are used to obtain the product of the CKM matrix element $|V_{cb}|$ times the form factor at the zero

$B \to D \ell \nu$ decays to $D_{\ell} \ell$ ($\ell = e$ or $\mu$) are selected by reconstructing $D_{\ell} \ell$ and $D_{\ell} \ell$ combinations from a sample of 230 million $\Upsilon(4S) \to B \bar{B}$ decays recorded with the BABAR detector at the PEP-II $e^+ e^-$ collider at SLAC. A global fit to these samples in a 3-dimensional space of kinematic variables is used to determine the branching fractions $B(B^- \to D_{\ell} \ell) = (2.34 \pm 0.03 \pm 0.13)\%$ and $B(B^- \to D_{0}^{*+} \ell \nu) = (5.40 \pm 0.02 \pm 0.21)\%$ where the errors are statistical and systematic, respectively. The fit also determines form factor parameters in a HQET-based parameterization, resulting in $\rho_{D_{\ell}} = 1.20 \pm 0.04 \pm 0.07$ for $B \to D \ell \nu$ and $\rho_{D_{0}} = 1.22 \pm 0.02 \pm 0.07$ for $B \to D^{*} \ell \nu$. These values are used to obtain the product of the CKM matrix element $|V_{cb}|$ times the form factor at the zero.
I. INTRODUCTION

The study of semileptonic decays of heavy quarks provides the cleanest avenue for the determination of several elements of the Cabibbo-Kobayashi-Maskawa matrix [1], which are fundamental parameters in the standard model of particle physics. The coupling strength of the weak $b \to c$ transition is proportional to $|V_{cb}|$, which has been measured in both inclusive semileptonic $B$ decays [2] and in the exclusive transitions $B \to D^{(s)}/D^*\ell\nu$ [3, 6–10] ($\ell = e$ or $\mu$ and charge conjugate modes are implied). The inclusive and exclusive determinations of $|V_{cb}|$ rely on different theoretical calculations. The former employs a parton-level calculation of the decay rate organized in a double expansion in $\alpha_S$ and in inverse powers of $m_b$, the $b$-quark mass. The latter relies on a parameterization of the decay form factors using Heavy Quark Symmetry and a non-perturbative calculation of the form factor normalization at the zero recoil (maximum squared momentum transfer) point. The theoretical uncertainties in these two approaches are independent. The inclusive and exclusive experimental measurements use different techniques and have negligible statistical overlap, and thus have largely uncorrelated uncertainties. This independence makes the comparison of $|V_{cb}|$ from inclusive and exclusive decays a powerful test of our understanding of semileptonic decays. The latest determinations [11] differ by more than two standard deviations ($\sigma$), and the inclusive determination is currently more than twice as precise as the exclusive determination. Improvements in the measurements of exclusive decays will strengthen this test. This is particularly true for the $B \to D^{s}\ell\nu$ decay, where the experimental uncertainties dominate the determination of $|V_{cb}|$. For the decay $B^0 \to D^{s+}\ell\nu$, the experimental situation needs clarification, as existing measurements are in poor agreement with each other [11]. Finally, precise measurements of semileptonic $B$ decays to charm are needed to further improve determinations of $|V_{ub}|$, where $B \to D^{(*)}\ell\nu$ decays are the principal background.

Semileptonic $b \to c$ transitions result in the production of a charm system that cascades down to the ground state $D^0$ or $D^+$ mesons. Most previous analyses have focused on reconstructing separately the exclusive decays $B \to D^{(s)}\ell\nu$ [3, 7–10] and $B \to D\ell\nu$ [3–5]. The $B \to D^{s}\ell\nu$ analyses involve reconstruction of the soft transition pion from the decay $D_s \to D\pi$, which is at the limit of detector acceptance; determination of the reconstruction efficiency for these pions introduces significant systematic uncertainty. Studies of the exclusive decay $B \to D^\ast\ell\nu$ suffer from large feed-down background from $B \to D^{s}\ell\nu$ decays where the transition pion is undetected.

In this analysis we reconstruct $D^0\ell$ and $D^{s}\ell$ pairs and use a global fit to their kinematic properties to determine the branching fractions and form factor parameters of the dominant semileptonic decays $B \to D^{(s)}\ell\nu$ and $B \to D^{s+}\ell\nu$. The reconstructed $D\ell$ samples contain, by design, the feed-down from all the higher mass states (apart from decays of the type $B \to D^{s+}X\ell\nu$ [12]). Kinematic restrictions are imposed to reduce the contribution of backgrounds from semileptonic decays to final state hadronic systems more massive than $D^*$ and from other sources of $D\ell$ combinations. Distributions from selected events are binned in the 3-dimensional space described below. The electron and muon samples are input into separate fits, in which isospin symmetry is assumed for the semileptonic decay rates. Semileptonic decays are produced via a spectator diagram in which the heavy quark decays independently; strong interaction corrections to this process conserve isospin. As a result, we constrain semileptonic decay rates for $B^-$ and $B^0$ to be equal, e.g., $\Gamma(B^- \to D^0\ell\nu) = \Gamma(B^0 \to D^+\ell\nu)$. This substantially reduces statistical uncertainties on the fitted parameters. Systematic uncertainties associated with the modeling of the signal and background processes, the detector response, and uncertainties on input parameters are determined, along with their correlations between the electron and muon samples. The fitted results are then combined using the full covariance matrix of statistical and systematic errors. For both $B \to D\ell\nu$ and $B \to D^{s}\ell\nu$ decays, the fitted branching fractions and form factor parameters are used to determine the products $G(1)|V_{cb}|$ and $F(1)|V_{cb}|$. These measurements, along with theoretical input on the form factor normalizations $G(1)$ and $F(1)$ at the zero recoil point, allow determinations of $|V_{cb}|$.

The approach taken in this study has some similarity to that of Ref. [6], where the branching fractions for $B \to D\ell\nu$ and $B \to D^{s}\ell\nu$ are measured simultaneously. However, Ref. [6] reconstructs semileptonic $B$ decays in events in which the second $B$ meson is fully reconstructed. That approach allows the use of the missing mass squared as a powerful discriminant. This analysis provides modest discrimination between the different
semileptonic decays on an event-by-event basis, but results in a much larger statistical sample and enables the measurement of form factor parameters.

The remaining sections of this paper are organized as follows. In Sec. II we describe the BaBar detector and the samples of BaBar data and simulated events used in the analysis. The event selection and the distributions that are input to the global fit are discussed in Sec. III. We give the parameterization of the form factors of $B \to D^{(*)}\pi\pi\pi$ decays and the modeling of semileptonic $B$ decays to $D^{(*)}\pi$ and $D^{(*)}\pi\pi$ states in Sec. IV. The global fit strategy and results are given in Sec. V, and the evaluation of systematic uncertainties is detailed in Sec. VI. Sec. VII presents the determination of $|V_{cb}|$ from the fitted results. The final section (VIII) discusses the results and provides averages with previous BaBar measurements.

