Abstract

Using Clifford and Spin-Clifford formalisms we prove that the classical relativistic Hamilton Jacobi equation for a charged massive (and spinning) particle interacting with an external electromagnetic field is equivalent to Dirac-Hestenes equation satisfied by a class of spinor fields that we call classical spinor fields. These spinor fields are characterized by having the Takabayashi angle function constant (equal to 0 or π). We also investigate a nonlinear Dirac-Hestenes like equation that comes from a class of generalized classical spinor fields. Finally, we show that a general Dirac-Hestenes equation (which is a representative in the Clifford bundle of the usual Dirac equation) gives a generalized Hamilton-Jacobi equation where the quantum potential satisfies a severe constraint and the “mass of the particle” becomes a variable. Our results can then eventually explain experimental discrepancies found between prediction for the de Broglie-Bohm theory and recent experiments. We briefly discuss de Broglie's double solution theory in view of our results showing that it can be realized, at least in the case of spinning free particles. The paper contains several Appendices where notation and proofs of some results of the text are presented.

1 Introduction

In this paper we prove that the relativistic Hamilton-Jacobi equation for a massive particle charged particle moving in Minkowski spacetime and interacting with an electromagnetic field is equivalent to Dirac equation satisfied by a special class of Dirac spinor fields\(^1\) (characterized by having the Takabayashi angle

\(^1\)This special class of spinor fields will be called classical spinor fields.
function equal to 0 or \(\pi\). Also, any Dirac equation satisfied by these classical spinor fields implies in a corresponding relativistic Hamilton-Jacobi equation.

After proving these result we show that since general spinor fields which are solutions of the Dirac equation in an external potential have in general Takabayashi angle functions \([1, 6]\) which are not constant like 0 or \(\pi\). Thus, the corresponding derived generalized Hamilton-Jacobi equation (GHJE) besides having a quantum potential which must satisfy a very severe constraint (see Eq. (30)) has also a variable mass (which is a function of the Takabayashi angle function). So, the usual equations derived from Schrödinger equation used in simulations of, e.g., the double slit experiments, do not take into account that the mass of the particle, which comes from the generalized HJE becomes a variable. This eventually must explain discrepancies found between theoretical predictions from the de Broglie and Bohm formalism \([7, 2, 22]\) and some results of experiments and inconsistencies (such as necessity of surreal trajectories) as related, e.g., in \([3, 4, 10, 23, 27, 36]\). We briefly discuss also the de Broglie’s double solution theory in view of our results, finding that, at least for the case of a free (spinning particle) it can be realized.

To show the above results we will use Clifford bundle formalism where Dirac spinor fields are represented by an equivalence class of even sections of the Clifford bundle \(\mathcal{C}(M, \eta)\) of differential forms. Details about this theory and notation used may be found in \([32, 31, 34]\) and a resume is given in the Appendix. Here we recall that in this paper all calculations are done in the Minkowski spacetime \((M \simeq \mathbb{R}^4, \eta, D, \tau, \uparrow)\).

2 A Trivial Derivation of the Relativistic Hamilton-Jacobi Equation (HJE)

Let \(\sigma : \mathbb{R} \to M, s \mapsto \sigma(s)\) be a timelike curve in spacetime time representing the motion of a particle of mass \(m\) and electrical charge \(e\) interacting with an electromagnetic field \(F = dA\), where the potential \(A \in \sec \bigwedge^1 T^* M \hookrightarrow \sec \mathcal{C}(M, \eta)\) and \(F \in \sec \bigwedge^2 T^* M \hookrightarrow \sec \mathcal{C}(M, \eta)\). Let \(\sigma_*\) be the velocity of the particle and define

\[
v = \eta(\sigma_*, \sigma) \tag{1}\]

as a 1-form field over \(\sigma\). Then, the motion of such particle, as is well known is governed in classical electrodynamics by the Lorentz force law, i.e.,

\[
m\dot{v} = ev \wedge F. \tag{2}\]

where \(\dot{v} = dv/ds\) Now, let \(V \in \sec \bigwedge^1 T^* M \hookrightarrow \sec \mathcal{C}(M, \eta)\) be a vector field such that

\[
V|_\sigma = v, \quad V^2 = 1. \tag{3}\]

\(^2\)Notice that \(\eta\) is a mapping from \(TM \times TM\) to \(\mathbb{F}\), the set of real functions. So, it defines a mapping \(\sec TM \ni X \mapsto \eta(X, \cdot) = X \in \sec T^* M\).
As defined in the Appendix, let \( \{ x^\mu \} \) be global coordinates for \( M \) in Einstein-Lorentz-Poincaré gauge, let \( \{ \gamma^\mu \} \in \sec \wedge^1 T^* M \leftrightarrow \sec \mathcal{C} \ell(M, \eta) \). In these coordinates, the Dirac operator \( \partial \) and the representative of the spin-Clifford operator \( \partial(s) \) acting on a representative \( \psi \in \sec \mathcal{C} \ell(M, \eta) \) of Dirac-Hestenes spinor field \( \Psi \in P^{\text{Spin}01}_3(M, \eta) \times_\rho \mathbb{C}^4 \) in a given spin frame \( \Xi \in \sec P^{\text{Spin}01}_3(M, g) \) are both represented by \( \gamma^\mu \partial_\mu \), i.e.,

\[
\partial = \gamma^\mu \partial_\mu, \quad \partial(s) = \gamma^\mu \partial_\mu.
\]

(4)

Now, we can show the following identity\(^3\):

\[
\dot{\psi} = V \langle \partial V \rangle_\sigma = V \langle \partial \wedge V \rangle_\sigma = V \langle dV \rangle_\sigma
\]

(5)

and thus we can write Eq. (2) as

\[
V \langle d(mV - eA) \rangle_\sigma = 0.
\]

(6)

In what follows we suppose that Eq. (6) holds for each integral line of the vector field \( \mathbf{V} = \eta(\mathbf{V}, \ ) \), i.e.,

\[
V \langle d(mV - eA) \rangle = 0.
\]

(7)

A sufficient condition for the validity of Eq. (7) is, of course the existence of a scalar function \( S \) such that

\[
mV - eA = -dS = -\partial S.
\]

(8)

We immediately recognize \( \Pi := -\partial S \) as the canonical momentum and of course taking into account that \( V^2 = 1 \) we get from Eq. (8) that

\[
(\Pi + eA)^2 = m^2
\]

(9)

which is the relativistic Hamilton Jacobi equation \([24]\).

