Abstract

If the atmospheric neutrino oscillation amplitude, $\sin^2 2\theta_{\text{ATM}}$ is not maximal, there is a two fold ambiguity in the neutrino parameter space: $\sin^2 2\theta_{\text{ATM}} > 0.5$ or $\sin^2 2\theta_{\text{ATM}} < 0.5$. In this article, we study the impact of this degeneracy, the so-called octant degeneracy, on the T2KK experiment, which is a proposed extension of the T2K (Tokai-to-Kaimoka) neutrino oscillation experiment with an additional water Čerenkov detector placed in Korea. We find that the degeneracy between $\sin^2 2\theta_{\text{ATM}} = 0.40$ and 0.60 can be resolved at the $3\sigma$ level for $\sin^2 2\theta_{\text{RCT}} > 0.12$ (0.08) for the optimal combination of a 3.0° off-axis beam (OAB) at SK ($L = 295$km) and a 0.5° OAB at $L = 1000$km with a far detector of 100kton volume, after 5 years of exposure with $1.0 \times 10^{21}$ POT/year, if the hierarchy is normal. We also study the influence of the octant degeneracy on the capability of T2KK experiment to determine the mass hierarchy and the leptonic CP phase. The capability of rejecting the wrong mass hierarchy grows with increasing $\sin^2 2\theta_{\text{ATM}}$ when the hierarchy is normal, whereas it is rather insensitive to $\sin^2 2\theta_{\text{ATM}}$ for the inverted hierarchy. We also find that the 1σ allowed region of the CP phase is not affected significantly even when the octant degeneracy is not resolved. All our results are obtained for the 22.5 kton Super-Kamiokande as a near detector and without an anti-neutrino beam.

1 Introduction

A decade ago, it was difficult to believe that neutrinos have mass and the lepton flavor mixing matrix, the Maki-Nakagawa-Sakata (MNS) matrix \cite{ref1}, has two large mixing angles \cite{ref2}- \cite{ref7}. Within the three neutrino framework, 2 mass-squared differences, 3 mixing angles, and 1 CP phase can be resolved by neutrino oscillation experiments. So far, the magnitude of the larger mass-squared difference, the magnitude and the sign of the smaller one, two of the three mixing
angles, and the upper bound of the third mixing angle have been known. The sign of the larger mass-squared difference (the mass hierarchy pattern), the magnitude of the third mixing angle ($\theta_{\text{RCT}}$), and the leptonic CP phase ($\delta_{\text{MNS}}$) are yet to be measured.

In the previous papers [8, 9], we studied in detail the physics impacts of the idea [10] of placing a far detector in Korea along the T2K neutrino beam line. For concreteness we examined the effects of placing a 100kton water Čerenkov detector in Korea, about $L = 1000\text{km}$ away from J-PARC (Japan Proton Accelerator Research Complex) [11], during the T2K (Tokai-to-Kamioka) experiment period [12], which plans to accumulate $5 \times 10^{21}$ POT (protons on target) in 5 years. We find that this experiment with two detectors for one beam, which may be called the T2KK experiment [13], can determine the mass hierarchy pattern, by comparing the $\nu_\mu \to \nu_e$ transition probability measured at Super-Kamiokande (SK) and that at a far detector in Korea. Moreover, both the sine and cosine of the CP phase can be measured from the energy dependence of the $\nu_\mu \to \nu_e$ oscillation probability, which can be measured by selecting the quasi-elastic charged current events. By studying these physics merits of the T2KK experiment semi-quantitatively, we find an optimal combination of a $3^\circ$ off-axis beam (OAB) at SK and a $0.5^\circ$ OAB in the east coast of Korea at $L = 1000\text{km}$, for which the mass hierarchy and the CP phase ($\delta_{\text{MNS}}$) can be determined without invoking an anti-neutrino phase [8, 9], when the mixing angle $\theta_{\text{RCT}}$ is not too small. In the related study [14], a grander prospect of the T2KK idea has been explored, where two identical huge detectors of several 100kton volume is placed in Kamioka and in Korea, and the future upgrade of the J-PARC beam intensity has also been considered. The idea of placing two detectors along one neutrino beam has also been explored for the Fermi Lab. neutrino beam [15].

In this report, we focus on the yet another degeneracy in the neutrino parameter space, which shows up when the amplitude of the atmospheric neutrino oscillation, $\sin^2 2\theta_{\text{ATM}}$, is not maximal. Hereafter, we call this degeneracy between $\sin^2 2\theta_{\text{ATM}} > 0.5$ and $\sin^2 2\theta_{\text{ATM}} < 0.5$, or between “90° − $\theta_{\text{ATM}}$” and “$\theta_{\text{ATM}}$”, as the octant degeneracy [16].

Since the best fit value of the mixing angle $\theta_{\text{ATM}}$ is 45° [2, 3, 4], we set $\sin^2 2\theta_{\text{ATM}} = 1$ in all our precious studies [8, 9], and hence we did not pay attention on physics impacts of the octant degeneracy. However, we are concerned that the octant degeneracy affect the capability of the T2KK experiment for the mass hierarchy determination and the CP phase measurement, because the leading term of the $\nu_\mu \to \nu_e$ oscillation probability is proportional to $\sin^2 \theta_{\text{ATM}}$, not $\sin^2 2\theta_{\text{ATM}}$. If the value of $\sin^2 2\theta_{\text{ATM}}$ is 0.99, which is 1% smaller than the maximal mixing, the value of $\sin^2 \theta_{\text{ATM}}$ is 0.45 or 0.55, which differ by 20%.

For $\sin^2 2\theta_{\text{ATM}} = 0.92$, which is still allowed at the 90% CL [2, 3, 4], $\sin^2 \theta_{\text{ATM}} = 0.64$ or 0.36, which differ by almost a factor of two. Therefore, we also examine impacts of varying $\sin^2 \theta_{\text{ATM}}$ on the mass hierarchy determination and the CP phase measurement by T2KK. In our semi-quantitatively analysis, we follow the strategy of ref.[8, 9] where we adopt SK as a near side detector and postulate a 100 kton water Čerenkov detector at $L = 1000\text{km}$, and the J-PARC neutrino beam orientation is adjusted to 3.0° at SK and 0.5° at the Korean detector site.

This article is organized as follows. In section 2, we fix our notation and show how the octant
degeneracy affects the oscillation probabilities. In section 3, we review our analysis method and present an explicit form of the $\Delta \chi^2$ function which we use to measure the capability of the T2KK experiment semi-quantitatively. In section 4, we show the results of our numerical calculation on the resolution of the octant degeneracy. In section 5, we examine the capability of the T2KK experiment for the mass hierarchy determination, in the presence of the octant degeneracy. We also show the effect of the octant degeneracy on the CP phase measurement in section 6. In the last section, we summarize our results and give discussions.

2 Oscillation formulas and experimental bound

When a neutrino of flavor $\alpha$ is created at the neutrino source with energy $E$, it is a mixture of the mass eigenstates, $\nu_i$

$$|\nu_\alpha\rangle = \sum_{i=1}^{3} U_{\alpha i} |\nu_i\rangle, \quad (\alpha = e, \mu, \tau)$$

(1)

where $U_{\alpha i}$ is the element of the Maki-Nakagawa-Sakata (MNS) matrix [1]. Without losing generality, we can take $U_{e2}$ and $U_{\mu3}$ to be real and non-negative and allow $U_{e3}$ to have a complex phase $\delta_{\text{MNS}}$ [17, 18].

After traveling the distance $L$ in the vacuum, a neutrino flavor eigenstate $|\nu_\beta\rangle$ is found with the probability

$$P_{\nu_\alpha \rightarrow \nu_\beta} = |\langle \nu_\beta | \nu_\alpha(L) \rangle|^2 = \left| \sum_{j=1}^{3} U_{\alpha j} \exp \left( -\frac{m_j^2}{2E} L \right) U_{\beta j}^* \right|^2$$

$$= \delta_{\alpha \beta} - 4 \sum_{i>j} \Re(U_{\alpha i}^* U_{\beta i} U_{\alpha j} U_{\beta j}^*) \sin^2 \frac{\Delta_{ij}}{2} + 2 \sum_{i>j} \Im(U_{\alpha i}^* U_{\beta i} U_{\alpha j} U_{\beta j}^*) \sin \Delta_{ij},$$

(2)

where $m_j$ is the mass of $\nu_i$ and $\Delta_{ij}$ is

$$\Delta_{ij} \equiv \frac{m_j^2 - m_i^2}{2E} L \simeq 2.534 \frac{(m_j^2 - m_i^2) [\text{eV}^2]}{E [\text{GeV}]} L [\text{km}].$$

Equation (2) shows that neutrino flavor oscillation is governed by the two mass-squared differences and the lepton number conserving combinations of the MNS matrix elements.