II. THE BABAR DETECTOR AND DATASET

The data used in this analysis were collected with the BaBar detector at the PEP-II storage ring between 1999 and 2004. PEP-II is an asymmetric collider; the center-of-mass of the colliding $e^+e^-$ moves with velocity $\beta = 0.49$ along the beam axis in the laboratory rest frame. The data collected at energies near the peak of the $T(4S)$ resonance (on-peak) correspond to 207 fb$^{-1}$ or 230 million $B\bar{B}$ decays. Data collected just below $B\bar{B}$ threshold (off-peak), corresponding to 21.5 fb$^{-1}$, are used to subtract the $e^+e^- \to q\bar{q} (q = u,d,s,c)$ background under the $T(4S)$ resonance.

The BaBar detector is described in detail elsewhere [13]. It consists of a silicon vertex tracker (SVT), a drift chamber (DCH), a detector of internally reflected Cherenkov light (DIRC), an electromagnetic calorimeter (EMC) and an instrumented flux return (IFR). The SVT and DCH operate in an axial magnetic field of 1.5 T and provide measurements of the positions and momenta of charged particles, as well as of their ionization energy loss ($dE/dx$). Energy and shower shape measurements for photons and electrons are provided by the EMC. The DIRC measures the angle of Cherenkov photons emitted by charged particles traversing the fused silica radiator bars. Charged particles that traverse the EMC and showering hadrons are measured in the IFR as they penetrate successive layers of the return yoke of the magnet.

Simulated events used in the analysis are generated using the EVTGEN [14] program, and the generated particles are propagated through a model of the BaBar detector with the GEANT4 [15] program and reconstructed using the same algorithms used on BaBar data. The form factor parameterization [16] used in the simulation for $B \to D^{(*)}\pi\pi\pi$ decays is based on Heavy Quark Effective Theory (HQET) [17], while the ISGW2 model [18] is used for $B \to D\pi\pi$ and $B \to D^{(*)}\pi\pi$ decays, where $D^{(*)}$ is one of the four $P$-wave charm mesons as described in Sec. III B. These are subsequently reweighted to the forms given in Sec. IV. For non-resonant $B \to D^{(*)}\pi\pi\pi$ decays, the Goity-Roberts model [19] is used. In order to saturate the inclusive semileptonic $b \to c\ell\nu$ decay rate we include a contribution from $B \to D^{(*)}\pi\pi\pi\ell$ decays; a variety of models are considered for this purpose. The branching fractions for $B$ and charm decays in the simulation are rescaled to the values in Ref. [11]. In addition, the momentum spectra for $D^0$ and $D^+$ from $B \to DX$ and $B \to DX$ decays are adjusted to agree with the corresponding measured spectra from Ref. [20]. This adjustment is done only for background processes.

The simulation of the detector response provided by the GEANT4-based program is further adjusted by comparing with BaBar data control samples. In particular, the efficiency of charged track reconstruction is modified by 1-2%, depending on momenta and event multiplicity, based on studies of multi-hadron events and 1-versus-3 prong $e^+e^- \to \tau^+\tau^-$ events. The efficiencies and misidentification probabilities of the particle identification (PID) algorithms used to select pions, kaons, electrons and muons (see Sec. III) are adjusted based on studies of samples of $e^+e^- \to e^+e^-\gamma$ and $e^+e^- \to \mu^+\mu^-\gamma$, and several samples reconstructed without particle identification: 1-versus-3 prong $e^+e^- \to \tau^+\tau^-$ events, $K_S^0 \to \pi^+\pi^-$, $D^{(*)} \to D^0\pi^+ \to (K^-\pi^+)\pi^+$ and $A \to p\pi^-$.

III. EVENT SELECTION

A. Preselection of $D\ell$ candidates

We select multi-hadron events by requiring at least three good-quality charged tracks, a total reconstructed energy in the event exceeding 4.5 GeV, the second normalized Fox-Wolfram moment $R_2 < 0.5$, and the distance between the interaction point and the primary vertex of the $B$ decay to be less than 0.5 cm (6.0 cm) in the direction transverse (parallel) to the beam line. In these events an identified electron or muon candidate must be present, along with a candidate $D$ meson decay. Candidate electrons are identified using a likelihood ratio based on the shower shape in the EMC, $dE/dx$ in the tracking detectors, the Cherenkov angle and the ratio of EMC energy to track momentum. The electron identification efficiency is 94% within the acceptance of the calorimeter, and the pion misidentification rate is 0.1%. Muon candidates are identified using a neural network that takes input information from the tracking detectors, EMC, and IFR. The muon identification efficiency rises with momentum to reach a plateau of 70% for laboratory momenta above 1.4 GeV/$c$, and the pion misidentification rate is 3%.

Kaon candidates are required to satisfy particle identification criteria based on the $dE/dx$ measured in the tracking detectors and the Cherenkov angle measured in the DIRC. Each kaon candidate is combined with one or two charged tracks of opposite sign to form a $D^0 \to K^-\pi^+$ or $D^+ \to K^-\pi^+\pi^+$ candidate. Those
combinations with invariant masses in the range $1.840 < m_{K\pi} < 1.888$ GeV/c² are considered as $D^0$ candidates and those in the range $1.845 < m_{K\pi\pi} < 1.893$ GeV/c² as $D^+$ candidates, respectively. Combinations in the “sideband” mass regions $1.816 < m_{K\pi} < 1.840$ GeV/c² and $1.888 < m_{K\pi} < 1.912$ GeV/c² ($1.821 < m_{K\pi\pi} < 1.845$ GeV/c² and $1.893 < m_{K\pi\pi} < 1.917$ GeV/c²) are used to estimate the combinatorial background.

The charge of the kaon candidate is required to have the same sign as that of the candidate lepton. Each $D\ell$-lepton combination in an event is fitted to both $\bar{B} \rightarrow D\ell$ and $D \rightarrow K^{-}\pi^{+}(\pi^{+})$ vertices using the algorithm described in Ref. [22]. The fit probabilities are required to exceed 0.01 for the $\bar{B} \rightarrow D\ell$ and $\bar{B} \rightarrow D^{+}\ell$ vertices and 0.001 for the $D^0$ and $D^+$ decay vertices. We require the absolute value of the cosine of the angle between the $D\ell$ momentum vector and the thrust axis of the remaining particles in the event to be smaller than 0.92 to further reduce background, most of which comes from $e^+e^- \rightarrow q\bar{q}$ ($q = u, d, s, c$) events.

The signal yields are determined by subtracting the estimated combinatorial background from the number of $D$ candidates in the peak region. The combinatorial background is estimated using the number of candidates in the $D$ mass sideband regions scaled by the ratio of the widths of the signal and sideband regions. This is equivalent to assuming a linear dependence of the combinatorial background on invariant mass. The change in the yields is negligible when using other assumptions for the background shape. Candidates from $e^+e^- \rightarrow q\bar{q}$ events are statistically removed from the data sample by subtracting the distribution of candidates observed in the data collected at energies below $B\bar{B}$ threshold (off-peak), after scaling these data by the factor $r_C = (\mathcal{L}_{on} s_{off}) / (\mathcal{L}_{off} s_{on})$ to account for the difference in luminosity and the dependence of the annihilation cross-section on energy. The selection criteria listed above were determined using simulated $B\bar{B}$ events and off-peak data to roughly maximize the statistical significance of the $D\ell$ signal yields in $e^+e^- \rightarrow B\bar{B}$ events. They have an overall efficiency of 80% (76%) for $\bar{B} \rightarrow D^0 X(\pi\pi) (\bar{B} \rightarrow D^{+}\ell X(\pi\pi)$ decays with $p_{T\ell}$, the lepton momentum magnitude in the center-of-mass (CM) frame, in the range 0.8–2.8 GeV/c.