### 3 A Classical Dirac-Hestenes Equation

To proceed, we recall that it is always possible to choose a gauge for the potential such that the components \( \Pi_\mu \) of the canonical momentum are constant. We suppose in what follows that the potentials are already in this gauge. Moreover, we recall that an invertible representative \( \psi \) (in the Clifford bundle) of Dirac-Hestenes spinor field can be written as\(^5\)

\[
\psi = \rho^{1/2} e^{\frac{\Pi}{2m}} \mathbf{R} \in \sec(\wedge^0 T^* M + \wedge^2 T^* M + \wedge^4 T^* M) \leftrightarrow \sec \mathcal{C} \ell(M, \eta)
\]

(10)

\(^3\)Thus the 1-forms \( \gamma^\mu \) satisfy \( \gamma^\mu \gamma^\nu + \gamma^\nu \gamma^\mu = 2\eta^\mu\nu \).

\(^4\)Observe that identity given by Eq. (5) is also valid in a general Lorentzian manifold.

\(^5\)Recall that \( \gamma^5 = \tau_0 \in \sec \wedge^4 T^* M \leftrightarrow \sec \mathcal{C} \ell(M, g) \) is the volume element 4-form field.
where $\rho, \beta \in \sec \wedge^0 \mathcal{T}^* M$ and for each $x \in M$, $R(x) \in \text{Spin}^0_{1,3} \cong \text{Sl}(2, \mathbb{C})$ and $RR^{-1} = R^{-1}R = 1$ and $R = \tilde{R}$ is called a rotor. Of course, $\psi^{-1} = R^{-1} \rho^{-1/2} e^{-\frac{i}{2} \beta}$.

Next, we choose $\psi$ such that
\[ V = \psi \gamma^0 \psi^{-1} = e^{\gamma_5 \beta} R \gamma^0 R^{-1}. \] (11)

Since $V \in \sec \wedge^1 \mathcal{T}^* M \hookrightarrow \sec \text{Cl}(M, \eta)$, necessarily the Takabayashi angle $\beta$ must be $0$ or $\pi$. As we said in the introduction we will call spinor fields satisfying this condition classical spinor fields. We now write $R = R(\Pi) e^{S_\gamma 21}$ where for each $x \in M$, $R(\Pi) \in \text{Spin}^0_{1,3}$ is a rotor depending on $\Pi$ (see Eq. (20) below). We then return to Eq. (8) and multiply it on the right with $\psi$ getting
\[ \Pi \psi = -\partial S \psi = m \psi \gamma^0 - eA \psi = 0. \] (12)

We now ask: is it possible to define a differential operator $\hat{\Pi}$ acting on sections of the Clifford bundle such that
\[ \hat{\Pi} \psi = \Pi \psi. \] (13)

The answer is yes if we define
\[ \hat{\Pi} \psi = \partial \psi \gamma^{21} \] (14)

and use the particular classical spinor field
\[ \psi = R(\Pi)e^{S_\gamma 21}. \] (15)

Indeed, in this case it is
\[ \partial \psi \gamma^{21} = -\partial S \psi = \Pi \psi. \] (16)

So, the classical spinor field given by Eq. (15) satisfies the first order partial differential equation
\[ \partial \psi \gamma^{21} - m \psi \gamma^0 + eA \psi = 0. \] (17)

**Remark 1** Eq. (17) for a general Dirac-Hestenes spinor field is known as the Dirac-Hestenes equation [15] which is a representative in the Clifford bundle (see Appendix C) of the traditional Dirac equation for a covariant Dirac spinor field $\Psi \in \sec P_{\text{Spin}^0_{1,3}}(M, \eta) \times_\rho \mathbb{C}^4$ which read in a chart for $M$ with coordinates in Einstein-Lorentz-Poincaré gauge:
\[ i\gamma^\mu (\partial_\mu - ieA_\mu) \Psi + m \Psi = 0. \] (18)

---

6 Notice that we are using a natural system of units where the numerical values of Planck constant $\hbar$ and the speed of light $c$ are equal to one.

7 In Eq. (13), the $\gamma^\mu$, are Dirac matrices in standard representation.
So, we have proved that there is a class of classical spinor fields (the ones satisfying \( \text{Eq. (15)} \)) such that the relativistic Hamilton-Jacobi equation is equivalent to the celebrated Dirac equation. Of course, it is a trivial exercise to show that starting from \( \text{Eq. (17)} \) for a spinor field satisfying \( \text{Eq. (15)} \) we get the relativistic Hamilton-Jacobi equation.