We take $|\Delta_{13}| > |\Delta_{12}|$ without losing generality. Under this parameterization, atmospheric neutrino observation [2] and the accelerator based long baseline (LBL) experiments, K2K [3] and MINOS [4], which measure the $\nu_\mu$ survival probability, are sensitive to the magnitude of the larger mass-squared difference and $U_{\mu3}$:

$$1.5 \times 10^{-3} \text{eV}^2 < |m_3^2 - m_1^2| < 3.4 \times 10^{-3} \text{eV}^2,$$

$$\sin^2 2\theta_{\text{ATM}} \equiv 4U_{\mu2}^2 (1 - U_{\mu3}^2) > 0.92,$$

(4a)  (4b)
each at the 90% confidence level. Hereafter, we use $\sin^2 \theta_{\text{ATM}}$ instead of the $U_{\mu 3}^2$ for brevity.

The reactor experiments, which observe the survival probability of the $\bar{\nu}_e$ at $L \sim 1\,\text{km}$ from a reactor, are sensitive to the value of the larger mass-squared difference and the absolute value of $U_{e3}$. The CHOOZ experiment [5] reported no reduction of the $\bar{\nu}_e$ flux and find

$$\sin^2 2\theta_{\text{RCT}} \equiv 4 |U_{e3}|^2 (1 - |U_{e3}|^2) < (0.20, 0.16, 0.14)$$

for $|m_3^2 - m_1^2| = (2.0, 2.5, 3.0) \times 10^{-3}\,\text{eV}^2$, (5)

at the 90% confidence level. In the following, we denote $|U_{e3}|^2$ as $\sin^2 \theta_{\text{RCT}}$.

The solar neutrino observations [6], and the KamLAND experiment [7], which measure the survival probability of $\nu_e$ and $\bar{\nu}_e$, respectively, are sensitive to the smaller mass-squared difference and the value of $U_{e2}$. The present constraints can be expressed as

$$m_2^2 - m_1^2 = (8.0 \pm 0.3) \times 10^{-5}\,\text{eV}^2,$$

$$\sin^2 \theta_{\text{SOL}} = 0.30 \pm 0.03.$$ (6b)

The sign of $m_2^2 - m_1^2$ is determined by the matter effect in the sun [19, 20]. In these experiments, the order of $\Delta_{12}$ is roughly 1 and the terms with $\Delta_{13}$ oscillate quickly within the experimental resolution of $L/E$. After averaging out the contribution from $\Delta_{13}$, and neglecting terms of order $\sin^2 \theta_{\text{RCT}}$, we obtain the relation;

$$\sin^2 2\theta_{\text{SOL}} = 4U_{e1}^2 U_{e2}^2 = 4U_{e2}^2 (1 - U_{e2}^2 - |U_{e3}|^2).$$ (7)

These simple identification, eqs.(4b), (5), and (7), are found to give a reasonably good description of the present data in dedicated studies [21] of the experimental constraints in the three neutrino model. In this paper, we parameterize the CP phase as [18]

$$\delta_{\text{MNS}} = - \arg U_{e3}.$$ (8)

The other elements of the MNS matrix can be obtained from the unitary conditions [17]. This convention allows us to express the MNS matrix directly in terms of the three observed amplitudes.

The probability of the neutrino oscillation, eq.(2), is modified by the matter effect [19, 20], because only $\nu_e$ and $\bar{\nu}_e$ feel the potential by the extra charged current interactions with the electron inside the matter. This extra potential for $\nu_e$ is written as

$$a = 2\sqrt{2}G_F E_{\nu} n_e \simeq 7.56 \times 10^{-5}[\text{eV}^2] \left( \frac{\rho}{\text{g/cm}^3} \right) \left( \frac{E_{\nu}}{\text{GeV}} \right),$$ (9)

where $G_F$ is the Fermi coupling constant, $E_{\nu}$ is the neutrino energy, $n_e$ is the electron number density, and $\rho$ is the matter density. The extra potential for $\bar{\nu}_e$ has the opposite sign. Because the matter effect is small at low energies and also because the phase factor $\Delta_{12}$ is small near
the first oscillation maximum, $\Delta_{13} \sim \pi$, we find that an approximation of keeping terms linear in the matter effect and $\Delta_{12}$ is useful for analyzing the LBL experiments at sub GeV to a few GeV region \[8, 9, 22, 23\]:

$$P_{\nu_\mu \to \nu_e} = 2(1 + q) \sin^2 \theta_{\text{RCT}} (1 + A^e) \sin^2 \left( \frac{\Delta_{13}}{2} + B^e \right),$$  \hspace{2cm} (10a)$$

$$P_{\nu_\mu \to \nu_\mu} = 1 - (1 - q^2) (1 + A^\mu) \sin^2 \left( \frac{\Delta_{13}}{2} + B^\mu \right),$$  \hspace{2cm} (10b)$$

where

$$\sin^2 \theta_{\text{ATM}} = \frac{1 + q}{2},$$  \hspace{2cm} (11)$$

and $A^\alpha$ and $B^\alpha$ are the correction terms to the amplitude and the oscillation phase, respectively.

For $\alpha = e$, we find

$$A^e = \frac{aL}{\Delta_{13}E} \cos 2\theta_{\text{RCT}} - \frac{\Delta_{12} \sin 2\theta_{\text{SOL}}}{2} \sin \theta_{\text{RCT}} \sqrt{\frac{1 - q}{1 + q}} \sin \delta_{\text{MNS}},$$  \hspace{2cm} (12a)$$

$$B^e = -\frac{aL}{4E} \cos 2\theta_{\text{RCT}} + \frac{\Delta_{12}}{2} \left( \frac{\sin 2\theta_{\text{SOL}}}{2 \sin \theta_{\text{RCT}}} \sqrt{\frac{1 - q}{1 + q}} \cos \delta_{\text{MNS}} - \sin^2 \theta_{\text{SOL}} \right).$$  \hspace{2cm} (12b)$$

The octant degeneracy between $\theta_{\text{ATM}}$ and $90^\circ - \theta_{\text{ATM}}$ corresponds to the degeneracy in the sign of $q$. When $q$ denotes the true value for the octant degeneracy, $-q$ is its fake value.

Using typical numbers of the parameters from the atmospheric neutrino observation and LBL experiments, eq.(4), and those from the solar neutrino observation and the KamLAND experiment, eq.(6), the $\nu_\mu \to \nu_e$ transition probability can be expressed as

$$P_{\nu_\mu \to \nu_e} \sim 0.05 (1 + q) \left( \frac{\sin^2 2\theta_{\text{RCT}}}{0.10} \right) (1 + A^e) \sin^2 \left( \frac{\Delta_{13}}{2} + B^e \right).$$  \hspace{2cm} (13a)$$

$$A^e \sim 0.37 \left( \frac{\pi}{\Delta_{13}} \right) \left( \frac{L}{1000[\text{km}]} \right) - 0.29 \sqrt{\frac{1 - q}{1 + q}} \left( \frac{0.10}{\sin^2 2\theta_{\text{RCT}}} \right)^{1/2} \sin \delta_{\text{MNS}} \frac{\Delta_{13}}{\pi},$$  \hspace{2cm} (13b)$$

$$B^e \sim -0.29 \left( \frac{L}{1000[\text{km}]} \right) + 0.15 \sqrt{\frac{1 - q}{1 + q}} \left( \frac{0.10}{\sin^2 2\theta_{\text{RCT}}} \right)^{1/2} \cos \delta_{\text{MNS}} - 0.015 \frac{\Delta_{13}}{\pi},$$  \hspace{2cm} (13c)$$

around the oscillation maximum, $|\Delta_{13}| \sim \pi$. Since the amplitude is proportional to $\sin^2 \theta_{\text{ATM}} = (1 + q)/2$, we expect that the octant degeneracy can be solved by measuring the $\nu_\mu \to \nu_e$ transition probability, if the value of the $\sin^2 2\theta_{\text{RCT}}$ is known precisely. Because the first term of $A^e$ changes sign according to the mass hierarchy pattern, $\Delta_{13} \sim \pi$ for the normal and $\Delta_{13} \sim -\pi$ for the inverted, the amplitude of the transition probability is sensitive to the mass hierarchy pattern. The difference between the two hierarchy cases grows with the baseline length when $L/E$ is fixed at around the oscillation maximum \[8, 9\]. If there is only one detector at
$L \sim O(100)$ km, the small difference from the matter effect can be absorbed by the sign of $q$ in the leading term of eq. (13a).