The invariant mass distributions for the $D^0$ and $D^+$ candidates, after off-peak subtraction, are shown in Fig. 1 for two kinematic subsets representing regions with good and poor signal-to-background ratios. The small differences in peak position and combinatorial background level have negligible impact on the analysis due to the sideband subtraction described above and the wide signal window.

The $D^0\ell$ and $D^{+}\ell$ candidates are binned in three kinematic variables:

- $p_{T\ell}$, the $D$ momentum in the CM frame;
- $p_{T\ell}$, the lepton momentum in the CM frame;
- $\cos \theta_{B-D\ell} \equiv (2E_{B}E_{D\ell} - m_{B}^2 - m_{D\ell}^2) / (2p_{T B}p_{T\ell})$.

The binning in these three variables is discussed in Sec. III.C.

B. Sources of $D\ell$ candidates

There are several sources of $D\ell$ candidates that survive the $D$-mass sideband and off-peak subtractions. In both
the $D^0$ and $D^+$ samples we group them as follows ($\bar{B}$ represents both $B^-$ and $B^0$):

(i) $\bar{B} \to D \ell \nu$

(ii) $\bar{B} \to D^* \ell \nu$

(iii) $\bar{B} \to D^{(*)}(n\pi)\ell\nu$, which includes

- The P-wave $D^{**}$ charm mesons. In the framework of HQET, the P-wave charm mesons are categorized by the angular momentum of the light constituent, $j_\ell$, namely $j_\ell^0 = 1/2^-$ doublet $D_0^*$ and $D_1^*$ and $j_\ell^2 = 3/2^-$ doublet $D_1$ and $D_2^*$ [23].
- Non-resonant $\bar{B} \to D^{(*)}\pi\ell\nu$.
- Decays of the type $\bar{B} \to D^{(*)}\pi\pi\ell\nu$; the modeling of these is discussed in Sec. IV D.

(iv) Background from $B\bar{B}$ events in which the lepton and $D$ candidates do not arise from a single semileptonic $\bar{B}$ decay. These include (in order of importance)

- Direct leptons from $\bar{B} \to X\ell\nu$ decays combined with a $D$ from the decay of the other $B$ meson in the event. Roughly one third of this background comes from events in which $B^*\bar{B}^0$ mixing results in the decay of two $\bar{B}^0$ mesons. Most of the remaining contribution comes from CKM-suppressed $B \to DX$ transitions.
- Uncorrelated cascade decays. In this case the lepton mostly comes from the decay of an anti-charm meson produced in the $B$ decay and the $D$ arises from the decay of the other $\bar{B}$ meson in the event.
- Correlated cascade decays, in which the lepton and $D$ candidates come from the same parent $\bar{B}$ meson. These are mainly $\bar{B} \to D\bar{D}(X)$ and $\bar{B} \to D(X)\tau\nu$ decays, with the lepton coming from the decay of an anti-charm meson or tau.
- Mis-identified lepton background. The probability of a hadron being misidentified as a lepton is negligible for electrons but not for muons.

As mentioned previously, the same decay widths are imposed for the semileptonic transitions of $\bar{B}^0$ and $B^-$. For the background processes (source iv) no such requirement is imposed.

C. Kinematic restrictions

Despite the use of the best available information for calculating the background and $\bar{B} \to D^{(*)}(n\pi)\ell\nu$ distributions, these components suffer from significant uncertainties. We therefore restrict the kinematic range of the variables used in the fit to reduce the impact of these uncertainties while preserving sensitivity to the $\bar{B} \to D \ell\nu$ and $\bar{B} \to D^* \ell\nu$ branching fractions and form factor parameters. We require $-2 < \cos\theta_{B^-D\ell} < 1.1$ and place restrictions on $p_D^\ell$ and $p_\ell^\ell$, rejecting regions where the signal decays are not dominant. This results in the ranges $1.2 \text{ GeV}/c < p_D^\ell < 2.35 \text{ GeV}/c$ and $0.8 \text{ GeV}/c < p_\ell^\ell < 2.25 \text{ GeV}/c$. The yield within this region is $4.79 \times 10^5$ (2.95 $\times 10^5$) candidates in the $D^0\ell$ ($D^+\ell$) sample with a statistical uncertainty of 0.26% (0.66%).

The data are binned finely enough to have good sensitivity to the fit parameters while maintaining adequate statistics per bin. Table I gives the binning used in the fit. We avoid setting a bin edge at $\cos\theta_{B^-D\ell} = 1$ to reduce our sensitivity to the modeling of the resolution in this variable, since the $\bar{B} \to D \ell\nu$ decay distribution has a sharp cut-off at this point.

![FIG. 2: (Color online) Distribution of $p_D^\ell$ vs. $p_\ell^\ell$ for $D^0\ell$ candidates after sideband subtraction. The shaded boxes have area proportional to the number of entries. The plots show simulated candidates for (a) $\bar{B} \to D\ell\nu$, (b) $\bar{B} \to D^*\ell\nu$ and (c) other (sources iii and iv combined), and for data after off-peak subtraction (d). The binning given in Table I is used and only candidates that satisfy $0.0 < \cos\theta_{B^-D\ell} < 1.1$ are plotted.](image)
Fig. 2 to illustrate the separation power in these variables. The distributions for the $D^0\mu$ sample (not shown) are similar. The one-dimensional projections of the $D\mu$ samples are shown in Figs. 3 and 4. The difference in the size of the $\bar{B} \to D^* \ell\nu$ components in $D^0\ell$ and $D^+\ell$ distributions is due to the fact that $D^{*0}$ does not decay to $D^+$.

### IV. MODELING OF SEMILEPTONIC B DECAYS

In our fully simulated event samples $\bar{B} \to D\ell\nu$ and $\bar{B} \to D^{*}\ell\nu$ decays were generated using the ISGW2 model [18]. For $\bar{B} \to D^*\ell\nu$ decays, an HQET model was used with a linear form factor parameterization. We re-weight all these decays using the formulae given in the following subsections. The histograms in Figs. 3 and 4 are re-weighted.

#### A. $\bar{B} \to D\ell\nu$ decays

The differential decay rate is given by [17]

$$
\frac{d\Gamma(\bar{B} \to D\ell\nu)}{dw} = \frac{G_F^2 |V_{cb}|^2 m_B^3 r^3 (w^2 - 1)^{3/2}}{48\pi^3} \times [(1 + r) h_+(w) - (1 - r) h_-(w)]^2,
$$

where $G_F$ is the Fermi constant, $h_+(w)$ and $h_-(w)$ are the form factors, $r \equiv m_D/m_B$ is the mass ratio and $m_B$ and $m_D$ are the $B$ and $D$ meson masses, respectively. The velocity transfer $w$ is defined as

$$
w \equiv v_B \cdot v_D, $$

as
where $v_B$ and $v_D$ are the 4-velocities of the $B$ and $D$ mesons, respectively. In the $B$ rest frame $w$ corresponds to the Lorentz boost of the $D$ meson. In the HQET model, the form factors are given by [16]

$$h_+(w) = G(1) \times \frac{1}{1 - 8 \rho_D^2 z + (51 \rho_D^2 - 10) z^2 - (252 \rho_D^2 - 84) z^3}$$  \hspace{1cm} (3)

and

$$h_-(w) = 0,$$  \hspace{1cm} (4)

where $z = (\sqrt{w + 1} - \sqrt{2})/(\sqrt{w + 1} + \sqrt{2})$ and $\rho_D^2$ and $G(1)$ are, respectively, the form factor slope and normalization at $w = 1$.

