl\(_3\), 25 °C): \(\delta = 170.0, 168.4, 154.1, 137.3, 133.2, 127.4, 126.6\) (q, \(J(C,F) = 275.9\) Hz), 125.9, 115.4, 54.2, 43.7, 33.1 (q, \(J(C,F) = 3.7\) Hz), 32.7 (q, \(J(C,F) = 28.1\) Hz).

4-(3-(Phenylsulfonylamido)prop-1-ynyl)-N-(3,3,3-trifluoropropyl)benzamide (21b). In a 25 mL round-bottom flask were subsequently added DCM (8 mL), benzenesulfonyl chloride (200 \(\mu\)mol), CuI (300 mg, 1.58 mmol), dry DMF (7.5 mL), and TEA (874 \(\mu\)L, 5.05 mmol). The mixture was stirred at room temperature for 2 h. DCM was evaporated in vacuo. The residue was dissolved in AcOEt and washed twice with water and once with brine. The organic layer was then dried over magnesium sulfate and concentrated in vacuo. Purification by preparative HPLC gave \(N\)-(prop-2-ynyl)-benzenesulfonamide 21a (238 mg, 78%) as a beige powder.

To a stirred solution of 4-iodobenzoic acid (300 mg, 1.21 mmol), HOBT (33 mg, 0.24 mmol), HBTU (551 mg, 1.45 mmol), and DIEA (840 \(\mu\)L, 4.84 mmol) in DMF over a molecular sieve (10 mL) was added 3,3,3-trifluoropropylhydrochloride (181 mg, 1.21 mmol). The mixture was stirred for 2 h at room temperature. DMF was then evaporated in vacuo. The residue was dissolved in AcOEt and washed with HCl IN, saturated NaHCO\(_3\) and brine. The organic layer was then dried over magnesium sulfate and concentrated in vacuo. Purification by flash column chromatography (8:2 cyclohexane-ethyl acetate) gave 4-iodo-N-(3,3,3-trifluoropropyl)benzamide 21b (318 mg, 77%) as a white powder. \(^1\)H NMR (300 MHz, CDCl\(_3\), 25 °C): \(\delta = 7.80\) (d, \(J(H,H) = 8.5\) Hz, 2H), 7.47 (d, \(J(H,H) = 8.5\) Hz, 2H), 6.34 (br s, 1H), 3.72 (q, \(J(H,F) = 6.3\) Hz, 2H), 2.47 (q, \(J(H,F) = 10.7\) Hz). \(^1^3\)C NMR (75 MHz, MeOD, 25 °C): \(\delta = 170.0, 168.4, 154.1, 137.3, 133.2, 127.4, 126.6\) (q, \(J(C,F) = 275.9\) Hz), 125.9, 115.4, 54.2, 43.7, 33.1 (q, \(J(C,F) = 3.7\) Hz), 32.7 (q, \(J(C,F) = 28.1\) Hz).

In a Schlenk flask were subsequently added 21b (600 mg, 1.75 mmol), 21a (341 mg, 1.75 mmol), PdCl\(_2\)(PPh\(_3\))\(_2\) (61.4 mg, 0.087 mmol), CuI (300 mg, 1.58 mmol), dry DMF (7.5 mL), and TEA (874 \(\mu\)L, 5.05 mmol) under argon. The mixture was stirred at 80 °C overnight, then cooled to room temperature and a AcOEt 1:1 NH\(_4\)Cl\(_{aq}\) mixture (15 mL) was added and stirred at room temperature for 15 min. The organic layer was washed three times with NH\(_4\)Cl\(_{aq}\) then with water and brine. The organic layer was then dried over magnesium sulfate and concentrated in vacuo. Purification by flash column chromatography (S-95—100 EtOAc—DCM) gave compound 21 (311 mg, 43%) as a white powder. \(^1\)H NMR (300 MHz, CD\(_2\)OD, 25 °C): \(\delta = 7.94−7.91\) (m, 2H), 7.69 (d, \(J(H,H) = 8.4\) Hz, 2H), 7.57−7.49 (m, 2H), 7.20 (d, \(J(H,H) = 8.4\) Hz, 2H), 4.06 (s, 2H), 3.61 (t, \(J(H,H) = 7.0\) Hz, 2H), 2.51 (qt, \(J(H,F) = 10.9\) Hz). \(^1^3\)C NMR (75 MHz, CD\(_2\)OD, 25 °C): \(\delta = 169.9, 142.3, 134.9, 133.7, 132.6, 130.1, 128.4, 128.1, 127.7, 87.7, 84.0, 34.5 (q, \(J(C,F) = 3.9\) Hz), 34.0 (q, \(J(C,F) = 28.2\) Hz), 33.9 MS [M + H]+ m/z 411. HRMS (m/z) for C\(_{21}\)H\(_{17}\)F\(_3\)N\(_2\)O\(_3\)S [M − H]− calculated, 409.0844; found, 409.0840.