The $q$-dependence in $A^e$ and $B^e$ in eqs. (13b) and (13c) may seem to affect the measurement of the leptonic CP phase. We find, however, that the $q$-dependence of the coefficient of the CP phase in the $\nu_\mu \rightarrow \nu_e$ transition probability is not strong, because

$$(1 + q) \sqrt{\frac{1 - q}{1 + q}} = \sqrt{1 - q^2},$$

which is independent of the octant degeneracy. Our numerical studies presented below confirms the validity of the above approximations.

Around the first dip of the $\nu_\mu$ survival probability $|\Delta_{13}| \sim \pi$, we find

$$A^\mu \sim 0.018 \left( \frac{q}{1 - q} \right) \left( \frac{\pi}{\Delta_{13}} \right) \left( \frac{L}{1000\text{[km]}} \right) \left( \frac{\sin^2 2\theta_{\text{RCT}}}{0.10} \right),$$

$$B^\mu \sim 0.014 \left( \frac{q}{1 - q} \right) \left( \frac{L}{1000\text{[km]}} \right) \left( \frac{\sin^2 2\theta_{\text{RCT}}}{0.10} \right)$$

$$- \left[ 0.037 - 0.008 \left( \frac{\sin^2 2\theta_{\text{RCT}}}{0.10} \right) \cos \delta_{\text{MNS}} \right] \frac{|\Delta_{13}|}{\pi}.$$  

(15b)

Although the shift in the amplitude $A^e$ and that in the phase $B^\mu$ are both proportional to $q$, their magnitudes are found to be less than 0.7% and 0.5%, respectively, for $|q| < 0.28$, eq. (4b). Our numerical results confirm that the measurement of the $\nu_\mu \rightarrow \nu_\mu$ survival probability does not contribute significantly to the resolution of the octant degeneracy. On the other hand the smallness of the deviation from the leading contribution allows us to constrain $|m_3^2 - m_1^2|$ and $\sin^2 2\theta_{\text{ATM}}$ accurately by measuring the $\nu_\mu \rightarrow \nu_\mu$ survival probability.

### 3 Analysis method

In this section, we explain how we treat signals and backgrounds in our numerical analysis, and introduce a $\chi^2$ function which measures the capability of the T2KK experiment semi-quantitatively. We consider a water Čerenkov detector at Korea in this study, because it allows us to distinguish clearly the $e^\pm$ events from $\mu^\pm$ events. The fiducial volume of the detector placed at Korea is assumed 100 kton, which is roughly 5 times larger than that of SK, 22.5 kton, in order to compensate for the longer base-line length. We use only the CCQE events in our analysis, because they allow us to reconstruct the neutrino energy event by event [3]. Since the Fermi-motion of the target nucleon would dominate the uncertainty of the neutrino energy reconstruction, which is about 80 MeV [3], we take the width of the energy bin as
δE_{ν} = 200 \text{ MeV} \text{ for } E_ν > 400 \text{ MeV}. \text{ The signals in the } i \text{-th energy bin, } E_ν^i \equiv (200 \text{MeV} \times i) < E_ν < E_ν^i + δE_ν, \text{ are then calculated as}

\[ N_i^α(ν_μ) = M N_A \int_{E_ν^i}^{E_ν^i+δE_ν} \Phi_{ν_μ}(E) P_{ν_μ→ν_α}(E) σ^{QE}_α(E) \, dE, \] (16)

where \( P_{ν_μ→ν_α} \) is the neutrino oscillation probability including the matter effect, \( M \) is the detector mass, \( N_A = 6.017 \times 10^{23} \) is the Avogadro constant, \( \Phi_{ν_μ} \) is the \( ν_μ \) flux from J-PARC [24], and \( σ^{QE}_α \) is the CCQE cross section per nucleon in water [3]. For simplicity, the detection efficiencies of both detectors for both \( ν_μ \) and \( ν_e \) CCQE events are set at 100%.

We consider the following background events for the signal of e-like events (\( α = e \)) and µ-like events (\( α = µ \)),

\[ N_i^{BG}_α = N_i^α(ν_e) + N_i^α(ν_μ) + N_i^α(\bar{ν}_e), \quad (α = e, µ), \] (17)

respectively. The three terms correspond to the contribution from the secondary neutrino flux of the \( ν_μ \) primary beam, which are calculated as in eq.(16) where \( Φ_{ν_μ}(E) \) is replaced by \( Φ_{ν_β}(E) \) for \( ν_β = ν_e, \bar{ν}_e, \bar{ν}_μ \). All the primary as well as secondary fluxes used in our analysis are obtained from the web-site [24]. After summing up these background events, the e-like and µ-like events for the \( i \)-th bin are obtained as

\[ N_i^α = N_i^α(ν_μ) + N_i^{BG}_α, \quad (α = e, µ), \] (18)

respectively.

Our interest is the potential of the T2KK experiment for solving the octant degeneracy and its influence on the resolution of the other degeneracies. In order to quantify its capability, we introduce a \( χ^2 \) function,

\[ Δχ^2 \equiv χ^2_{SK} + χ^2_{Kr} + χ^2_{sys} + χ^2_{para}, \] (19)

which measures the sensitivity of the experiment on the model parameters. The first two terms, \( χ^2_{SK} \) and \( χ^2_{Kr} \), measure the parameter dependence of the fit to the SK and the Korean detector data, respectively,

\[ χ^2_{SK,Kr} = \sum_i \left\{ \left( \frac{(N_i^ε)^{\text{fit}} - (N_i^ε)^{\text{input}}}{\sqrt{(N_i^ε)^{\text{input}}}} \right)^2 + \left( \frac{(N_i^μ)^{\text{fit}} - (N_i^μ)^{\text{input}}}{\sqrt{(N_i^μ)^{\text{input}}}} \right)^2 \right\}, \] (20)

where \( N_{μ,e}^i \) is the calculated number of events in the \( i \)-th bin, and its square root gives the statistical error. Here the summation is over all bins from 0.4 GeV to 5.0 GeV for \( N_μ \), 0.4 GeV to 1.2 GeV for \( N_e \) at SK, and 0.4 GeV to 2.8 GeV for \( N_e \) at Korea. In this energy region, we can include the second peak contribution in our analysis at Korea. In this energy region, we can include the second peak contribution in our analysis at Korea. We include the contribution of the \( μ \)-like events in order to constrain the absolute value of \( Δ_{13} \) strongly in this analysis, because a small error of \( Δ_{13} \) dilutes the phase shift \( B^e \) [8, 9, 22].
$N_{i}^{\text{fit}}$ is calculated by allowing the model parameters to vary freely and by including the systematic errors. We take into account four types of the systematic errors in this analysis. The first systematic error is for the uncertainty in the matter density, for which we allow 3% overall uncertainty along the baseline, independently for T2K ($f_{\rho}^{SK}$) and the Tokai-to-Korea experiment ($f_{\rho}^{Kr}$):

$$\rho_{i}^{\text{fit}} = f_{\rho}^{D} \rho_{i}^{\text{input}} \quad (D = SK, Kr).$$ (21)