The above formulae neglect the lepton mass $m_\ell$. Muon mass effects need to be included to achieve precision at the few percent level on the form factor parameters. Allowing for non-zero lepton mass introduces additional terms in the phase space and form factor expressions [24] that can be included by multiplying the decay rate formula by the following factor:

$$W_D = \left(1 - \frac{1}{1 + r^2 - 2rw m_B^2} \frac{m_B^2}{m^2} \right)^2 \left[1 + K_D(w) \frac{m^2_B}{m^2_B} \right]$$  \hspace{1cm} (5)

where

$$K_D(w) = \left[1 + 3 \left(1 - r \right)^2 \frac{w + 1}{w - 1} \right] \frac{1}{2(1 + r^2 - 2rw)}.$$  \hspace{1cm} (6)

### B. $\overline{B} \rightarrow D^* \ell \nu \overline{\nu}$ decays

We need three additional kinematic variables to describe this decay. A common choice is $\theta_\ell$, $\theta_V$ and $\chi$, 

FIG. 4: (Color online) Projections onto individual kinematic variables of the data after off-peak subtraction and the results of the fit: (a,d) lepton and (b,e) $D$ momentum in the CM frame, and (c,f) $\cos \theta_{B-D\ell}$. The points show data for accepted $D^0 \mu$ (a,b,c) and $D^+ \mu$ (d,e,f) candidates, and the histograms show the individual fit components (from top to bottom): $\overline{B} \rightarrow D\mu \nu$, $\overline{B} \rightarrow D^* \mu \nu$, $\overline{B} \rightarrow D^{(*)}(n\pi)\mu \nu$ and other $B\overline{B}$ background. The ratio of data to the sum of the fitted yields is shown below each plot.
shown in Fig. 5, and defined as

- \( \theta_\ell \): the angle between the lepton and the direction opposite the \( B \) meson in the \( W \) rest frame.
- \( \theta_V \): the angle between the \( D \) meson and the direction opposite the \( B \) meson in the \( D^* \) rest frame.
- \( \chi \): the azimuthal angle between the planes formed by the \( W-\ell \) and \( D^*-D \) systems in the \( B \) rest frame.

The differential decay rate is given by [17]

\[
\frac{d\Gamma(\bar{B} \to D^*\pi\tau)}{dw \, d\cos \theta_V \, d\cos \theta_R \, d\chi} = \frac{3G_F^2}{4(4\pi)^3} |V_{cb}|^2 m_B m_B^* \sqrt{w^2 - 1}(1 + r^{*2} - 2r^*w) \times \]

\[
\left[ (1 - \cos \theta_\ell)^2 \sin^2 \theta_V |H_+(w)|^2 + (1 + \cos \theta_\ell)^2 \sin^2 \theta_V |H_-(w)|^2 + 4 \sin \theta_\ell \cos \theta_\ell \sin \theta_V \cos \chi |H_0(w)|^2 \right] \frac{1}{1 - r^*} \left( 1 + \frac{w - 1}{w + 1} R_3(w) \right),
\]

where \( H_i(w) \) are form factors, \( r^* = m_{D^*}/m_B \) and \( m_{D^*} \) is the \( D^* \) meson mass. The \( H_i(w) \) are usually written in terms of one form factor \( h_{A_i}(w) \) and two form factor ratios, \( R_1(w) \) and \( R_2(w) \), as follows:

\[
H_i = -m_B \frac{R^*(1 - r^{*2})(w + 1)}{2\sqrt{1 + r^{*2} - 2r^*w}} h_{A_i}(w) \tilde{H}_i(w),
\]

where \( R^* = (2\sqrt{m_B m_{D^*}})/(m_B + m_{D^*}) \) and

\[
\tilde{H}_i(w) = \sqrt{1 + r^{*2} - 2r^*w} \left( 1 \mp \sqrt{\frac{w - 1}{w + 1}} R_3(w) \right),
\]

\[
\tilde{H}_0(w) = 1 + \frac{w - 1}{1 - r^*} (1 - R_2(w)).
\]

The form factor ratios have a modest dependence on \( w \), estimated [16] as

\[
R_1(w) = R_1 - 0.12(w - 1) + 0.05(w - 1)^2, \quad R_2(w) = R_2 + 0.11(w - 1) - 0.06(w - 1)^2.
\]

The form used for \( h_{A_i}(w) \) is [16]

\[
h_{A_i}(w) = F(1) \times \left[ 1 - 8 \rho_{D^*}^2 z + (53 \rho_{D^*}^2 - 15) z^2 - (231 \rho_{D^*}^2 - 91) z^3 \right],
\]

where \( \rho_{D^*}^2 \) and \( F(1) \) are, respectively, the form factor slope and normalization at \( w = 1 \).

Non-zero lepton mass is accounted for by multiplying the decay rate formula by the factor

\[
W_{D^*} = \left( 1 - \frac{1}{1 + r^{*2} - 2r^*w} m_B^2 \right)^2 \left[ 1 + \kappa_{D^*}(w) \frac{m_B^2}{m_{B^*}^2} \right],
\]

where

\[
\kappa_{D^*}(w) = \left[ 1 + \frac{3}{2} \frac{\tilde{H}_0^2}{H_+^2 + H_0^2} \right] \frac{1}{2(1 + r^{*2} - 2r^*w)}.
\]

We take \( R_3(w) = 1; \) this approximation has a negligible impact on our fit results.

C. \( \bar{B} \to D^{(*)}\pi\tau \) decays

The four P-wave \( D^{**} \) states have been measured in semileptonic decays [25–27]. The decays \( \bar{B} \to D^{**}\pi\tau \) are modeled following an HQET-inspired form factor parameterization given in Ref. [23]. Detailed formulae are given in Appendix A. We use the approximation \( B_1 \) of this model for our main fit and use the approximation \( B_0 \) to evaluate the uncertainty due to the approximation. The slope of the form factors versus \( w \) is parameterized by \( \tau^* \), which we set to \(-1.5\) and vary between \(-1.0\) and \(-2.0\) to study systematic uncertainties (Table II).