So, to complete this section we need to determine the rotor \( R(\Pi) \). Note that we must have

\[
\Pi + eA = mV = mR\gamma^0 R^{-1}
\]

and then as shown in Appendix C we find

\[
R(\Pi) = \frac{m + (\Pi + eA)\gamma^0}{2(m + \Pi_0 + eA_0)^{1/2}}.
\]

### 4 A Classical Non Linear Dirac-Hestenes Equation

Note that supposing the validity of the classical HJE if instead of taking \( \psi \) as in \( \text{Eq. (15)} \) we write

\[
\psi = \theta^{1/2} R(\Pi)e^{S\gamma^{21}} = \psi_0 e^{S\gamma^{21}},
\]

we get

\[
\partial \psi \gamma^{21} = (\partial \ln \psi_0)\psi \gamma^{21} - \partial S \psi.
\]

Thus, substituting this result in \( \text{Eq. (12)} \) we get a **nonlinear** Dirac-Hestenes equation \[34\], namely

\[
\partial \psi \gamma^{21} = -m\psi \gamma^0 + eA\psi - (\partial \ln \psi_0)\psi \gamma^{21}.
\]

**Remark 2** Notice that in this case \( \partial \ln \psi_0 = \frac{1}{2} \partial \ln \rho \).

### 5 The GHJE which Follows from the General Dirac Equation

In this section we start from the Dirac-Hestenes equation satisfied by a general Dirac-Hestenes spinor field whose representative in the Clifford bundle in a given spin frame is written as

\[
\psi = \rho^{1/2} R(\Pi)e^{\tilde{\alpha}\gamma^5} e^{S\gamma^{21}} = \psi_0 e^{\tilde{\alpha}\gamma^5} e^{S\gamma^{21}} = e^{\tilde{\alpha}\gamma^5} \psi_0 e^{S\gamma^{21}}.
\]

Thus we have

\[
\partial \psi \gamma^{21} = (\partial \ln \psi_0)\psi \gamma^{21} - \partial S \psi - \frac{1}{2} \gamma^5 \partial (\ln \beta) \psi
\]
and the Dirac-Hestenes equation becomes

\[(\partial \ln \psi_0)\psi \gamma^{21} - \partial S \psi - \frac{1}{2} \gamma^5 \partial (\ln \beta) \psi - m \psi \gamma^0 + e A \psi = 0. \tag{26}\]

Multiplying Eq. (26) on the right by \(\psi^{-1}\) and identifying \(\Pi = -\partial S\) we get

\[\psi \gamma^0 \psi^{-1} = e \beta \gamma^5 V\] \(\tag{27}\)

that

\[\Pi = m e^\beta \gamma^5 V + e A + (\partial \ln \psi_0) \psi \gamma^{21} \psi^{-1} + \frac{1}{2} \gamma^5 \partial (\ln \beta) \psi, \tag{28}\]

which can be written as

\[\Pi = m \cos \beta V + e A + (\partial \ln \psi_0) \psi \gamma^{21} \psi^{-1} + \frac{1}{2} \gamma^5 \partial (\ln \beta) \psi. \tag{29}\]

Taking into account that \(\Pi = -\partial S\) is a 1-form field, we must necessarily have, for consistency, the following constraint for any solution that implies a genuine classical like equation of motion:

\[\langle m \sin \beta \gamma^5 V + (\partial \ln \psi_0) \psi \gamma^{21} \psi^{-1} + \frac{1}{2} \gamma^5 \partial (\ln \beta) \psi \rangle_3 = 0 \tag{30}\]

If the constraint given by Eq. (30) is satisfied then the classical like equation of motion for the particle is the following generalized Hamilton-Jacobi equation

\[- \partial S = m \cos \beta V + e A + m \sin \beta \gamma^5 V + (\partial \ln \psi_0) \psi \gamma^{21} \psi^{-1} + \frac{1}{2} \gamma^5 \partial (\ln \beta) \psi. \tag{31}\]

Remark 3 The true “quantum potential” is then

\[Q = \langle (\partial \ln \psi_0) \psi \gamma^{21} \psi^{-1} + \frac{1}{2} \gamma^5 \partial (\ln \beta) \psi \rangle_1 \tag{32}\]

which differs considerably from the usual Bohm quantum potential. Moreover and contrary to the usual presentations of the de Broglie-Bohm theory the mass parameter of the particle in the generalized Hamilton-Jacobi equation (Eq. (31)) is not a constant. Instead, it is

\[m' = m \cos \beta. \tag{33}\]

Some results analogous to the ones above but involving classical like equations of motion instead of the generalized Hamilton Jacobi equation (Eq. (31)) have been obtained by Hestenes in memorable papers \[16, 17, 18\].

6 Description of the Spin

In the past sections we associated to a massive and charged particle a Dirac-Hestenes spinor field satisfying Dirac equation which has been shown to be
equivalent to the relativistic HJE. We next show [33, 34] how to describe with
the same classical spinor field the intrinsic spin of the particle. In order to
do that it is necessary to have in mind the concepts of Fermi derivative and
the Frenet formalism. For the reader’s convenience these concepts are briefly
recalled in Appendix C.

As in previous sections, the arena for the motion of particles is Minkowski
spacetime \((M \simeq \mathbb{R}^4, \eta, D, \tau, \uparrow)\) for which there are global tetrad frames. So,
let \(\{e_a\} \in \text{sec} P_{\text{SOe}1,3}(M)\) be one of these global tetrad frames. Let \(\{\gamma^a\}, \gamma^a \in \text{sec} \bigwedge^1 T^* M \hookrightarrow \text{sec} \mathcal{C}l(M, g)\) be the dual frame of \(\{e_a\}\). Also, let \(\{\gamma_a\}\) be the
reciprocal frame of \(\{\gamma_a\}\), i.e., \(\gamma_a \cdot \gamma_b = \delta_a^b\). Suppose moreover that the
reference frame defined by \(e_0\) is in free fall, i.e., \(D e_0 e_0 = 0\) and that the spatial axes along
each one of the integral lines of \(e_0\) have been constructed by Fermi transport
of spinning gyroscopes. This is translated by the requirement that
\(D e_0 e_i = 0\), \(i = 1, 2, 3\), and we have, equivalently \(D e_0 \gamma^a = 0\). We introduce a spin coframe \(\Xi \in P_{\text{Spin1,3}}(M)\) such that
\(s(\pm \Xi) = \{\gamma^a\}\). Now, let \(\Psi\) be the representative
of an invertible Dirac-Hestenes spinor field over \(\sigma\) (the world line of a spinning
particle) in the spin coframe \(\Xi\). Let moreover \(\{f_a\}\) be Frenet coframe over \(\sigma\) such
that \(f_0\) satisfies \(g(f_0, \cdot) = \sigma_*\). Then, since the general form of a representative
of an invertible Dirac-Hestenes over \(\sigma\) is \(\Psi = \rho \frac{1}{2} e^{\frac{\kappa_2}{2} f_2 f_1} R\) we can write for \(\beta = 0\),
\(\pi\)
\(f_a = \Psi \gamma_a \Psi^{-1}. \quad (34)\)
Recalling Eq. (92) from Appendix D, we obtain using Eq. (34) that
\(\frac{1}{2} \Omega_D R, \quad (35)\)
which may be called a spinor equation of motion of a classical spinning particle.