The second ones are for the overall normalization of each neutrino flux, for which we assume 3% errors,

$$f_{\nu_{\beta}} = 1 \pm 0.03,$$ (22)

for ($\nu_{\beta} = \nu_{e}, \bar{\nu}_{e}, \nu_{\mu}, \bar{\nu}_{\mu}$), which are taken common for T2K and the Tokai-to-Korea experiment. The third ones are for the CCQE cross sections,

$$\left(\sigma_{\text{QE}}^{\alpha}\right)^{\text{fit}} = f_{\alpha}^{\text{QE}} \left(\sigma_{\text{QE}}^{\alpha}\right)^{\text{input}},$$ (23)

where $\alpha$ denotes $\ell \equiv e = \mu$ and $\bar{\ell} \equiv \bar{e} = \bar{\mu}$. Because $\nu_{e}$ and $\nu_{\mu}$ CCQE cross sections are expected to be very similar theoretically, we assign a common overall error of 3% for $\nu_{e}$ and $\nu_{\mu}$ and an independent 3% error for $\bar{\nu}_{e}$ and $\bar{\nu}_{\mu}$ CCQE cross sections. The last one is the uncertainty of the fiducial volume, for which we assign 3% error independently for T2K ($f_{V}^{SK}$) and the Tokai-to-Korea experiment ($f_{V}^{Kr}$). $N_{i}^{\text{fit}}$ is then calculated as

$$\left[N_{i}^{\text{fit}}(\nu_{\beta})\right]_{\text{at SK,Kr}} = f_{\nu_{\beta}} f_{\alpha}^{\text{QE}} f_{V}^{SK,Kr} N_{i}^{\text{fit}}(\nu_{\beta}),$$ (24)

and accordingly, $\chi_{\text{sys}}^{2}$ has four terms;

$$\chi_{\text{sys}}^{2} = \sum_{\beta=e,\bar{e},\mu,\bar{\mu}} \left(\frac{f_{\nu_{\beta}} - 1}{0.03}\right)^{2} + \sum_{\alpha=\ell,\bar{\ell}} \left(\frac{f_{\alpha}^{\text{CCQE}} - 1}{0.03}\right)^{2} + \sum_{D=SK, Kr} \left\{\left(\frac{f_{\rho}^{D} - 1}{0.03}\right)^{2} + \left(\frac{f_{V}^{D} - 1}{0.03}\right)^{2}\right\}. \quad (25)$$

To put them shortly, we account for 4 types of uncertainties which are all assigned 3% errors: the effective matter density along each baseline, the normalization of each neutrino flux, the CCQE cross sections for $\nu_{l}$ and $\bar{\nu}_{l}$, and for the fiducial volume of SK, and that of the Korean detector. In total, our $\Delta\chi^{2}$ function depends on 16 parameters, the 6 model parameters and the 10 normalization factors.

Finally, $\chi_{\text{para}}^{2}$ accounts for external constraints on the model parameters:

$$\chi_{\text{para}}^{2} = \left(\frac{m_{2} - m_{1}^{\text{fit}}}{0.6 \times 10^{-5}\text{eV}^{2}} - 8.2 \times 10^{-5}\text{eV}^{2}\right)^{2} + \left(\frac{\sin^{2} 2\theta^{\text{fit}}_{\text{sol}} - 0.83}{0.07}\right)^{2}$$

$$+ \left(\frac{\sin^{2} 2\theta^{\text{fit}}_{\text{RCT}} - \sin^{2} 2\theta^{\text{input}}_{\text{RCT}}}{0.01}\right)^{2}. \quad (26)$$
The first two terms correspond to the present experimental constraints from solar neutrino oscillation and KamLAND summarized in eq.(6) *. In the last term, we assume that the planned future reactor experiments [25] should measure $\sin^2 2\theta_{\text{RCT}}$ with the expected uncertainty of 0.01.

4 Octant degeneracy and the T2KK experiment

In this section, we show the potential of the T2KK experiment for solving the octant degeneracy and investigate the role of the far detector and the future reactor experiments. We show in Fig.1 the minimum $\Delta \chi^2$ and investigate the role of the far detector and the future reactor experiments. We show in Fig.1 the minimum $\Delta \chi^2$ as a function of $\sin^2 \theta_{\text{ATM}}$ expected at the T2KK experiment after 5 years of data taking ($5 \times 10^{21}$ POT). The event numbers are calculated for a combination of $3.0^\circ$ OAB at SK and $0.5^\circ$ OAB at $L = 1000\text{km}$ for the following parameters:

\begin{align}
(m_3^2 - m_1^2)^{\text{input}} &= 2.5 \times 10^{-3}\text{eV}^2 \text{ (normal hierarchy)}, \quad (27a) \\
(m_2^2 - m_1^2)^{\text{input}} &= 8.2 \times 10^{-5}\text{eV}^2, \quad (27b) \\
\sin^2 2\theta_{\text{RCT}}^{\text{input}} &= 0.10, \quad (27c) \\
\sin^2 2\theta_{\text{SOL}}^{\text{input}} &= 0.83, \quad (27d) \\
\delta_{\text{MNS}}^{\text{input}} &= 0^\circ, \pm 90^\circ, 180^\circ, \quad (27e) \\
\rho_{\text{input}} &= 3.0\text{g/cm}^3 \text{ for } L = 1000\text{km}, \quad (27f) \\
\rho_{\text{input}} &= 2.8\text{g/cm}^3 \text{ for } \text{SK.} \quad (27g)
\end{align}

In the left-hand figure of Fig.1, we show the cases for the input values $\sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.35$ (a), $0.40$ (b), $0.45$ (c) and in the right-hand figure, for $\sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.55$ (d), $0.60$ (e), $0.65$ (f). In each cases, the fit has been performed by surveying the whole parameter space. We find from Fig.1, that the octant degeneracy can be solved by T2KK experiment when $\sin^2 2\theta_{\text{ATM}} = 0.91$ i.e., between $\sin^2 \theta_{\text{ATM}} = 0.35$ and 0.65 at $4\sigma$. For $\sin^2 2\theta_{\text{ATM}} = 0.96$ the degeneracy between $\sin^2 \theta_{\text{ATM}} = 0.40$ and 0.60 can be resolved with $\Delta \chi^2 \geq 7$, or at $2.6\sigma$. However, it is difficult to solve the octant degeneracy for $\sin^2 2\theta_{\text{ATM}} = 0.99$, between $\sin^2 \theta_{\text{ATM}} = 0.45$ and 0.55.

In the left-hand figure of Fig.1, the minimum $\Delta \chi^2$ for $\delta = 90^\circ$ is larger than those for the other CP phases. In the right-hand figure, the minimum $\Delta \chi^2$ is also largest at $\delta = 90^\circ$. There, however, the minimum $\Delta \chi^2$ for $\delta = -90^\circ$ is slightly larger than those for $\delta = 0^\circ, 180^\circ$.

In order to explore the $\delta_{\text{MNS}}$ dependence of the capability of the T2KK experiment to solve the octant degeneracy, we show in Fig.2 contours of the minimum $\Delta \chi^2$ in the whole space of $\sin^2 2\theta_{\text{RCT}}^{\text{input}}$ and $\delta_{\text{MNS}}^{\text{input}}$. The event numbers are calculated for various $\sin^2 2\theta_{\text{ATM}}^{\text{input}}$ and $\delta_{\text{MNS}}^{\text{input}}$ values in each figure, with $\sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.40$ for (a) and (c), or $\sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.60$ for (b) and (d). The other model parameters are set as in eq.(27). Figs.2 (a) and (b) are for the normal hierarchy, $m_3^2 - m_1^2 = 2.5 \times 10^{-3}\text{eV}^2$, and Figs.2 (c) and (d) are for the inverted hierarchy, $m_3^2 - m_1^2 = -2.5 \times 10^{-3}\text{eV}^2$. In performing the fit, all the 16 parameters (6 model parameters and 10 normalization factors) are varied freely under the following constraints: $\sin^2 \theta_{\text{ATM}}^{\text{fit}} > 0.5$

*The most recent results, eq.(6), are slightly different from our inputs. Because our analysis is not sensitive to the difference, we use these values for the sake of keeping the consistency with our previous studies [8, 9].
Figure 1: Minimum $\Delta \chi^2$ of the T2KK experiment as a function of $\sin^2 \theta_{\text{ATM}}$. The event numbers are calculated for a combination of 3.0° OAB at SK and 0.5° OAB at $L = 1000$km with 100 kton water Čerenkov detector, after 5 years running ($5 \times 10^{21}$ POT). The input parameters are chosen as in eq.(27). In the left-hand figure, $\sin^2 \theta_{\text{ATM}}^\text{input} = 0.35$ (a), 0.40 (b), 0.45 (c) and in the right-hand figure, $\sin^2 \theta_{\text{ATM}}^\text{input} = 0.55$ (d), 0.60 (e), 0.65 (f).