To parameterize the \( \bar{B} \to D^{(*)}\pi\tau \) decay branching fractions we define five branching ratio:

\[
f_{D\pi/D^*}^{D^{(*)}\pi\tau} \equiv \frac{B(B^- \to D^{(*)}\pi\tau)}{B(B^- \to D^0\pi\tau)},
\]

\[
f_{D^*\pi/D^0}^{D^{(*)}\pi\tau} \equiv \frac{B^{NR}(B^- \to D^{*+}\pi^-\tau)}{B(B^- \to D^0\pi\tau)},
\]

\[
f_{D^*\pi/D^0}^{D^{(*)}\pi\tau} \equiv \frac{B^{NR}(B^- \to D^{*+}\pi^-\tau)}{B(B^- \to D^0\pi\tau)},
\]

\[
f_{D^{(*)}\pi/D^0}^{D^{(*)}\pi\tau} \equiv \frac{B(B^- \to D^{(*)}\pi\tau)}{B(B^- \to D^{(*)}\pi\tau) + B(B^- \to D^0\pi\tau)}.
\]
where NR stands for “non-resonant” decays, which are assumed to be isospin-invariant. The quantity \( f_{D^*_1/D_1} \) is the ratio between two broad states, \( f_{D^*_{π/π}D_2} \) is between two broad states decaying to \( Dπ \) and the other two ratios are between broad and narrow states. With these definitions the branching fractions for individual modes can be related to the total branching fraction \( \mathcal{B}(B^− \to D^{(*)}_0 π(τ)) \equiv \mathcal{B}(B^− \to Dπτ) + \mathcal{B}(B^− \to D^*πτ). \) We combine a new measurement \([6]\) with the world average \([11]\) to determine the value given in Table II.

To estimate the branching fraction ratios, we average several measurements \([25−28]\) to find

\[
\begin{align*}
\mathcal{B}(B^− \to D^{0}_1 τ(τ)) &= 0.0042 \pm 0.0004, \\
\mathcal{B}(B^− \to D^{0}_2 τ(τ)) &= 0.0031 \pm 0.0005, \\
\mathcal{B}(B^− \to D^{0}_3 τ(τ)) &= 0.0022 \pm 0.0014, \\
\mathcal{B}(B^− \to D^{0}_4 τ(τ)) &= 0.0048 \pm 0.0008.
\end{align*}
\]

The sum of the \( D^{*+} \) branching fractions satisfies \( \mathcal{B}(B^− \to D^{(*)}_πτ(τ)) \) which implies that the non-resonant branching fractions are small. We use

\[
\begin{align*}
\mathcal{B}^{NR}(B^− \to Dπτ(τ)) &= 0.0015 \pm 0.0015, \\
\mathcal{B}^{NR}(B^− \to D^ππτ(τ)) &= 0.0045 \pm 0.00045.
\end{align*}
\]

From these numbers the branching fraction ratios are calculated and listed in Table II. These quantities are taken as independent when evaluating systematic uncertainties.

\[ f_{D_1}\mathcal{B}_{D_1/D_1} + \frac{B(B^− \to D^0_0 τ(τ))}{B(B^− \to D^0_1 τ(τ))}} + \frac{B(B^− \to D^0_2 τ(τ))}{B(B^− \to D^0_3 τ(τ))} + \frac{B(B^− \to D^0_4 τ(τ))}{B(B^− \to D^0_5 τ(τ))} = \frac{B(B^− \to D^{(*)}_0 πτ(τ))}{B(B^− \to D^{(*)}_πτ(τ)) + B(B^− \to D^{*π}τ(τ))}, \]

V. GLOBAL FIT

The binned distributions of \( D^0\ell \) and \( D^+\ell \) candidates in the variables \( p^*_\ell \), \( p^*_{D} \) and \cosθ_{B−D\ell} \) are fitted with the sum of distributions for the signal and background sources listed in Sec. III.B. The expected shape of the individual components is based on simulation, and the fit adjusts the normalization of each component to minimize the global chi-squared:

\[
χ^2(\alpha) = \sum_{\text{bin } i} \left( \frac{N^\text{on}_{i} - r_{\ell} N^\text{off}_{i} - \sum_{j} r_{j} C_{j} M_{ij}}{\sigma^2_{i}} \right)^2 + \sum_{j} C_{j}^{2}(\sigma^{MC}_{ij})^2, \tag{22}
\]

where the index \( i \) sums over bins of the \( D^0\ell \) and \( D^+\ell \) distributions and \( j \) sums over individual simulated components. The coefficients \( C_{j} \) depend on \( \alpha \), the set of free parameters determined by minimizing \( χ^2 \). For example, for the \( B^− \to D^{0}π\ell \) component the coefficient \( C_{j} \) is given by the ratio of the fitted \( \mathcal{B}(B^− \to D^{0}π\ell) \) branching fraction to the value used in generating the corresponding distribution. The number of candidates in the data collected on (below) the \( Υ(4S) \) peak in bin \( i \) is denoted \( N^\text{on}_{i} \) \( (N^\text{off}_{i}) \) and \( M_{ij} \) is the number of simulated events in bin \( i \) from source \( j \). The \( M_{ij} \) may depend on \( \alpha \) as explained below. The statistical uncertainties, after \( D \) mass side-band subtraction, are given by the \( σ_{j} \) for the data and the \( σ_{ij} \) for the different Monte Carlo samples. The factor \( r_{j} \) is the ratio of the on-peak luminosity to the effective luminosity of the appropriate Monte Carlo sample. Only those bins in which the number of entries expected from the simulation exceeds 10 are used in the \( χ^2 \) sum.

For the \( \overline{B} \to Dπ\ell \) and \( \overline{B} \to D^*π\ell \) signal components we fit for both the branching fractions and for form-factor parameters. To facilitate this, we split these components into sub-components, one corresponding to each unique combination of the parameters \( \alpha \) in the expression for the decay rate. In terms of the notation used in Eq. 22, we set

\[
C_{j} M_{ij} = \sum_{k} C_{j}^{(k)} M_{ij}^{(k)}, \tag{23}
\]

where the index \( k \) runs over the sub-components. For example, the form factor in \( \overline{B} \to Dπ\ell \) decays is of the form \( \mathcal{G}(z, ρ^2_D) = A(z) - ρ^2_D B(z) \), where \( ρ^2_D \), the slope of the form factor, is a parameter in the fit and \( z \) is a kinematic variable. The decay rate, which depends on the square of \( \mathcal{G} \), has terms proportional to 1, \( ρ^2_D \) and \( (ρ^2_D)^2 \), thus requiring three sub-components with coefficients \( C_{j}^{(1)} \) to \( C_{j}^{(3)} \). The calculation of the variance for the \( \overline{B} \to Dπ\ell \) component involves the fourth power of \( \mathcal{G} \) and thus requires five sub-components. For the \( \overline{B} \to D^*π\ell \) decay we use 18 sub-components to allow the fitting of the form factor parameters \( R_1, R_2 \) and \( ρ^2_D \), and 75 sub-components to calculate the associated variance. By breaking the components up in this way the fitted parameters enter only as multiplicative factors on specific...
component histograms, $M_i^{(k)}$, which allows us to use pre-made histograms to re-calculate expected yields, avoids the need to loop over the simulated events at each step in the $\chi^2$ minimization process and results in a dramatic reduction in the required computation time.

