Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Precautions and recommendations for orthodontic settings during the COVID-19 outbreak: A review

Khadijah A. Turkistani
Jeddah, Saudi Arabia

Introduction: Coronavirus disease 2019 (COVID-19) is a contagious disease caused by severe acute respiratory syndrome coronavirus (SARS-CoV-2). It emerged as a global pandemic in early 2020, affecting more than 200 countries and territories. The infection is highly contagious, with disease transmission reported from asymptomatic carriers, including children. It spreads through person-to-person contact via aerosol and droplets. The practice of social distancing—maintaining a distance of 1-2 m or 6 ft—between people has been recommended widely to slow or halt the spread. In orthodontics, this distance is difficult to maintain, which places orthodontists at a high risk of acquiring and transmitting the infection. The objective of this review is to report to orthodontists on the emergence, epidemiology, risks, and precautions during the disease crisis. This review should help increase awareness, reinforce infection control, and prevent cross-transmission within the orthodontic facility.

Methods: A comprehensive literature review of English and non-English articles was performed in March 2020 using COVID-19 Open Research Dataset (CORD-19 2020), PubMed, MEDLINE, Scopus, and Google Scholar to search for infection control and disease transmission in orthodontics.

Results: This review emphasizes minimizing aerosol production and reinforcing strict infection control measures. Compliance with the highest level of personal protection and restriction of treatment to emergency cases is recommended during the outbreak. Surface disinfection, adequate ventilation, and decontamination of instruments and supplies following the guidelines are required.

Conclusions: Reinforcing strict infection control measures and minimizing personal contact and aerosol production are keys to prevent contamination within orthodontic settings. Although no cases of COVID-19 cross-transmission within a dental facility have been reported, the risk exists, and the disease is still emerging. Further studies are required. (Am J Orthod Dentofacial Orthop 2020;158:175-81)

By the end of 2019, an outbreak of severe pneumonia of unknown etiology occurred in Wuhan, China. Bats are believed to be the natural hosts of the disease that was transmitted to humans through an intermediate host. Genomic sequencing revealed a pathogen of coronavirus family similar to coronavirus related to severe acute respiratory syndrome (SARS-CoV) and the Middle East respiratory syndrome (MERS-CoV). The new virus was initially referred to as novel coronavirus 2019-nCoV, then as severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) by the International Committee on Taxonomy of Viruses.

This virus possesses higher transmissibility potential compared with SARS-CoV and MERS-CoV, resulting in a “public health emergency of international concern.” The infection is believed to transmit to humans through fomites, person-to-person contact, aerosol, and droplets. The World Health Organization (WHO) declared this viral outbreak a pandemic affecting 693,224 individuals in more than 200 countries and territories, with a total of 33,106 confirmed deaths by March 30, 2020. The highest number of reported cases were in the United States, with the total number doubled in less than 5 days reaching 122,653 confirmed cases. The highest reported deaths were in Italy, reaching 10,781 deaths out of 97,689 confirmed cases with an 11% mortality rate. Patients confirmed with coronavirus disease of 2019 (COVID-19) develop symptoms of lower respiratory tract infection, including fever, coughing, sneezing, vomiting, generalized fatigue, and severe
pneumonia. The disease onset could be mild, moderate, severe, or critical. Symptoms among infected patients vary from being asymptomatic to Acute Respiratory Distress Syndrome, sepsis, septic shock, and multiple organ failures in critical patients with high reported deaths. Several studies have reported cross-transmission of COVID-19 among healthcare workers, including 3,387 confirmed cases and 22 reported deaths. The disease can transmit from one healthcare worker to another, healthcare worker to patient, or patient to patient within the same facility.

Orthodontists may see dozens of patients in a single day. This fact makes strict infection control measures with the highly transmissible SARS-CoV-2 an area of concern. Children comprise the vast majority of orthodontic patients. Studies have reported asymptomatic children infected with COVID-19. The incubation period of this disease is 14 days up to 24 days. The virus is still highly contagious during this latency period. This finding rings the alarm bell of a potential hazard: treating asymptomatic patients and spreading infection within the orthodontic clinic. Furthermore, aerosol generation—a routine occurrence in the orthodontic clinic—is a confirmed route of infection transmission.

Thus, to face this highly contagious infection, it is important to reevaluate infection control measures within the orthodontic practice. The objective of this review is to shed light on SARS-CoV-2 infection and provide insights on risk, precautions, and recommendations within the orthodontic setting. This review will help increase awareness and control cross-contamination among orthodontists, assistants, office staff, and patients during the COVID-19 crisis.