for (a) and (c), $\sin^2 \theta_{\text{ATM}}^\text{fit} < 0.5$ for (b) and (d), $(m_3^2 - m_1^2)^\text{fit} > 0$ for (a) and (b), $(m_3^2 - m_1^2)^\text{fit} < 0$ for (c) and (d). From Figs.2(a) and 2(c), we find that $\sin^2 \theta_{\text{ATM}}^\text{input} = 0.40$ can be distinguished from $\sin^2 \theta_{\text{ATM}}^\text{fit} > 0.5$ at $\Delta \chi^2 > 9$ (4) for $\sin^2 2\theta_{\text{R}^\text{CT}}^\text{input} \gtrsim 0.12$ (0.09) when the normal (inverted) hierarchy is realized. Figs.2(b) and 2(d) show that the octant degeneracy can be solved at $\Delta \chi^2 > 9$ for $\sin^2 2\theta_{\text{R}^\text{CT}}^\text{input} \gtrsim 0.12$ (0.14) when $\sin^2 \theta_{\text{ATM}}^\text{input} = 0.60$ for the normal (inverted) hierarchy.

It is found in Figs.2(a) and 2(b) that the minimum $\Delta \chi^2$ is highest around $\delta_{\text{MNS}}^\text{input} = 90^\circ$, confirming the trend observed in Fig.1. We find from Figs.2(c) and 2(d) that the same trend holds even when the neutrino mass hierarchy is inverted. In all the four plots of Fig.2, we recognize a high plateau around $\delta_{\text{MNS}}^\text{input} = 90^\circ$ and a lower plateau around $\delta_{\text{MNS}}^\text{input} = -90^\circ$. We can understand the trend by using the approximate expression of the $\nu_\mu \to \nu_e$ transition probability, eq.(13). We first note that the $\nu_\mu \to \nu_e$ oscillation probability is proportional to $(1 + q)(1 + A^e)\sin^2 2\theta_{\text{R}^\text{CT}}$ around the oscillation maxima, $|\Delta_{13} = (2n + 1)\pi|$. When $q = -0.2$, the $\nu_e$ appearance rate is proportional to $0.8(1 + A^e)$. In order to reproduce the same rate for $q = 0.2$, we should find a parameter set that makes the factor $1 + A^e$ 40% smaller than its input value, up to the uncertainty in $\sin^2 2\theta_{\text{R}^\text{CT}}$, which is assumed to be $0.01/\sin^2 2\theta_{\text{R}^\text{CT}}$ in eq.(26). This cannot be achieved for $\delta_{\text{MNS}}^\text{input} = 90^\circ$, because the input value of $1 + A^e$ takes its minimum value. On the other hand, if $\delta_{\text{MNS}}^\text{input} = -90^\circ$ the input value of $1 + A^e$ is large and it can be reduced significantly by choosing $\delta_{\text{MNS}}^\text{fit} = 90^\circ$ in the fit. This explains why the minimum $\Delta \chi^2$ is larger around $\delta_{\text{MNS}}^\text{input} = 90^\circ$ than that around $\delta_{\text{MNS}}^\text{input} = -90^\circ$ when $\sin^2 \theta_{\text{ATM}} = 0.4$ in Figs.2(a) and 2(c). When $q = 0.2$, the same argument tells that we cannot compensate for the large input value of $(1 + q)(1 + A^e)$ for $\delta_{\text{MNS}}^\text{input} = -90^\circ$. This indeed explains the lower plateau around $\delta_{\text{MNS}}^\text{input} = -90^\circ$ observed in 2(b) and 2(d). The cause of the higher plateau around $\delta_{\text{MNS}}^\text{input} = 90^\circ$ in these figures for $\sin^2 \theta_{\text{ATM}} = 0.6$ is more subtle. When $\delta_{\text{MNS}}^\text{input} = 90^\circ$, $(1 + A^e)^\text{input}$ takes its smallest value, and the reduction in $(1 + q)$ from $(1 + q)^\text{input} = 1 + 0.2$ to $(1 + q)^\text{fit} = 1 - 0.2$ can be compensated for by making $(1 + A^e)^\text{fit}$ larger by choosing $\delta_{\text{MNS}}^\text{fit} \simeq -90^\circ$. This, however,
necessarily makes the coefficient of $|\Delta_{13}|/\pi$ in eq. (13b) have the wrong sign, and hence the ratio of the first peak ($|\Delta_{13}| \sim \pi$) and the second peak ($|\Delta_{13}| \sim 3\pi$) cannot be reproduced. The higher plateau around $\delta_{\text{MNS}}^{\text{input}} = 90^\circ$ in Figs.2(b) and 2(d) for $\sin^2\theta_{\text{ATM}}^{\text{input}} = 0.6$, and the lower plateau around $\delta_{\text{MNS}}^{\text{input}} = -90^\circ$ in Figs.2(a) and 2(c) for $\sin^2\theta_{\text{ATM}}^{\text{input}} = 0.4$ can be explained as above.

We show in Fig.3 the allowed region of $\sin^2\theta_{\text{ATM}}$ and $\sin^22\theta_{\text{RCT}}$ by the T2KK experiment. The event numbers are generated at $\delta_{\text{MNS}}^{\text{input}} = 0^\circ$ and $\sin^22\theta_{\text{RCT}}^{\text{input}} = 0.10$ for $\sin^2\theta_{\text{ATM}}^{\text{input}} = 0.35$, 0.40, 0.45, 0.50, 0.55, 0.60, 0.65 from the 1st to the 7th row. The other input parameters are the same as in eq. (27). The allowed regions in the plane of $\sin^2\theta_{\text{ATM}}$ and $\sin^22\theta_{\text{RCT}}$ are shown by the $\Delta\chi^2 = 1$, 4, 9 contours depicted as solid, dashed, and dotted lines, respectively. In the left-hand-side plots, (a), the constraint on $\sin^22\theta_{\text{RCT}}$ from the future reactor experiment is kept in the $\Delta\chi^2$ function. On the other hand, in the right-hand-side plots, (b), the external constraint on $\sin^22\theta_{\text{RCT}}$ is removed from the $\Delta\chi^2$ function in eq. (26). Comparing Figs.3(a) and
Figure 3: The capability of the T2KK experiment for constraining the $\sin^2 \theta_{\text{ATM}}$ and $\sin^2 2\theta_{\text{RCT}}$. Allowed regions in the plane of $\sin^2 \theta_{\text{ATM}}$ and $\sin^2 2\theta_{\text{RCT}}$ are shown for the same T2KK set up Fig.1. In each figure, the event numbers are generated at $\delta_{\text{MNS}}^{\text{input}} = 0^\circ$ and $\sin^2 2\theta_{\text{RCT}}^{\text{input}} = 0.10$, for $\sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.35, 0.40, 0.45, 0.50, 0.55, 0.60, 0.65$ from the 1st to the 7th row. The other input parameters are the same as in Fig.1. In the left-hand-side plots, (a), we keep the constraint on $\sin^2 2\theta_{\text{RCT}}$ form the future reactor experiment, whereas in the right-hand-side plots, (b), we remove the external constraint on $\sin^2 2\theta_{\text{RCT}}$ in eq.(26). The $\Delta \chi^2 = 1, 4, 9$ contours are shown by the solid, dashed, and dotted lines, respectively.
Figure 4: The same as Fig.2, but with 5 times larger exposure ($25 	imes 10^{21}$ POT).

For $\sin^2 2\theta_{\text{ATM}} = 0.4$ and $\sin^2 2\theta_{\text{ATM}} > 0.5$ (normal), we find that the mirror solution around

$$\sin^2 2\theta_{\text{fit}} = \frac{1 + q}{1 - q} \sin^2 2\theta_{\text{input}}$$

(28)

cannot be excluded without the information from the future reactor experiment.