Now, let us show that the spinor equation of motion for a free particle is
equivalent to the classical Dirac-Hestenes equation.

We observe that in this case, of course \(\Omega_D = \Omega_S\). Moreover, we can trivially
redefine the Frenet frame in such a way as to have \(\kappa_3 = 0\). Indeed, this can be
done by rotating the original frame with \(U = e^{i f_3 f_2} \frac{\alpha}{\kappa_1}\) and choosing \(\alpha = \arctan \left(\frac{-\kappa_2}{\kappa_1}\right)\). So, in what follows we suppose that this choice has already been
made. We are interested in the case where \(\kappa_2\) is a real constant. Then, Eq. (35)
becomes
\(\frac{1}{2} \kappa_2 f_2 f_1 R, \quad (36)\)
The solution of Eq. (36) is
\(R = R_0 \exp(\kappa_2 \frac{1}{2} \gamma_2 \frac{1}{2} \gamma_1 t), \quad (37)\)

---

8In Relativity theory a general reference frame in a general Lorentzian spacetime \((M \simeq \mathbb{R}^4, g, D, \tau, \uparrow)\) is a time vector field \(Z\) pointing to the future and such that \(g(Z, Z) = 1\). In
[34] the reader may find a classification of reference frames in Lorentzian spacetimes. For a
preliminary classification of reference frames in Riemann-Cartan spacetimes see [14].

9Details are in [34].

7
where $R_0$ is a constant rotor.

To continue we observe that without any loss of generality we can choose a global tetrad field such that $\gamma^a = \delta^a_\mu dx^\mu$ (where $\{x^\mu\}$ are coordinates in Einstein-Lorentz-Poincaré gauge).

This choice being made we suppose next existence of a covector field $V \in \text{sec} \wedge^1 T^*M \hookrightarrow \text{sec} \mathcal{C}l(M, g)$ and a classical Dirac-Hestenes spinor field with representative $\psi \in \text{sec} \mathcal{C}l(M, \eta)$ in the spin coframe $\Xi$ such that $V|_\sigma = v$ with

$$V|_\sigma = \psi\gamma^0\psi^{-1}|_\sigma = R\gamma^0R^{-1}.$$  

Then, under all these conditions, writing

$$\psi = \psi_0(p)e^{\gamma_21px}$$  

$$p = \frac{\kappa_2}{2}v$$  

and $x = x^\mu \gamma^\mu$, we can rewrite Eq. (39), identifying $\psi_0(p)|_\sigma = R_0$ as:

$$D_{e_0}R = \gamma^0 \cdot \partial \psi = \frac{1}{2}\kappa_2v^0\psi\gamma^{21}.$$  

which reduces to Eq. (36) in a reference frame $e_0$ such that $e_0|_\sigma = v$.

Putting $m = -\frac{2\kappa_2}{\kappa_2}$ we immediately obtain

$$\partial\psi\gamma^2\gamma^1 - m\psi\gamma^0 = 0.$$  

the classical Dirac-Hestenes equation. Note that the signal of $\kappa_2$ merely defines the sense of rotation in the $e_2 \wedge e_1$ plane.

The bilinear invariant $\Omega_S \in \text{sec} \wedge^2 T^*M \hookrightarrow \mathcal{C}l(M, g)$

$$\Omega_S = k\psi\gamma^2\gamma^1\tilde{\psi}$$  

is the spin biform field. Note that for our example $S = \ast \Omega_S \hookrightarrow \mathcal{C}l(M, g)$ and so it may be called the spin covector field.

The classical spinor equation for an electrical spinning particle interacting with an external electromagnetic field can be easily obtained using the principle of minimal coupling. We find that $p$ must be substituted by the canonical momentum and we arrive at Eq. (17).

Remark 4 The results just obtained show that a natural interpretation suggests itself for the plane ‘wave function’ $\psi$ in the theory just presented. It describes a kind of “probability” field in the sense that it describes a whole set of possible particle trajectories which are non determined, as it is the case in Hamilton-Jacobi theory, unless appropriate initial conditions for position and momentum are given (something we know is prohibit by Heisenberg uncertainty principle). Thus, it is, not a physical field in any sense. This last observation agrees with de Broglie opinion in [7] which he uses to develop his theory of the double solution. We will now show how de Broglie’s idea can be realized in our theory.
7 Realization of De Broglie’s Idea of the Double Solution

