ABSTRACT
Introduction: Hyperthyroidism causing pseudotumor cerebri is very rare in children. Case Report: We are reporting a case of a 17-year-old girl with uncontrolled Graves’ disease presenting with pseudotumor cerebri (PTC). Patient initially did not respond to common management of PTC with therapeutic lumbar puncture and acetazolamide, but improved after treating hyperthyroidism by radioablation therapy. Conclusion: We emphasize that uncontrolled hyperthyroidism should be suspected as a secondary cause of pseudotumor cerebri in children and treated aggressively to avoid its dreaded complications.

Keywords: Pseudotumor cerebri (PTC), Benign intracranial hypertension (BIH), Graves’ disease, Papilledema, Radioablation therapy, Hyperthyroidism

CASE REPORT
A 17-year-old African-American female with congenital HIV controlled on anti-retroviral therapy (Complera, Gilead Sciences, Inc. Foster City, CA, USA), mild intermittent asthma and Graves’ disease diagnosed five years ago, managed by methimazole with poor compliance, presented with one day history of severe pounding bi-frontal headache unrelieved by analgesics. There was no history of vomiting, fever, visual problems, weakness of extremities, seizures, neck stiffness, or trauma. On examination, patient had tachycardia and
other vital signs were normal. Her weight was 48 kg and body mass index was 19.3 kg/m². Her physical examination showed diffuse enlargement of the thyroid gland and exophthalmos. On neurological examination, there was bilateral papilledema without any focal neurological deficit or altered sensorium. Computed tomography (CT) scan of head was normal. On lumbar puncture, her CSF opening pressure was raised (430 mm of H₂O), no cells, with normal glucose and protein levels. The CSF was removed therapeutically which did not relieve her headache significantly. The CSF studies were negative for any bacteria, fungi, or viruses. Repeat magnetic resonance imaging (MRI) scan of brain with and without contrast was normal except for the finding of stable cerebellar tonsillar ectopia which was consistent with the previous MRI. Cerebral vascular thrombosis was ruled out by magnetic resonance venography (MRV) and magnetic resonance angiography (MRA) studies.

Blood analysis showed thyroid stimulating hormone (TSH) level <0.1 µIU/mL (normal limits 0.35–4.94 µIU/mL), FT₄ 2.5 ng/dL (normal limits 0.9–1.5 ng/dL), total T₄ 17.7 µg/dL (normal limits 4.8–1.7 µg/dL) and total T₃ 310 ng/dL (normal limits 60–160 ng/dL). Thyroid uptake study was consistent with diffuse toxic goiter with increased uptake 74.3% compared to the previous study 61%.

Patient was initially treated with atenolol, acetazolamide and other supportive measures, which only partially relieved her symptoms. Patient received radioablation therapy with 15 mCi of I-131 and reported to feel better. She was followed up in pediatric endocrinology clinic one month after radioablation therapy and found to be asymptomatic. Her thyroid functions were slowly recovering (Table 1).

Table 1: Changes in thyroid function test with treatment

| Thyroid Function Tests | Prior to Radioablation therapy | 4 weeks after therapy | 6 weeks after therapy |
|------------------------|-------------------------------|-----------------------|-----------------------|
| TSH (µIU/mL)           | <0.1                          | <0.1                  | <0.1                  |
| Total T₄(µg/dL)        | 17.7                          | 12                    | 10.9                  |
| Free T₄ (ng/dL)        | 2.5                           | 1.7                   | 1.4                   |
| Total T₃ (ng/dL)       | 310                           | 230                   | 180                   |

**DISCUSSION**

Hyperthyroidism causing PTC is rare in children with only 2 reported cases [2, 3]. In one report, hyperthyroidism was associated with hypovitaminosis A. We excluded other causes of raised intracranial pressure in our patient and confirmed the diagnosis of PTC. Although acetazolamide can cause symptomatic relief of PTC, our patient mostly improved after radioablation therapy of thyroid. Therefore, we concluded that PTC was associated with Graves’ disease in this case. This was also supported by improvement in her thyroid hormone levels along with symptomatic relief.

The pathophysiologic basis of PTC is still not clearly understood, but a relationship has been established with elevated intracranial venous pressure [4, 5]. The increase in resistance of CSF absorption is thought to be caused by an insufficiently high driving pressure gradient from the subarachnoid space to the venous system. Thyroxine, being a major regulator of sodium transport, can contribute to altered CSF dynamics [6]. The effect of thyroid hormone raising venous pressure may justify the association between those two entities [6].

**CONCLUSION**

We would like to emphasize that uncontrolled Graves’ disease should be considered as a rare secondary cause of pseudotumor cerebri in children. Hyperthyroidism should be treated aggressively to reduce the complications associated with pseudotumor cerebri, most notably permanent visual impairment.