### A. Fit parameters and inputs

The semileptonic decay widths of $\mathcal{B} \to D^0 \tau \bar{\tau}$, $\mathcal{B} \to D^* \tau \bar{\tau}$ and $\mathcal{B} \to D^{**} \tau \bar{\tau}$ are required to be equal for $B^+$ and $B^0$. We also require isospin invariance in the decays $D^{**} \to D^{(*)} \pi$. As a result, the $C_j$ depend on the following quantities: $B(B^- \to D^0 \tau \bar{\tau})$ and form factor slope $\rho_D$ for $\mathcal{B} \to D^0 \tau \bar{\tau}$ and $B(B^- \to D^{**} \tau \bar{\tau})$ and form-factor parameters $R_1$, $R_2$ and $\rho_D^2$, for $\mathcal{B} \to D^{(*)} \tau \bar{\tau}$. We fix $R_1$ and $R_2$ to the values obtained in Ref. [9]. The background contributions are kept at the values determined in the simulation. The overall normalizations of the $\mathcal{B} \to D^{(*)} \pi \tau \bar{\tau}$ and $\mathcal{B} \to D^{(*)} \pi \pi \tau \bar{\tau}$ components are also fixed. For the relevant $D$ decay branching fractions we use the values from Ref. [11]. The values of input parameters are listed in Table II, where $f_{D^*_2}$ is defined as the ratio $B(D^*_2 \to D^{0+} \pi^+)/B(D^*_2 \to D^{0+} \pi^{-})$ [11, 26], and $f_{+/-}/f_{00}$ is the ratio of branching fractions $B(T(4S) \to B^\pm B^-)/B(T(4S) \to B^0 \bar{B}^0)$ [11]. All fixed values are varied in assessing systematic uncertainties.

### B. Fit results

The fit is performed separately on the electron and muon samples. The results of these fits are given in Table IV. Both fits give good $\chi^2$ probabilities. The corresponding $\mathcal{B} \to D^\pm \tau \bar{\tau}$ branching fractions are obtained from the $B^- \to B^- \tau \bar{\tau}$ results by dividing by the lifetime ratio [11] $\tau_{B^-}/\tau_{B^0} = 1.071$. The statistical correlations for the electron and muon samples are given in Table V. Fig. 3 and Fig. 4 show the projected distributions on the three kinematic variables for the electron and muon samples along with the ratio of data over fit.

The results of the separate fits to the $D^e$ and $D^\mu$ samples are combined using the full $8 \times 8$ covariance matrix. This matrix is built from a block-diagonal statistical covariance matrix, with one $4 \times 4$ block coming from the fit to each lepton sample, and the full $8 \times 8$ systematic covariance matrix described in Sec. VI. The systematic covariance matrix consists of $4 \times 4$ matrices for the electron and muon parameters and a $4 \times 4$ set of electron-muon covariance terms. The corresponding correlation coefficients are given in Table VI. There is an advantage to combining the electron and muon results after the systematic errors have been evaluated; the results are weighted optimally (e.g., the difference in lepton identification efficiency uncertainties is taken into account) and the $\chi^2$ from the combination provides a valid measure of the compatibility of the electron and muon results. The combined results are given in Table IV, and the correlation coefficients corresponding to the combined statistical and systematic errors are given in Table VII.

### C. Fit validation

The fit was validated in several ways. A large number of simulated experiments were generated based on random samples drawn from the histograms used in the fit. The fit was performed on these simulated experiments to check for biases in the fitted values or associated variances. Small biases in the fitted values of several parameters - in no case exceeding 0.1 standard deviations for both electron and muon samples - were found. Given the smallness of the biases we do not correct the fit results. Additional sets of simulated experiments were generated with alternative values for the parameters. In each case the fit reproduced the alternative values within statistical uncertainties. An independent sample of fully-simulated events was also used to validate the fit.

Additional fits were performed on the data to look for inconsistencies and quantify the impact of additional constraints. The electron and muon samples were combined before fitting; the results were compatible with expectations. Data samples collected in different years were
TABLE IV: Fit results on the electron and muon samples, and their combination. The first error is statistical, the second, systematic.

| $\rho^2_{\rho^*}$ | $0.285 +0.308 +0.283$ | $0.285 +0.308 +0.283$ |

The boundaries of the D mass peak and sideband regions were varied by ±2 MeV/c²; the impact on the fitted parameters was negligible. The minimum number of expected entries per bin was varied from 10 to 100; the impact on the fitted parameters was negligible. Different binning in the variables $p_T^\pi$, $p_T^\rho$ and $\cos\theta_{B-D\ell}$ were tried; the fit results were in each case consistent with the nominal values. The boundaries of the D mass peak and sideband regions were varied by ±2 MeV/c²; the impact on the fitted parameters was negligible.

Additional fits were performed in which $R_1$ and $R_2$ were treated as free parameters. The results, including associated systematic uncertainties, are given in Table VIII. Correlation coefficients for the combined fit are given in Table IX. The three $D^*$ form factor parameters are highly correlated. Comparing this set of parameters with the previous measurement [9], we find they are consistent at the 36% C.L.

VI. SYSTEMATIC STUDIES

There are several sources of systematic uncertainty in this analysis. Table X summarizes the systematic uncertainties on the quantities of interest; these were used in determining the systematic errors and correlations given in Tables IV and VI.

The parameters $R_1$ and $R_2$ are varied taking their correlation ($-0.84$) into account. We transform $R_1$ and $R_2$ into a set of parameters $R_1'$ and $R_2'$ that diagonalize the error matrix, and vary $R_1'$ and $R_2'$ independently. The $D^{**}$ form factor shape is varied in two ways: the slope is varied from $-2.0$ to $-1.0$, and the approximation $B_1$ from Ref. [23] is replaced with $B_2$ (see also Appendix A). The total and relative branching fractions of the $D^{**}$ components in $\overline{B} \to D^{(*)}\pi\pi\pi$ decays are varied independently using the values in Table II. The $D^*/D$ ratio of non-resonant decays, which is defined by $B^{N_R}(B \to D\pi\pi\pi)/B^{N_R}(B \to D\pi\pi)$, is 0.3 in the nominal fit; we vary the ratio from 0.1 to 1.0. The branching fraction of $\overline{B} \to D^{(*)}\pi\pi\pi$ decays is varied as given in Table II, and the production ratios for the states used to model $\overline{B} \to D^{(*)}\pi\pi\pi$ decays, $X^*/X_c, Y^*/Y_c, X_c/Y_c$, and $X^*_c/Y^*_c$, are varied independently from 0.5 to 2.0. To evaluate the effect of $D_1 \to D\pi\pi$ decays [29], one half of the $\overline{B} \to D^{(*)}\pi\pi\pi$ component is replaced by $D_1 \to D\pi\pi$ decays; the differences in fitted values are taken as systematic uncertainties.

The other parameters listed in Table II are also varied within their uncertainties. The determination of the number of $B\overline{B}$ events introduces a normalization uncertainty of 1.1% on the branching fractions. The uncertainty in the luminosity ratio between on-peak and off-peak data is 0.25%.

The $B$ momentum distribution is determined from the well-measured beam energy and $B^0$ mass. The uncertainty of 0.2 MeV in the beam energy measurement leads to a systematic error. Uncertainties arising from the simulation of the detector response to charged particle reconstruction and particle identification are studied by...