Before closing the section, we examine the impact of upgrading the J-PARC beam intensity be a factor of 5 [26] on the resolution of the octant degeneracy. Such an upgrade is desirable especially if the neutrino mass hierarchy is inverted, because the octant degeneracy between $\sin^2 \theta_{\text{ATM}} = 0.4$ and 0.6 cannot be resolved at 3$\sigma$ unless $\delta_{\text{MNS}} \approx 90^\circ$; see Figs.2(c) and 2(d).

We show in Fig.4 the same contour plots as in Fig.2, but with 5 times larger exposure ($25 \times 10^{21}$ POT). It is found that the degeneracy between $\sin^2 \theta_{\text{ATM}} = 0.4$ and 0.6 can now be resolved at 3$\sigma$ level for $\sin^2 2\theta_{\text{RCT}} > 0.08$ (0.09), when the hierarchy is normal (inverted). Comparing Fig.2 and Fig.4, however, we find that the sensitivity does not improve as much as we would hope with 5 times higher statistics. The minimum $\Delta \chi^2$ value does not grow by a factor 5, because the capability of resolving the octant degeneracy is now dictated by the accuracy of the external constraint on $\sin^2 2\theta_{\text{RCT}}$ from the future reactor experiment,

$$\frac{\delta \sin^2 2\theta_{\text{RCT}}}{\sin^2 2\theta_{\text{RCT}}} = \frac{0.01}{\sin^2 2\theta_{\text{RCT}}}$$

(29)

which we assume in eq.(26). The fractional uncertainty of $\sin^2 2\theta_{\text{RCT}}$ is 10% for $\sin^2 2\theta_{\text{RCT}} = 0.1$,
Figure 5: Minimum $\Delta \chi^2$ as a function of $\sin^2 \theta_{\text{ATM}}$ for the same T2KK setting as in Fig.1. In each figure, the event numbers are calculated for the parameters of eq. (27) with $\delta_{\text{input}} = 0^\circ$ (a), $90^\circ$ (b), $180^\circ$ (c), $-90^\circ$ (d), under the normal hierarchy, and the fit has been performed by assuming the inverted hierarchy. The solid line gives the minimum $\Delta \chi^2$. The open circle (square) denotes the minimum value of $\Delta \chi^2$ when the sign of $q_{\text{input}} q_{\text{fit}}$, or that of $(1 - 2 \sin^2 \theta_{\text{ATM}}) (1 - 2 \sin^2 \theta_{\text{ATM}})$, is positive, whereas the open square gives

but it is 17% for $\sin^2 2\theta_{\text{RCT}} = 0.06$. If $\sin^2 2\theta_{\text{RCT}}$ turns out to be even smaller, the fractional error grows and the mirror solution eq.(28) can no more be resolved. If $\sin^2 2\theta_{\text{RCT}}$ turns out to be smaller than 0.06, further reduction of its error in the future experiments with reactor and/or the beta beam [27].

5 Mass hierarchy and the octant degeneracy

In this section, we examine the effect of the octant degeneracy on the capability of the T2KK experiment to determine the neutrino mass hierarchy pattern.

Figure 5 shows the minimum $\Delta \chi^2$ as a function of $\sin^2 \theta_{\text{ATM}}$ for the T2KK experiment to determine the mass hierarchy pattern with the same OAB combination of Fig.1. In each figure, the event numbers are calculated for $\delta_{\text{input}} = 0^\circ$ (a), $90^\circ$ (b), $180^\circ$ (c), and $-90^\circ$ (d), when the normal hierarchy is realized. The other parameters are listed in eq.(27). The fit has been performed by surveying the whole parameter space by assuming the wrong hierarchy. The solid line gives the minimum $\Delta \chi^2$. The open circle denotes the minimum value of $\Delta \chi^2$ when the sign of $q_{\text{input}} q_{\text{fit}}$, or that of $(1 - 2 \sin^2 \theta_{\text{ATM}}) (1 - 2 \sin^2 \theta_{\text{ATM}})$, is positive, whereas the open square gives
the minimum $\Delta \chi^2$ when $q^{\text{input}} q^{\text{fit}}$ is negative.

When $q^{\text{fit}}$ takes the same sign as $q^{\text{input}}$, $\sin^2 \theta_{\text{ATM}}^{\text{fit}} \sim \sin^2 \theta_{\text{ATM}}^{\text{input}}$ is favored, and the reduction of the $\nu_\mu \rightarrow \nu_e$ oscillation amplitude $(1 + A^e)$ in eq.(13b) for the inverted hierarchy, $\Delta_{13} \sim -\pi$, cannot be compensated for in the two detector experiment [8, 9]. Because the $\nu_\mu \rightarrow \nu_e$ rate is proportional to $\sin^2 \theta_{\text{ATM}}^{\text{input}}$, the resulting increase in the discrepancy leads to the linear dependence of the minimum $\Delta \chi^2$ on $\sin^2 \theta_{\text{ATM}}^{\text{fit}}$ observed for the open circle points. On the other hand, when $\sin^2 \theta_{\text{ATM}}^{\text{input}} < 0.5$ ($q^{\text{input}} < 0$), it is possible to compensate for the reduction of the $1 + A^e$ factor of the $\nu_\mu \rightarrow \nu_e$ oscillation amplitude by choosing $q^{\text{fit}} \sim -q^{\text{input}}$, since $\sin^2 \theta_{\text{ATM}}^{\text{fit}} = \sin^2 \theta_{\text{ATM}}^{\text{input}}(1 + q^{\text{fit}})/(1 + q^{\text{input}}) > 0.5$. This explains why the open square points for $q^{\text{input}} q^{\text{fit}} < 0$ gives the lowest $\Delta \chi^2$ for $\sin^2 \theta_{\text{ATM}}^{\text{fit}} < 0.5$. When $\sin^2 \theta_{\text{ATM}}^{\text{input}}$ is significantly lower than 0.5, however, the enlargement factor of $\sin^2 \theta_{\text{ATM}}^{\text{fit}}/ \sin^2 \theta_{\text{ATM}}^{\text{input}} = (1 + q^{\text{fit}})/(1 + q^{\text{input}})$ overshoots the reduction due to the matter effect, especially for the $\nu_\mu \rightarrow \nu_e$ rate at SK when the matter effect is small. When $\delta_{\text{MNS}}^{\text{input}} = -90^\circ$, shown in Fig.5(d), this reduction in the minimum $\Delta \chi^2$ by using the octant degeneracy is most significant because the overshooting of the $\nu_\mu \rightarrow \nu_e$ rate can be partially compensated by choosing $\sin^2 \delta_{\text{MNS}}^{\text{fit}} > 0$.

In Fig.6, we show the minimum $\Delta \chi^2$ as a function of $\sin^2 \theta_{\text{ATM}}^{\text{input}}$ when the neutrino mass hierarchy is inverted. The gradual increase of the $\Delta \chi^2$ as $\sin^2 \theta_{\text{ATM}}^{\text{input}}$ grows can also be seen for the open circle points where the fit is restricted to the parameter space that satisfies $q^{\text{fit}} q^{\text{input}} > 0$. This reflects the increase of the $\nu_\mu \rightarrow \nu_e$ event rate as $\sin^2 \theta_{\text{ATM}}^{\text{input}}$ increases, independent of the hierarchy pattern. On the other hand, the minimum $\Delta \chi^2$ for the parameter space of $q^{\text{fit}} q^{\text{input}} < 0$, plotted by open squares, gives the lowest $\Delta \chi^2$ when $\sin^2 \theta_{\text{ATM}}^{\text{fit}} > 0.5$. This is because the reduction of the $\nu_\mu \rightarrow \nu_e$ rate in the fit, which is proportional to $\sin^2 \theta_{\text{ATM}}^{\text{fit}}/ \sin^2 \theta_{\text{ATM}}^{\text{input}} = (1 + q^{\text{fit}})/(1 + q^{\text{input}}) < 1$, for $q^{\text{fit}} < 0 < q^{\text{input}}$, can compensate for the reduction due to the matter effect when the hierarchy is inverted. The reduction of the minimum $\Delta \chi^2$ due to the octant degeneracy is strong at $\sin^2 \theta_{\text{ATM}}^{\text{input}} > 0.5$ for the inverted hierarchy, and the increased sensitivity to the mass hierarchy pattern for large $\sin^2 \theta_{\text{ATM}}$ is lost when it is inverted.