In this section we will examine only the case of a free particle. We recall that de Broglie [7] tried hard to constructed a theory where the Dirac-Hestenes for a free particle equation besides having the $\psi = R(p)e^{S\gamma^2}$ [10] with statistical significance also possesses a “singular” solution of the form

$$F (x) = F_0(x)e^{S(x)\gamma^2}$$ (44)

where $F$ is the representative in the Clifford Bundle of a real (not fictitious) classical Dirac-Hestenes spinor field describing the motion of a singularity. De Broglie thought that $F_0(x)$ must solve a nonlinear equation. However, this is not the case. We show now that if $F$ satisfies the Dirac-Hestenes equation then $F_0(x)$ satisfies the massless Dirac-Hestenes equation, i.e.,

$$\partial F_0 = 0.$$ (45)

Indeed, let us calculate $\partial F (x)$. We have

$$\partial F = (\partial F_0)e^{S\gamma^2} + \partial S F_0 e^{S\gamma^2} \gamma^{21}$$ (46)

But

$$- \partial S = P = mV = mF_0\gamma^0 F^{-1}_0.$$ (47)

Using this result in Eq. (46)

$$\partial F = (\partial F_0)e^{S\gamma^2} - mVF_0 e^{S\gamma^2} \gamma^{21}$$ (48)

$$\partial F \gamma^{21} = (\partial F_0)e^{S\gamma^2} \gamma^{21} + mF \gamma^0$$ (49)

and since $F$ satisfies the Dirac-Hestenes equation we have that $\partial F_0 = 0$

The question that immediately comes to mind is:

May Eq. (45) possess solutions satisfying the constraint (47) describing the motion of a massive (and spinning) free particle moving with a subluminal velocity $v$?

The answer to that question is yes. Indeed, introducing the potential $A \in \text{sec} \bigwedge T^*M \hookrightarrow \text{sec} \mathcal{O}(M, g)$ and defining

$$F_0 := \partial A$$ (50)

we have immediately from Eq. (45) that

$$\partial^2 A = 0.$$ (51)

Of course, de Broglie used the standard matrix formulation for the Dirac equation since the idea of Dirac-Hestenes spinor fields where not known when he was investigating his theory the double solution.
Now, we found in [29, 30] that Eq. (51) has subluminal soliton like solutions. Putting $x^0 = t$, $x^1 = x$, $x^2 = y$, $x^3 = z$ and supposing for simplicity that the wave is moving in the $z$-direction, a subluminal solution rigidly moving with velocity (1-form) $v$ is

$$A = C \frac{\sin m \xi}{\xi} \sin(\omega t - k z) \gamma^1.$$  \hspace{1cm} (52)

with

$$\xi = \left[ (x)^2 + (y)^2 + \Gamma^2(z - vt)^2 \right]^\frac{1}{2},$$

$$\Gamma = (1 - v^2)^{-\frac{1}{2}},$$

$$\omega^2 - k^2 = m^2,$$

$$0 < v = \frac{d\omega}{dk} < 1.$$

and where $C$ is a constant. Then, the moving soliton like object realizing de Broglie dream is

$$F_0 = C \partial \left( \frac{\sin m \xi}{\xi} \cos(\omega t - k z) \right) \gamma^1.$$  \hspace{1cm} (53)

Observe that in the rest frame of the soliton $F_0 \in \text{sec} \bigwedge^2 T^*M \hookrightarrow \text{sec} \mathcal{C} \ell(M, g)$ is simply

$$F_0 = C \partial \left( \frac{\sin m [(x)^2 + (y)^2 + (z)^2]^\frac{1}{2}}{[(x)^2 + (y)^2 + (z)^2]^\frac{1}{2}} \cos m t' \right) \gamma^{\alpha 01}.$$  \hspace{1cm} (54)

**Remark 5** Since $\gamma^{\alpha 01} = u \gamma^{01} u^{-1}$ and $u = e^{\chi \gamma^{30}}$ we see that $F_0 \gamma^0 F_0^{-1} \in \text{sec} \bigwedge^1 T^*M \hookrightarrow \text{sec} \mathcal{C} \ell(M, g)$ and thus qualify qualifies $F_0 \gamma^0 F_0^{-1}$ as a 1-form velocity field according to Eq. (47).

Some nontrivial problems that need to be investigated are: How does the field $F_0$ behaves when it meets an obstacle, e.g., a double slit apparatus? How to describe the motion of more than one $F$ like field moving in Minkowski spacetime? We will return to this problem in another paper.

### 8 Conclusions

We proved that the relativistic Hamilton-Jacobi equation for a massive particle charged particle (moving in Minkowski spacetime) and interacting with an electromagnetic field is equivalent to a Dirac-Hestenes equation\footnote{Which is the representative of the usual Dirac equation in the Clifford bundle (a result recalled in Appendix A).} satisfied by a special class of Dirac spinor fields\footnote{These special class of spinor fields will be called classical spinor fields.} (characterized for having the Takabayashi}
angle function equal to 0 or $\pi$). Also, any Dirac-Hestenes equation satisfied by these classical spinor fields implies in a corresponding relativistic Hamilton-Jacobi equation.

After proving these results we recalled that general spinor fields which are solutions of the Dirac equation in an external potential have in general Takabayashi angle functions [1, 6] which are not constant functions). Thus, for these general spinor fields the derived generalized Hamilton-Jacobi equation (GHJE) besides having a quantum potential which must satisfy a very severe constraint (see Eq. (30)) has also a variable mass (which is a function of the Takabayashi angle function). So, the usual Hamilton-Jacobi like equations derived from Schrödinger equation used in simulations of, e.g., the double slit experiments, do not take into account that the mass of the particle which comes from the GHJE becomes a variable. This eventually must explain discrepancies found between theoretical predictions from the de Broglie and Bohm formalism and some results of experiments and inconsistencies (such as necessity of surreal trajectories) as related, by several authors (cited in the Section 1) [13]. We have also shown that de Broglie’s double solution theory can be realized at least for the case of a spinning free particle. However, contrary to de Broglie’s suggestion [7] we found that the physical field $F_0$ in Eq. (14) satisfies the massless Dirac equation instead of a nonlinear field. This finding motivates the investigation following questions:

(i) how does the field $F_0$ behave when it meets an obstacle, e.g., a double slit apparatus?