MATERIAL AND METHODS

Considering the recent emergence of COVID-19, this review included publications in English and non-English languages that matched the search terms up to March 19, 2020. Studies were retrieved from the following databases: COVID-19 Open Research Dataset (CORD-19 on March 13th, 2020 was the last published update), PubMed, MEDLINE, Scopus, and Google Scholar. Non-English articles and abstracts were translated.

The main author with the help of a research assistant conducted the search using the following terms: COVID, COVID-19, COVID-2019, 2019-nCoV, SARS-CoV-2, corona, oral, mouth, dental, dentist, dentistry, stomatology, orthodontic, orthodontist, saliva, infection control, contamination, and transmission. Studies included any of the search terms were selected, and duplicates were eliminated. Screening of titles followed by abstracts was performed. Lastly, articles that fall within the scope of this review were included and retrieved in full text. References of those articles were screened as well using the snowballing technique. The findings of the included studies are discussed below.

LITERATURE OVERVIEW

Risk of disease transmission within the orthodontic practice

Dentistry, including orthodontics, requires proximity to patients while performing operatory procedures. Unfortunately, this makes the dental healthcare workers at a high risk of acquiring infectious diseases. The current recommendations for COVID-19 are to avoid person-to-person contact and maintain 1-2 m distance between individuals. This recommendation cannot be optimized in the orthodontic clinic for the nature of the orthodontic operation, which places the orthodontist and the dental assistant at a high risk of acquiring the infection.

In addition, the incubation period of 2019-nCoV infection could reach up to 24 days, while still being contagious during this latency period. This is especially important for the orthodontists who tend to see a high volume of patients in a short period daily. Furthermore, several studies reported asymptomatic carriers, including children, who comprise a high percentage of orthodontic patients, which elevates the risk on the orthodontic team even higher. Although cross-transmission of COVID-19 within a dental facility has not been reported so far, considering the recent onset of the disease and deficiency in data, the risk is still elevated. Previous studies have reported cross-transmission of infection within the dental facilities including Hepatitis B and Hepatitis C. In the United States, orthodontists are ranked the second-highest incidence of acquiring Hepatitis B. Meng et al reported 9 confirmed cases of COVID-19 within dental team members at the School and Hospital of Stomatology, Wuhan University (SHSWH). Although this was possibly an infection from an outside source other than the dental facility, infected personnel could be contagious during their latency period and infect other team members or patients visiting the dental clinic. This possibility brings the importance of taking strict measures to ensure safety and avoid possible transmission within the orthodontic practice.

Possible sources of contamination

1. Patient’s saliva: Studies reported high loads of SARS-CoV-2 in the saliva of infected patients.
Aerosol: Using a high-speed handpiece or ultrasonic scaler during dental cleaning at bonding, bracket repositioning, and debonding visits produces aerosol and splatter in the operatory vicinity. This aerosol could be contaminated with patient’s blood, saliva, or high concentrations of infectious microbes exceeding those produced by coughing or sneezing. Moreover, aerosol containing microbes was found to reach as far as 2 m from the patient’s mouth, with the highest concentrations reported the furthest away from the patient. This finding means microbes could contaminate surfaces throughout the operatory. A study performed using a fluorescent dye with a high-speed handpiece found that the fluorescence dye reached more than 2 ft from the dental chair. The dye was even found in the noses of the operator and assistant, having penetrated their facial protective gear. Another study reported traces of aerosol were found on operators’ scrub jacket sleeves and chest area. The aerosol could contaminate the dental unit waterline, resulting in the spread of infection. Aerosols containing germs of 0.5-10 μm or less can remain airborne longer, increasing the risk of being inhaled and entering deeper areas of the lung, posing a potential infectious hazard. This collectively presents an alarming threat with the highly contagious COVID-19.

Orthodontic supplies and instruments: Although most archwires are packaged and sealed individually, some orthodontists have recycled and reused wires. This is a huge risk of cross-contamination if wires are not thoroughly sterilized. In addition, reusing tried-in orthodontic bands, orthodontic brackets, elastomeric chains, tungsten carbide debonding burs, miniscrews, orthodontic markers, and photographic retractors without proper sterilization and disinfection are tremendous potential hazards. Orthodontic instruments that come in direct contact with patients’ saliva and blood, including band seaters, band removers, scalers, and ligature directors are considered contamination dangers as well. Improper handling and disinfection of such instruments and supplies would compromise infection control measures within the orthodontic practice.