TABLE IX: Output correlation coefficients for combined samples with $R_1$ and $R_2$ fitted.

| | $\rho_D^{0}$ | $\rho_D^{\ast}$ | $R_1$ | $R_2$ | $B(D)$ |
|-------|--------------|---------------|------|------|---------|
| $\rho_D^{0}$ | -0.435 | R1 | -0.525 | +0.752 | R2 | +0.519 | -0.787 | -0.740 |
| $R_1$ | | | +0.602 | -0.056 | +0.114 | +0.102 |
| $R_2$ | | | |
| $B(D)$ | +0.310 | +0.406 | +0.139 | -0.309 | +0.212 |

VII. DETERMINATION OF $|V_{cb}|$

The combined fit results with their full covariance matrix are used to calculate $G(1)|V_{cb}|$ and $F(1)|V_{cb}|$:

$$G(1)|V_{cb}| = (43.1 \pm 0.8 \pm 2.3) \times 10^{-3}$$

$$F(1)|V_{cb}| = (35.9 \pm 0.2 \pm 1.2) \times 10^{-3}.$$ (25)

The errors are statistical and systematic, respectively. The associated correlations are $+0.64$ (between $G(1)|V_{cb}|$ and $\rho_D^{0}$), $+0.56$ ($F(1)|V_{cb}|$ and $\rho_D^{\ast}$) and $-0.07$ ($G(1)|V_{cb}|$ and $F(1)|V_{cb}|$).

Using the values of $F(1)|V_{cb}|$ and $G(1)|V_{cb}|$ given above along with calculations of the form factor normalizations allows one to determine $|V_{cb}|$. Using a recent lattice QCD calculation, $G(1) = 1.074 \pm 0.018 \pm 0.016$ [33], multiplied by the electroweak correction [32] of 1.007, we find

$$D^\ast \ell\nu: |V_{cb}| = (39.9 \pm 0.8 \pm 2.2 \pm 0.9) \times 10^{-3}.$$ (27)

where the errors are statistical, systematic and theoretical, respectively.

VIII. DISCUSSION

The branching fractions and slope parameters measured here for $\bar{B} \to D^\ast \ell\nu$ and $\bar{B} \to D \ell\nu$ are consistent with the world averages [25] for these quantities. The measurements of $\rho_D^{0}$ and $G(1)|V_{cb}|$ represent significant improvements on existing knowledge. The experimental technique used here, namely a simultaneous global fit to

\[I = \sum \Delta \alpha_i \Delta \alpha_j.\] (24)
TABLE X: Systematic uncertainties on fitted parameters, given in %. Numbers are negative when the fitted value decreases as input parameter increases.

$B \rightarrow D^0X\pi\pi$ and $\overline{B} \rightarrow D^+X\pi\pi$ combinations, is complementary to previous measurements. In particular, it does not rely on the reconstruction of the soft transition pion from the $D^\ast \rightarrow D\pi$ decay.

The results obtained here, which are given in Table IV, can be combined with the existing $B\overline{B}$ measurements listed in Table XI. For $B \rightarrow D^\ast\pi\pi$, we combine the present results with two $B\overline{B}$ measurements of $\rho_D^{2\ast}$, and $\mathcal{F}(1)|V_{cb}|$ [9, 10] and four measurements of $B(B^- \rightarrow D^{\ast\ast}\pi)$ [6, 9, 10]. We neglect the tiny statistical correlations among the measurements and treat the systematic uncertainties as fully correlated within a given category (background, detector modeling, etc.). We assume the semi leptonic decay widths of $B^+$ and $B^0$ to be equal and adjust all measurements to the values of the $\mathcal{F}(4S)$ and $D$ decay branching fractions used in this article to obtain

$$B(B^- \rightarrow D^{\ast0}\pi\pi) = (5.49 \pm 0.19)\%$$

(31)

$$\rho_D^{2\ast} = 1.20 \pm 0.04$$

(32)

$$\mathcal{F}(1)|V_{cb}| = (34.8 \pm 0.8) \times 10^{-3}.$$ 

(33)

The associated $\chi^2$ probabilities of the averages are 0.39, 0.86 and 0.27, respectively. The average of the $B(B^- \rightarrow D\pi\pi)$ result with the two existing $B\overline{B}$ measurements [6] is

$$B(B^- \rightarrow D^0\ell\pi) = (2.32 \pm 0.09)\%$$

(34)

with a $\chi^2$ probability of 0.88.

The simultaneous measurements of $\mathcal{G}(1)|V_{cb}|$ and $\mathcal{F}(1)|V_{cb}|$ allow a determination of the ratio $\mathcal{G}(1)/\mathcal{F}(1)$ which can be compared directly with theory. We find

Measured : $\mathcal{G}(1)/\mathcal{F}(1) = 1.20 \pm 0.09$

(35)

Theory : $\mathcal{G}(1)/\mathcal{F}(1) = 1.17 \pm 0.04$. 

(36)
where we have assumed the theory errors on \( F(1) \) [31] and \( G(1) \) [33] to be independent. The measured ratio is consistent with the predicted ratio.

The excellent description obtained in this fit, at the 1% statistical level, of the dominant Cabibbo-favored semileptonic decays will facilitate the determination of decay rates of Cabibbo-suppressed decays over a larger kinematic region than has been feasible to date. This will result in a reduction in the theoretical uncertainty on the determination of \(|V_{cb}|\).

To summarize: we use a global fit to \( D^0 \ell \) and \( D^+ \ell \) combinations to measure the form factor parameters

\[
\rho^2_D = 1.20 \pm 0.04 \pm 0.07 \\
\rho^2_{D^*} = 1.22 \pm 0.02 \pm 0.07 ,
\]

in the commonly used HQET-based parameterization [16] and the branching fractions

\[
B(B^- \rightarrow D^0 \ell \nu) = (2.34 \pm 0.03 \pm 0.13)\% \\
B(B^- \rightarrow D^{*0} \ell \nu) = (5.40 \pm 0.02 \pm 0.21)\% ,
\]

where the first error is statistical and the second systematic. The fit assumes the semileptonic decay widths of \( B^+ \) and \( B^0 \) to be equal. These results are consistent with previous \( \bar{B}\bar{B}\bar{B} \) measurements [6, 9, 10]. From these slopes and branching fractions we determine

\[
G(1)|V_{cb}| = (43.1 \pm 0.8 \pm 2.3) \times 10^{-3} \\
F(1)|V_{cb}| = (35.9 \pm 0.2 \pm 1.2) \times 10^{-3} .
\]

The \( G(1)|V_{cb}| \) value is twice as precise as the current world average. The precision on \( F(1)|V_{cb}| \) equals that of the best single measurement, while coming from a complementary technique. From these results, we extract two values for \( |V_{cb}| \):

\[
D^* \ell \nu : |V_{cb}| = (38.6 \pm 0.2 \pm 1.3 \pm 1.0) \times 10^{-3} \\
D \ell \nu : |V_{cb}| = (39.9 \pm 0.8 \pm 2.2 \pm 0.9) \times 10^{-3} ,
\]

where the errors correspond to statistical, systematic and theoretical uncertainties, respectively.

### IX. ACKNOWLEDGEMENTS

We are grateful for the extraordinary contributions of our PEP-II colleagues in achieving the excellent luminosity and machine conditions that have made this work possible. The success of this project also relies critically on the expertise and dedication of the computing organizations that support \( \bar{B}\bar{B}\bar{B} \). The collaborating institutions wish to thank SLAC for its support and the kind hospitality extended to them. This work is supported by the US Department of Energy and National Science Foundation, the Natural Sciences and Engineering Research Council (Canada), the Commissariat à l’Energie Atomique and Institut National de Physique Nucléaire et de Physique des Particules (France), the Bundesministerium für Bildung und Forschung and Deutsche Forschungsgemeinschaft (Germany), the Istituto Nazionale di Fisica Nucleare (Italy), the Foundation for Fundamental Research on Matter (The Netherlands), the Research Council of Norway, the Ministry of Education and Science of the Russian Federation, Ministerio de Educación y Ciencia (Spain), and the Science and Technology Facilities Council (United Kingdom). Individuals have received support from the Marie-Curie IEF program (European Union) and the A. P. Sloan Foundation.