(ii) how do we describe the motion of more than one $F$-like fields moving in Minkowski spacetime?

These issues will be investigated in another paper.

The above results have been proved using the powerful Clifford and spin-Clifford bundles formalism where Dirac spinor fields are represented by an equivalence class of even sections of the Clifford bundle $\mathcal{C}(M, \eta)$ of differential forms. The Appendices present this formalism, the nomenclature and proofs of some results appearing in the main text.

Finally, while preparing this version of the paper we have been informed by Professor Basil Hiley of his papers [19, 20, 21]. In particular, the last two papers contain material related to our paper but with different and conflicting results which we intend to discuss in another publication.

A Preliminaries

Let $M$ be a four dimensional, real, connected, paracompact and non-compact manifold. We recall that a Lorentzian manifold is a pair $(M, g)$, where $g \in \sec T^2_0M$ is a Lorentzian metric of signature $(1, 3)$, i.e., $\forall x \in M, T_xM \simeq T^*_xM \simeq \mathbb{R}^{1,3}$, where $\mathbb{R}^{1,3}$ is the Minkowski vector space. We define a Lorentzian spacetime $M$ as pentuple $(M, g, D, \tau_g, \uparrow)$, where $(M, g, \tau_g, \uparrow)$ is an oriented Lorentzian

\[13\text{But on this issue see also [19].}\]
manifold (oriented by \( \tau_\mathcal{G} \)) and time oriented by \( \uparrow \), and \( \mathcal{D} \) is the Levi-Civita connection of \( \mathcal{G} \). Let \( \mathcal{U} \subseteq M \) be an open set covered by coordinates \( \{x^\mu\} \). Let \( \{e_\mu = \partial_\mu\} \) be a coordinate basis of \( T\mathcal{U} \) and \( \{\partial^\mu = dx^\mu\} \) the dual basis on \( T^*\mathcal{U} \), i.e., \( \partial^\mu(\partial_\nu) = \delta_\nu^\mu \). If \( \mathcal{G} = g_{\mu\nu} \partial^\mu \otimes \partial^\nu \) is the metric on \( T\mathcal{U} \) we denote by \( g = g^{\mu\nu} \partial_\mu \otimes \partial_\nu \) the metric of \( T^*\mathcal{U} \), such that \( g^{\mu\nu} g_{\rho\sigma} = \delta_\sigma^\nu \). We introduce also \( \{\partial^\mu\} \) and \( \{\partial_\mu\} \), respectively, as the reciprocal bases of \( \{e_\mu\} \) and \( \{\partial_\mu\} \), i.e., we have

\[
g(\partial_\mu, \partial^\nu) = \delta^\nu_\mu, \quad g(\partial^\mu, \partial_\nu) = \delta_\nu^\mu. \tag{55}\]

In what follows \( P_{\text{SO}_{1,3}}(M, \mathcal{G}) \) \((P_{\text{SO}_{1,3}}(M, \mathcal{G}))\) denotes the principal bundle of oriented Lorentz tetrads (cotetrads).

A spin structure for a general \( m \)-dimensional manifold \( M \) \((m = p + q)\) equipped with a metric field \( \mathcal{G} \) is a principal fiber bundle \( \pi : P_{\text{Spin}^e_{p,q}}(M, \mathcal{G}) \rightarrow M \), (called the Spin Frame Bundle) with a group \( \text{Spin}^e_{p,q} \) such that there exists a map

\[
\Lambda : P_{\text{Spin}^e_{p,q}}(M, \mathcal{G}) \rightarrow P_{\text{SO}}^e_{p,q}(M, \mathcal{G}), \tag{56}\]

satisfying the following conditions:

**Definition 6**

(i) \( \pi(\Lambda(p)) = \pi_s(p), \forall p \in P_{\text{Spin}^e_{p,q}}(M, \mathcal{G}), \) where \( \pi \) is the projection map of the bundle \( \pi : P_{\text{SO}}^e_{p,q}(M, \mathcal{G}) \rightarrow M \).

(ii) \( \Lambda(pu) = \Lambda(p)\text{Ad}_u, \forall p \in P_{\text{Spin}^e_{p,q}}(M, \mathcal{G}) \) and \( \text{Ad} : \text{Spin}^e_{p,q} \rightarrow \text{SO}^e_{p,q} \), \( \text{Ad}_u(a) = uau^{-1} \).

Any section of \( P_{\text{Spin}^e_{p,q}}(M, \mathcal{G}) \) is called a spin frame field (or simply a spin frame). We shall use symbol \( \Xi \in \sec P_{\text{Spin}^e_{p,q}}(M, \mathcal{G}) \) to denote a spin frame.

It can be shown that\(^{14}\)

\[
\mathcal{C}(M, \eta) = P_{\text{SO}}^e_{1,3}(M, \eta) \times_{\eta} \mathbb{R}_{1,3} = P_{\text{Spin}^e_{1,3}}(M, \eta) \times_{\text{Ad}} \mathbb{R}_{1,3}, \tag{57}\]

and since\(^{15}\) \( \wedge TM \rightarrow \mathcal{C}(M, \eta) \), sections of \( \mathcal{C}(M, \eta) \) (the Clifford fields) can be represented as a sum of non homogeneous differential forms. Notice that \( \mathbb{R}_{1,3} \) (the so-called spacetime algebra) is the Clifford algebra associated with a 4-dimensional real vector space \( (\mathbb{R}^4, \mathcal{G}) \) equipped with a metric \( \mathcal{G} \) of signature \((1,3)\). The pair \((\mathbb{R}^4, \mathcal{G})\) is denoted \( \mathbb{R}^{1,3} \) and called Minkowski vector space, which is not to be confused with Minkowski spacetime.