In Fig.7, we show the capability of the T2KK experiment to determine the mass hierarchy pattern as contour plots of the minimum $\Delta \chi^2$ value on the parameter space of $\sin^2 2\theta_{\text{RCT}}^{\text{input}}$ and $\delta_{\text{MNS}}^{\text{input}}$. In each figure, the input date are calculated for the model parameters at various $\sin^2 2\theta_{\text{RCT}}^{\text{input}}$ and $\delta_{\text{MNS}}^{\text{input}}$ values, with $\sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.40$ in (a1, b1), $\sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.50$ in (a2, b2), or $\sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.60$ in (a3, b3). The left-hand figures (a1, a2, a3) are for the the normal hierarchy, and the right-hand figures (b1, b2, b3) are for the the inverted hierarchy. The other input parameters are the same as those of Fig.5, and in eq.(27). All the fit parameters are varied freely to minimize the $\Delta \chi^2$ function, under the constraint of the opposite mass hierarchy. The resulting values of minimum $\Delta \chi^2$ are shown as contours for $\Delta \chi^2 = 9, 16, 25$. The contours of Figs.7(a2) and 7(b2) are identical to those of Fig.6 of Ref. [9], which we copy for the purpose of comparison.

It is clearly seen in Fig.7 that the main feature of the T2KK ability for the mass hierarchy determination at $\sin^2 2\theta_{\text{ATM}}^{\text{input}} = 0.96$, $\sin^2 \theta_{\text{ATM}} = 0.4$ (a1, b1) or 0.6 (a3, b3), are not much different from those at $\sin^2 2\theta_{\text{ATM}}^{\text{input}} = 1.0$ (a2, b2), such as the fact the minimum $\Delta \chi^2$ around
\[ \Delta \chi^2 \] 

\[ \sin^2 \theta_{\text{ATM}} \] 

\[ \delta_{\text{MNS}} \] 

\[ \delta_{\text{input}} \sim 0^\circ \] is smaller than that around \( \delta_{\text{MNS}} \sim 180^\circ \). Close examination of Fig.7, however, reveals the followings. In case of the normal hierarchy, \( m_3^2 - m_1^2 > 0 \), the minimum \( \Delta \chi^2 \) grows with growing \( \sin^2 \theta_{\text{ATM}} \), and the mass hierarchy can be determined at 3\( \sigma \) level for \( \sin^2 2\theta_{\text{input}}^{\text{ATM}} \gtrsim 0.07 \) if \( \sin^2 \theta_{\text{input}}^{\text{ATM}} = 0.40 \) (a1), whereas the same holds for \( \sin^2 2\theta_{\text{input}}^{\text{RCT}} \gtrsim 0.04 \) if \( \sin^2 \theta_{\text{input}}^{\text{ATM}} = 0.60 \) (a3). This is mainly because the \( \nu_\mu \to \nu_e \) event rate grows with \( \sin^2 \theta_{\text{ATM}}^{\text{input}} \) and because the presence of the octant degeneracy does not disturb the measurement significantly, as can be seen from the open circle points in Fig.5. In contrast, no significant improvement in the hierarchy discrimination power is found for \( \sin^2 \theta_{\text{input}}^{\text{ATM}} > 0.5 \) in case of the inverted hierarchy. This is because the octant degeneracy between \( \sin^2 \theta_{\text{ATM}}^{\text{fit}} = 0.6 \) and \( \sin^2 \theta_{\text{ATM}}^{\text{fit}} = 0.4 \) allows us to compensate for the matter effect reduction of the \( \nu_\mu \to \nu_e \) rate. We find that the best hierarchy discrimination is achieved at \( \sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.5 \) for all \( \delta_{\text{MNS}} \) values, confirming the trends of Fig.6.

Summing up, the T2KK two detector experiments can resolve the mass hierarchy pattern in the presence of the octant degeneracy. If the hierarchy is normal, the discriminating power grows with increasing \( \sin^2 \theta_{\text{ATM}}^{\text{input}} \). On the other hand, if the hierarchy is inverted, the discriminating power reduces both at \( \sin^2 \theta_{\text{ATM}}^{\text{input}} < 0.5 \) and at \( \sin^2 \theta_{\text{ATM}}^{\text{input}} > 0.5 \): it reduces at \( \sin^2 \theta_{\text{ATM}} < 0.5 \) because of the lower rate of the \( \nu_\mu \to \nu_e \) events, while it reduces at \( \sin^2 \theta_{\text{ATM}} > 0.5 \) because of the octant degeneracy.
Figure 7: The potential of the T2KK experiment to determine the neutrino mass hierarchy. The input data calculated for the normal hierarchy (a1, a2, a3) or for the inverted hierarchy (b1, b2, b3), and the fit has been performed by assuming the wrong hierarchy. In each figure, the minimum \( \Delta \chi^2 \) is obtained for the input data calculated at various \( (\sin^2 2\theta_{\text{input}}^{\text{RCT}}, \delta_{\text{input}}^{\text{MNS}}) \) with \( \sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.40 \) for (a1, b1), \( \sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.50 \) for (a2, b2), or \( \sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.60 \) for (a3, b3). The other input parameters are the same as those of Fig.1. The contours of the minimum \( \Delta \chi^2 \) are shown for \( \Delta \chi^2 = 9, 16, 25 \).
Figure 8: The allowed region in the plane of $\sin^2 2\theta_{RCT}$ and $\delta_{MNS}$ by the T2KK set up of Fig.1, when $\sin^2 \theta_{\text{input}}^{\text{ATM}} = 0.40$ and the hierarchy is normal. The input values of $\sin^2 2\theta_{RCT}$ and $\delta_{MNS}$, $\sin^2 2\theta_{\text{input}}^{\text{RCT}} = 0.06$ or 0.10, $\delta_{\text{input}}^{\text{MNS}} = 0^\circ$ (a), $90^\circ$ (b), $180^\circ$ (c), and $-90^\circ$ (d), are denoted by solid blobs in each figure and the other input parameters are listed in eq.(27). The 1$\sigma$, 2$\sigma$, and 3$\sigma$ contours are shown by solid, dashed, and dotted lines, respectively. The thick (thin) lines are for $\sin^2 2\theta_{\text{input}}^{\text{RCT}} = 0.10$ (0.06). There is no allowed region within 3$\sigma$ when the inverted hierarchy is assumed with fit.

6 CP phase and the octant degeneracy

In this section, we investigate the relation between the CP phase measurement and the octant degeneracy.

Figure 8 shows the potential of the T2KK experiment for measuring $\sin^2 2\theta_{RCT}$ and $\delta_{MNS}$ when $\sin^2 \theta_{\text{input}}^{\text{ATM}} = 0.40$ and the hierarchy is normal, $m_3^2 - m_1^2 > 0$. The input values of $\sin^2 2\theta_{RCT}$ and $\delta_{MNS}$ are denoted by solid blobs in each figure, and the 1$\sigma$, 2$\sigma$, and 3$\sigma$ allowed regions are shown by solid, dashed, and dotted lines, respectively. The thick contours are for $\sin^2 2\theta_{\text{input}}^{\text{RCT}} = 0.10$, and the thin contours are for $\sin^2 2\theta_{\text{input}}^{\text{RCT}} = 0.06$. $\delta_{\text{input}}^{\text{MNS}} = 0^\circ$ in Fig.8(a), $90^\circ$ in (b), $180^\circ$ in (c), and $-90^\circ$ in (d). There is no additional allowed region within 3$\sigma$ when the inverted hierarchy is assumed in the fit, in accordance with Fig.7(a1).