The rest frame of the virtual W boson is used in assessing systematic errors. Uncertainty in first order expansion of Isgur-Wise function is assumed to be a linear form [23]

\[ \tau(w) = \tau(1)[1 + \tau'(w-1)]. \]  

(A7)

Uncertainty in first order expansion of Isgur-Wise function is parameterized in \( \tau_1 \) and \( \tau_2 \). In approximation \( B_1 \) one sets

\[ \tau_1 = 0, \quad \tau_2 = 0, \]  

(A8)

APPENDIX A: MODELING OF \( \bar{B} \rightarrow D^{**}\ell\nu_\ell \) DECAYS

The differential decay rates of \( \bar{B} \rightarrow D^{**}\ell\nu_\ell \) decays are given as functions of \( w \) and \( \theta \) [23]. This \( \theta \) is the angle between the charged lepton and the charmed meson in the rest frame of the virtual W boson. Thus \( \theta \) is related to \( \theta_\ell \), which is defined in Fig. 5, such that

\[ \cos \theta = \cos(\pi - \theta_\ell) = -\cos \theta_\ell. \]  

(A1)
while in approximation B₂ one takes
\[ \tau_1 = \bar{\tau} \tau, \quad \tau_2 = -\bar{\tau}' \tau. \] (A9)

b. \( \bar{B} \to D'_2 \ell \bar{\nu} \)

The differential decay rate is given by
\[ \frac{d^2 \Gamma_{D_2}}{dw d\cos \theta} = \Gamma \varepsilon r^3 (w^2 - 1)^{3/2} \frac{1}{2} \mathcal{I}_{D_2}(w, \theta), \] (A10)

where
\[ \mathcal{I}_{D_2}(w, \theta) = \frac{4}{3} \left( 1 - \cos^2 \theta \right) \left[ (w - r) k_{A_1} + (w^2 - 1) (k_{A_3} + r k_{A_2}) \right]^2 \\
+ (1 - 2 r w + r^2) (1 + \cos^2 \theta) \left( k_{A_1}^2 + (w^2 - 1) k_{A_2}^2 \right) \\
- 4 \cos \theta \sqrt{w^2 - 1} k_{A_1} k_{V}. \] (A11)

and \( k_V(w), k_{A_1}(w), k_{A_2}(w) \) and \( k_{A_3}(w) \) are form factors which are given by
\[ k_V = -\tau - \varepsilon_b [ (\bar{\Lambda}' + \bar{\Lambda}) \tau - (2w + 1) \tau_1 - \tau_2 ] \]
\[ -\varepsilon_c (\tau_1 - \tau_2) \]
\[ k_{A_1} = -\left( 1 + w \right) \tau \]
\[ -\varepsilon_b (w - 1) [ (\bar{\Lambda}' + \bar{\Lambda}) \tau - (2w + 1) \tau_1 - \tau_2 ] \]
\[ -\varepsilon_c (w - 1) (\tau_1 - \tau_2) \] (A12)
\[ k_{A_2} = -2 \varepsilon_c \tau_1 \]
\[ k_{A_3} = \tau + \varepsilon_b [ (\bar{\Lambda}' + \bar{\Lambda}) \tau - (2w + 1) \tau_1 - \tau_2 ] \]
\[ -\varepsilon_c (\tau_1 + \tau_2). \]

c. \( \bar{B} \to D'_0 \ell \bar{\nu} \)

The differential decay rate is given by
\[ \frac{d^2 \Gamma_{D'_0}}{dw d\cos \theta} = \Gamma \varepsilon r^3 (w^2 - 1)^{3/2} \mathcal{I}_{D'_0}(w, \theta), \] (A13)

where
\[ \mathcal{I}_{D'_0}(w, \theta) = (1 - \cos^2 \theta) [ (1 + r) g_+ - (1 - r) g_- ]^2 \] (A14)

and \( g_+(w) \) and \( g_-(w) \) are form factors which are given by
\[ g_+ = \varepsilon_c \left[ 2 (w - 1) \zeta_1 - 3 \varepsilon \frac{w \bar{\Lambda}' - \bar{\Lambda}}{w + 1} \right] \\
-\varepsilon_b \left[ (w \bar{\Lambda}' - \bar{\Lambda}) \zeta - 2(w - 1) \zeta_1 \right] \] (A15)

with
\[ \zeta(w) = \frac{w + 1}{\sqrt{3}} \tau(w). \] (A16)

In approximation B₁ one uses
\[ \zeta_1 = 0, \quad \zeta_2 = 0, \] (A17)

while in approximation B₂ one takes
\[ \zeta_1 = \bar{\zeta}, \quad \zeta_2 = -\bar{\Lambda}' \zeta. \] (A18)

d. \( \bar{B} \to D'_2 \ell \bar{\nu} \)

The differential decay rate is given by
\[ \frac{d^2 \Gamma_{D'_2}}{dw d\cos \theta} = \Gamma \varepsilon r^3 (w^2 - 1)^{1/2} \mathcal{I}_{D'_2}(w, \theta), \] (A19)

where
\[ \mathcal{I}_{D'_2}(w, \theta) = (1 - \cos^2 \theta) [ (w - r) g_{V_1} + (w^2 - 1) (g_{V_3} + r g_{V_2}) ]^2 \\
+ (1 - 2 r w + r^2) (1 + \cos^2 \theta) [ (w^2 - 1) g_{V_1}^2 + (w^2 - 1) g_{A}^2 ] \\
- 4 \cos \theta \sqrt{w^2 - 1} g_{V_1} g_A \] (A20)

and \( g_{V_1}(w), g_{V_3}(w), g_{V_2}(w) \) and \( g_A(w) \) are form factors which are given by
\[ g_A = \zeta + \varepsilon_c \left[ \frac{w \bar{\Lambda}' - \bar{\Lambda}}{w + 1} \right] \]
\[ -\varepsilon_b \left[ \frac{w \bar{\Lambda}' - \bar{\Lambda}}{w + 1} \right] \zeta - 2(w - 1) \zeta_1 \]
\[ g_{V_1} = (w - 1) \zeta + \varepsilon_c \left[ w \bar{\Lambda}' - \bar{\Lambda} \right] \zeta \]
\[ -\varepsilon_b \left[ (w \bar{\Lambda}' - \bar{\Lambda}) \zeta - 2(w - 1) \zeta_1 \right] \]
\[ g_{V_2} = 2 \varepsilon_c \zeta_1 \]
\[ g_{V_3} = -\zeta - \varepsilon_c \left[ \frac{w \bar{\Lambda}' - \bar{\Lambda}}{w + 1} \right] \zeta + 2 \zeta_1 \]
\[ +\varepsilon_b \left[ \frac{w \bar{\Lambda}' - \bar{\Lambda}}{w + 1} \right] \zeta - 2(w - 1) \zeta_1. \] (A21)