For any parallelizable spacetime structure (as it is the case of Minkowski spacetime used in the main text), we introduce the global tetrad basis \( e_\alpha, \alpha = 0, 1, 2, 3 \) on \( TM \) and in \( T^*M \) the cotetrad basis on \( \{\gamma^\alpha\} \), which are dual basis.

We introduce the reciprocal basis \( \{e^\alpha\} \) and \( \{\gamma_\alpha\} \) of \( \{e_\alpha\} \) and \( \{\gamma^\alpha\} \) satisfying

\[
g(e_\alpha, e^\beta) = \delta^\beta_\alpha, \quad g(\gamma^\beta, \gamma_\alpha) = \delta_\alpha^\beta. \tag{58}\]

\(^{14}\)Where \( \text{Ad} : \text{Spin}^e_{1,3} \rightarrow \text{End}(\mathbb{R}_{1,3}) \) is such that \( \text{Ad}(u) = uau^{-1} \) and \( \rho : \text{SO}^e_{1,3} \rightarrow \text{End}(\mathbb{R}_{1,3}) \) is the natural action of \( \text{SO}^e_{1,3} \) on \( \mathbb{R}_{1,3} \).

\(^{15}\)Given the objects \( A \) and \( B \), \( A \searrow B \) means as usual that \( A \) is embedded in \( B \) and moreover, \( A \subseteq B \). In particular, recall that there is a canonical vector space isomorphism between \( \wedge \mathbb{R}^{1,3} \) and \( \mathbb{R}_{1,3} \), which is written \( \wedge \mathbb{R}^{1,3} \rightarrow \mathbb{R}_{1,3} \). Details in\(^{15,24}\).
Moreover, recall that\(^{16}\)

\[
g = \eta_{\alpha \beta} \gamma^\alpha \otimes \gamma^\beta = \eta^{\alpha \beta} \gamma_\alpha \otimes \gamma_\beta, \quad g = \eta^{\alpha \beta} e_\alpha \otimes e_\beta = \eta_{\alpha \beta} e^\alpha \otimes e^\beta.
\]

(59)

In this work we have that exists a spin structure on the 4-dimensional Lorentzian manifold \((M, g)\), since \(M\) is parallelizable, i.e., \(P_{SO_{1,3}}(M, g)\) is trivial, because of the following result due to Geroch \([11,12]\):

**Theorem 7** For a 4-dimensional Lorentzian manifold \((M, g)\), a spin structure exists if and only if \(P_{SO_{1,3}}(M, g)\) is a trivial bundle \([11,12]\).

The basis \(\gamma^\alpha|_p\) of \((T_p M, g_p) \simeq \mathbb{R}^{1,3}, p \in M\), generates the algebra \(\mathcal{C}(T_p M, g) \simeq \mathbb{R}_{1,3}\). We have that \([34]\):

\[
e = \frac{1}{2}(1 + \gamma^0) \in \mathbb{R}_{1,3}
\]

is a primitive idempotent of \(\mathbb{R}_{1,3} \simeq \mathbb{H}(2)\) (the so called spacetime algebra\(^{17}\)) and

\[
f = \frac{1}{2}(1 + \gamma^0)\frac{1}{2}(1 + i\gamma^2\gamma^1) \in \mathbb{C} \otimes \mathbb{R}_{1,3}
\]

is a primitive idempotent of \(\mathbb{C} \otimes \mathbb{R}_{1,3}\). Now, let \(I = \mathbb{R}_{1,3}e\) and \(I_C = \mathbb{C} \otimes \mathbb{R}_{1,3}f\) be respectively the minimal left ideals of \(\mathbb{R}_{1,3}\) and \(\mathbb{C} \otimes \mathbb{R}_{1,3}\) generated by \(e\) and \(f\). Any \(\phi \in I\) can be written as

\[
\phi = \psi e
\]

with \(\psi \in \mathbb{R}_{1,3}^0\). Analogously, any \(\phi \in I_C\) can be written as

\[
\psi e\frac{1}{2}(1 + i\gamma^2\gamma^1)
\]

with \(\psi \in \mathbb{R}_{1,3}^0\). Recall moreover that \(\mathbb{C} \otimes \mathbb{R}_{1,3} \simeq \mathbb{R}_{4,1} \simeq \mathbb{C}(4)\). We can verify that

\[
\begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{pmatrix}
\]

is a primitive idempotent of \(\mathbb{C}(4)\) which is a matrix representation of \(f\). In that way, there is a bijection between column spinors, i.e., elements of \(\mathbb{C}^4\) and the elements of \(I_C\).

Recalling that \(\text{Spin}^e_{1,3} \hookrightarrow \mathbb{R}_{1,3}^0\), we give:

\(^{16}\)Where the matrix with entries \(\eta_{\alpha \beta}\) (or \(\eta^{\alpha \beta}\)) is the diagonal matrix \((1, -1, -1, -1)\).