When we compare the contours of Fig.8 with the corresponding ones in Fig.8 of Ref. [9] for $\sin^2 \theta_{\text{input}}^{\text{ATM}} = 0.5$, we can clearly identify the islands due to the octant degeneracy. When $\sin^2 2\theta_{\text{input}}^{\text{RCT}} = 0.10$, the thick contours shows no island at $\delta_{\text{input}}^{\text{MNS}} = 90^\circ$, but 3$\sigma$ islands appear at all
the other $\delta^{\text{input}}_{\text{MNS}}$ cases, which is consistent with the result of Fig.2(a). In case of $\sin^2 \theta^{\text{input}}_{\text{ATM}} = 0.06$, the contours have 3$\sigma$ islands for all $\delta^{\text{input}}_{\text{MNS}}$ cases and a clear 2$\sigma$ island at $\delta^{\text{input}}_{\text{MNS}} = -90^\circ$, again consistent with Fig.2(a). Close examination of the location of the islands reveals that their center is at around $\sin^2 2\theta_{\text{fit}}^{\text{RCT}} = \sin^2 2\theta_{\text{input}}^{\text{RCT}} (0.4)/(0.6)$, as expected by eq.(28). The existence of the islands due to the octant degeneracy hence reduces our capability of measuring $\sin^2 2\theta_{\text{RCT}}$ significantly.

It is remarkable that the octant degeneracy does not jeopardize the T2KK capability of determining the CP phase, $\delta_{\text{MNS}}$: the islands in Fig.8 have the $\delta_{\text{MNS}}$ values consistent with its input values. This is because the coefficients of both $\sin \delta_{\text{MNS}}$ and $\cos \delta_{\text{MNS}}$ in the $\nu_\mu \rightarrow \nu_e$ oscillation probability is not sensitive to the octant degeneracy, as explained in eq.(14). The results we found in Fig.8 confirms the validity of our approximation for the T2KK experiments.

Figure 9 also shows the potential of the T2KK experiment for measuring $\sin^2 2\theta_{\text{RCT}}$ and $\delta_{\text{MNS}}$, but for $\sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.60$. There is no allowed region within 3$\sigma$ when the inverted hierarchy is assumed in the fit, as can be seen from Fig.7(a3).

Comparing the contours of Fig.9 with the corresponding ones in Fig.8 of Ref. [9] for $\sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.5$, we can again identify the islands due to the octant degeneracy. When $\sin^2 2\theta_{\text{RCT}}^{\text{input}} = 0.10$, the thick contours shows no island at $\delta^{\text{input}}_{\text{MNS}} = \pm 90^\circ$, but 3$\sigma$ islands appear at the other $\delta^{\text{input}}_{\text{MNS}}$ cases. In case of $\sin^2 \theta_{\text{RCT}}^{\text{input}} = 0.06$, the contours have 3$\sigma$ islands for all $\delta^{\text{input}}_{\text{MNS}}$ cases, but there is no 2$\sigma$ island. These results are consistent with the result of Fig.2(a). The location of the center of the islands is at around $\sin^2 2\theta_{\text{fit}}^{\text{RCT}} = \sin^2 2\theta_{\text{input}}^{\text{RCT}} (0.6)/(0.4)$, as expected by eq.(28).
The capability of measuring $\sin^2 2\theta_{\text{RCT}}$ for $\sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.60$ is also reduced by the octant degeneracy, which is the same as that for $\sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.40$. However, the octant degeneracy does not disturb the T2KK capability of determining the CP phase.

7 Summary

There are three types of ambiguity in the neutrino parameter space. The first one is from the sign of the larger mass-squared difference, which is related to the mass hierarchy pattern. The second one is from the combination of the unmeasured parameters, the leptonic CP phase ($\delta_{\text{MNS}}$) and the mixing angle $\theta_{\text{RCT}}$, which resides at the upper-right corner of the MNS matrix [1]. In the previous studies [8, 9], we showed that the idea [10] of placing a 100kton-level water Čerenkov detector in Korea along the T2K neutrino beam at $L = 1000\text{km}$, the T2KK experiment [13] can solve these ambiguities. The last ambiguity is in the value of the $\theta_{\text{ATM}}$, which dictates the atmospheric neutrino observation [2] and the long base-line neutrino oscillation experiment [3, 4]. If the mixing angle $\theta_{\text{ATM}}$, is not $45^\circ$, there is a two-fold ambiguity between “$\theta_{\text{ATM}}$” and “$90^\circ - \theta_{\text{ATM}}$”, the octant degeneracy [16].

In this paper, we focus on the physics potential of the T2KK experiment for solving the octant degeneracy. In our semi-quantitatively analysis, we follow the strategy of Ref. [8, 9] where we adopt SK as a near side detector and postulate a 100 kton water Čerenkov detector at $L = 1000\text{km}$, and the J-PARC neutrino beam orientation is adjusted to $3.0^\circ$ at SK and $0.5^\circ$ at the Korean detector site.

If the value of $\sin^2 2\theta_{\text{ATM}}$ is 0.99, which is 1% smaller than the maximal mixing, the value of $\sin^2 \theta_{\text{ATM}}$ is $\sin^2 \theta_{\text{ATM}} = 0.45$ or 0.55, which differ by 20%. Therefore, we also investigate the impacts of the octant degeneracy on the physics potential for the mass hierarchy determination and the CP phase measurement by T2KK, because the leading term of $\nu_\mu \rightarrow \nu_e$ oscillation probability is proportional to $\sin^2 \theta_{\text{ATM}}$, not $\sin^2 2\theta_{\text{ATM}}$.

When we include the constraint for the value of $\sin^2 \theta_{\text{RCT}}$, which will be obtained from the future reactor experiments [25]. the octant degeneracy between $\sin^2 \theta_{\text{ATM}} = 0.40$ and 0.60 can be resolved at $3\sigma$ level for $\sin^2 2\theta_{\text{RCT}} > 0.12$ (0.08) after 5 years exposure with $1.0 \times 10^{21}$ POT/year, if the hierarchy is normal, see Fig.1 and Fig.2. We find that the contribution from the second maximum of the $\nu_e \rightarrow \nu_\mu$ oscillation probability at the far detector ($L = 1000\text{km}$) plays an important role for solving the octant degeneracy. It is also found that the octant degeneracy cannot be solved without the contribution from future reactor experiments.

We also investigate the impact of the octant degeneracy in the determination of the mass hierarchy pattern. The T2KK power of resolving the mass hierarchy pattern is proportional to the value of $\sin^2 \theta_{\text{RCT}}^{\text{input}}$ for the normal hierarchy, see Fig.5, because the $\nu_\mu \rightarrow \nu_e$ rate is proportional to $\sin^2 \theta_{\text{ATM}}^{\text{input}}$. When the mass hierarchy is normal, we can determine the mass hierarchy at $3\sigma$ level for $\sin^2 2\theta_{\text{RCT}}^{\text{input}} \gtrsim 0.07$ if $\sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.40$, Fig.7(a1), whereas the same holds for $\sin^2 2\theta_{\text{RCT}}^{\text{input}} \gtrsim 0.04$ if $\sin^2 \theta_{\text{ATM}}^{\text{input}} = 0.60$, Fig.7(a3). On the other hand, if the hierarchy is inverted, $\sin^2 \theta_{\text{ATM}} = 0.5$ is found to be the optimal case for the mass hierarchy determination,
see Fig.6, because of the lower rate of the $\nu_\mu \to \nu_e$ events for $\sin^2 \theta^{\text{input}}_{\text{ATM}} < 0.5$ and the octant degeneracy for $\sin^2 \theta^{\text{input}}_{\text{ATM}} > 0.5$.

Finally, we check the effect of the octant degeneracy for the CP phase measurement, see Fig.8 and Fig.9. The CP phase can be constrained to $\pm 30^\circ$ at $1\sigma$ level for $\sin^2 2\theta_{\text{ATM}} = 0.96$, even if we cannot distinguish between $\sin^2 \theta_{\text{ATM}} = 0.4$ or $0.6$. The error does not increase from that for $\sin^2 \theta_{\text{ATM}} = 0.5$, because the coefficients of both sine and cosine term of $\delta_{\text{MNS}}$ in the $\nu_\mu \to \nu_e$ oscillation probability are not sensitive to the octant degeneracy.

Acknowledgments

We thank our colleagues Y. Hayato, A.K. Ichikawa, K. Kaneyuki, T. Kobayashi, and T. Nakaya, from whom we learn about K2K and T2K experiments. We are also grateful to K-i. Senda and T. Takeuchi for useful discussions and comments. The work is supported in part by the Core University Program of JSPS. The numerical calculations were carried out on Altix3700 BX2 at YITP in Kyoto University.

Note Added

When finalizing the manuscript, we learned that a similar study has been performed by T. Kajita, et al. [28].