Preventive measures

1. Patient evaluation and screening: In general, it is recommended during the outbreak to postpone any routine appointments and restrict patients’ visits to emergency treatment only. Screening patients for COVID-19 symptoms and recording their body temperature is essential. Updating patient’s medical history and asking targeted questions relevant to COVID-19 before initiating any dental work is mandatory. This includes (1) history of fever (37.3°C or higher) or use of antipyretic medication in the past 14 days; (2) symptoms of lower respiratory tract infection, including dyspnea in the past 14 days; (3) history of travel to a COVID-19 epidemic area in the past 14 days; and (4) history of contact with a confirmed COVID-19 in the past 14 days.

If the patient is a suspected asymptomatic (no symptoms and no fever), then reschedule the appointment and advise the patient to self-quarantine at home for 14 days. It is unlikely that a confirmed COVID-19 with acute symptoms will visit the orthodontic clinic yet if the patient showed any symptoms, reporting and referral to COVID-19 prepared hospital is mandatory (Fig 1).

2. Daily self-evaluation of the dental health care provider is advised. If the orthodontist does not feel well or developed any symptoms, it is prohibited to work and spread infection.

3. Mouth rinse before any procedure using 0.12%-0.2% chlorhexidine gluconate could help minimize the number of microbes within the oral cavity.

4. Personal protective equipment, including facial mask, face shield, eye protection, gowns, and gloves, are essential protective gear during the outbreak. COVID-19 was reported to transmit through contact of the virus with ocular mucosa; thus, any contact with mucosal tissue of the eyes, nose, or mouth should be avoided.

5. Aerosol production should be restricted, and if necessary, particulate respirators such as N95, EU FFP2, or equivalent in addition to face shield are required. Although COVID-19 was categorized as group B infectious disease, the guidelines suggest that healthcare providers perform protective measures similar to those reserved for group A infectious diseases (such as cholera and plague).

6. Reinforcement of hand hygiene measures according to WHO recommendations (washing hands for 20 seconds minimal) is essential to combat this robust microorganism.
7. Training of the orthodontic team on disease symptoms, routes of transmission, infection control measures, and keeping up with regulation updates are beneficial during SARS-CoV-2 infection crisis.23,47,48,50

8. Adequate ventilation of the operatory and waiting area with new air, high airflow, or with air filters is advised, with special attention to minimizing the number of patients in the waiting area and allowing adequate space for social distancing.6,50,54

9. The operation room could be contaminated with droplets and aerosol. A recent study reported SARS-CoV-2 viability up to 3 hr in aerosol, with a half-life of 5.6 hr on stainless steel and 6.8 hr on plastic surfaces.55 Therefore, strict surface disinfection protocol should be applied after every patient.

10. Medical wastes during the outbreak should be handled as infectious medical wastes. Double-layer yellow antileakage medical waste marked with a special tag is recommended.2,47,56,57

**Orthodontic supplies and instruments**

The following are recommendations to reduce the risk of cross-contamination and help protect vulnerable patients as well as the orthodontic staff.

1. Orthodontic pliers can be sterilized with steam autoclave sterilization, ultrasound bath and thermal disinfection, or disinfected with chemical substances 2% glutaraldehyde or 0.25% peracetic acid. Instrument cassettes can be effectively used, with pliers preferably sterilized in an open position.58-63

---

**Fig 1.** Patient screening flowchart.
2. An autoclave is preferred over cold sterilization, without negatively affecting surface characterization of archwires.15,20,60,64,65
3. Orthodontic markers can be autoclaved or disinfected using glutaraldehyde solution.43,66
4. Cleaning photographic retractors with washer-disinfector were reported as the most effective method of decontamination.67
5. Tungsten carbide debonding burs could be effectively decontaminated from bacterial infection.68
6. It is safe to use tried-in orthodontic bands after adequate precleaning and sterilization.41,69,70
7. Decontamination does not jeopardize clinical stability of miniscrews nor mechanical properties of elastomeric chains.42,71
8. Flushing dental unit waterline for at least 2 min or using disinfectants improves the quality of water within the dental unit and minimize the risk of infection.22,23

CONCLUSIONS

In summary, SARS-CoV-2 is the first highly contagious pandemic infection of this millennium. Although cross-contamination within any dental setting has not been reported, dentists in all disciplines, including orthodontists, need to be constantly aware of the emerging infectious threats and informed of updates in infection control guidelines. The findings of this review reinforce the importance of good work practices, including hygiene, infection control, and personal protection. Given the high transmissibility of COVID-19, controlling aerosol and human-to-human contact while limiting treatment to emergency patients only is advised during the outbreak. It is the responsibility of the orthodontic team to ensure safety and stop cross-contamination within the clinical facility. Finally, the impact of COVID-19 on the orthodontic practice, cost of illness, and whether clear aligners that require mini-implants nor mechanical properties of miniscrews nor mechanical properties of elastomeric chains.42,71