\(^{17}\)We recall that \(\mathcal{C}(T^*_p M, g) \simeq \mathbb{R}_{1,3}\) the so-called spacetime algebra. Also the even subalgebra of \(\mathbb{R}_{1,3}\) denoted \(\mathbb{R}^e_{1,3}\) is isomorphic to the Pauli algebra \(\mathbb{R}_{3,0}\), i.e., \(\mathbb{R}^e_{1,3} \simeq \mathbb{R}_{3,0}\). The even subalgebra of the Pauli algebra \(\mathbb{R}^e_{3,0} := \mathbb{R}^e_{3,0} \simeq \mathbb{R}_{0,2}\) is the quaternion algebra \(\mathbb{R}_{0,2}\), i.e., \(\mathbb{R}_{0,2} \simeq \mathbb{R}^e_{3,0}\). Moreover we have the identifications: \(\text{Spin}^e_{1,3} \simeq \mathbb{S}(2, \mathbb{C}), \text{Spin}^e_{3,0} \simeq \mathbb{S}(2, \mathbb{C})\). For the Lie algebras of these groups we have \(\text{Spin}^e_{1,3} \simeq \mathfrak{sl}(2, \mathbb{C}), \mathfrak{su}(2) \simeq \mathfrak{spin}_{3,0}\). The important fact to keep in mind for the understanding of some of the identifications we done below is that \(\text{Spin}^e_{1,3}, \text{spin}^e_{1,3} \subset \mathbb{R}_{3,0} \subset \mathbb{R}_{1,3}\) and \(\text{Spin}^e_{3,0}, \text{spin}^e_{3,0} \subset \mathbb{R}_{0,2} \subset \mathbb{R}_{1,3}\).
Definition 8 The left (respectively right) real spin-Clifford bundle of the spin manifold $M$ is the vector bundle $\mathcal{C}^l_{\text{Spin}}(M, g) = P_{\text{Spin}^l_{1,3}}(M, g) \times_l \mathbb{R}_{1,3}$ (respectively $\mathcal{C}^r_{\text{Spin}}(M, g) = P_{\text{Spin}^r_{1,3}}(M, g) \times_r \mathbb{R}_{1,3}$) where $l$ is the representation of $\text{Spin}^l_{1,3}$ on $\mathbb{R}_{1,3}$ given by $l(a)x = ax$ (respectively, where $r$ is the representation of $\text{Spin}^r_{1,3}$ on $\mathbb{R}_{1,3}$ given by $r(a)x = xa^{-1}$). Sections of $\mathcal{C}^l_{\text{Spin}}(M, g)$ are called \textit{left spin-Clifford fields} (respectively right spin-Clifford fields).

Definition 9 Let $e, f \in \mathcal{C}^l_{\text{Spin}^l_{1,3}}(M, g)$ be a primitive global idempotents, respectively $e^r, f^r \in \mathcal{C}^r_{\text{Spin}^r_{1,3}}(M, g)$, and let $I(M, g)$ be the subbundle of $\mathcal{C}^l_{\text{Spin}^l_{1,3}}(M, g)$ generated by the idempotent, that is, if $\Psi$ is a section of $I(M, g) \subset \mathcal{C}^l_{\text{Spin}^l_{1,3}}(M, g)$, we have

$$\Psi e = \Psi ,$$

(60)

A section $\Psi$ of $I(M, g)$ is called a left ideal algebraic spinor field.

Definition 10 A Dirac-Hestenes spinor field (DHSF) associated with $\Psi$ is a section $\Psi$ of $\mathcal{C}^l_{\text{Spin}^l_{1,3}}(M, g) \subset \mathcal{C}^l_{\text{Spin}^l_{1,3}}(M, g)$ such that

$$\Psi = \Psi e.$$  

(61)

Definition 11 We denote the complexified left spin-Clifford bundle by

$$\mathcal{C}^l_{\text{Spin}^l_{1,3}}(M, g) = P_{\text{Spin}^l_{1,3}}(M, g) \times_l \mathbb{C} \otimes \mathbb{R}_{1,3} \equiv P_{\text{Spin}^l_{1,3}}(M, g) \times_l \mathbb{R}_{1,4}.$$  

Definition 12 An equivalent definition of a DHSF is the following. Let $\Psi \in \sec \mathcal{C}^l_{\text{Spin}^l_{1,3}}(M, g)$ such that

$$\Psi f = \Psi .$$

Then a DHSF associated with $\Psi$ is an even section $\Psi$ of $\mathcal{C}^l_{\text{Spin}^l_{1,3}}(M, g) \subset \mathcal{C}^l_{\text{Spin}^l_{1,3}}(M, g)$ such that

$$\Psi = \Psi f.$$  

(62)

The matrix representations of $\Psi$ and $\bar{\Psi}$ in $\mathbb{C}(4)$ (denoted by the same letter) in the given spin basis are

$$\Psi = \begin{pmatrix} \psi_1 & -\psi_2^* & \psi_3 & \psi_4^* \\ \psi_2 & \psi_1^* & \psi_4 & -\psi_3^* \\ \psi_3 & \psi_4^* & \psi_1 & -\psi_2^* \\ \psi_4 & -\psi_3^* & \psi_2 & \psi_1^* \end{pmatrix}, \quad \bar{\Psi} = \begin{pmatrix} \psi_1 & 0 & 0 & 0 \\ \psi_2 & 0 & 0 & 0 \\ \psi_3 & 0 & 0 & 0 \\ \psi_4 & 0 & 0 & 0 \end{pmatrix}$$  

(63)

18We know that global primitive idempotents exist because $M$ is parallelizable.

$$e = [(\Xi_0, \frac{1}{2}(1 + \gamma^0)), f = [(\Xi_0, \frac{1}{2}(1 + \gamma^0)\frac{1}{2}(1 + i\gamma^2\gamma^1))]$$

19$\mathcal{C}^l_{\text{Spin}^l_{1,3}}(M, g)$ denotes the even subbundle of $\mathcal{C}^l_{\text{Spin}^l_{1,3}}(M, g)$

20For any $\Psi$ the DHSF always exist, see [34].

21Note that in Eq. (63) the $\psi_i$ are functions from $M$ to $\mathbb{R}$. 

14
A.1 The Hidden Geometrical Meaning of Spinors

DHSFs unveil the hidden geometrical meaning of spinors (and spinor fields). Indeed, consider \( v \in \mathbb{R}_{1,3} \rightarrow \mathbb{R}_{1,3} \) a timelike covector such that \( v^2 = 1 \). The linear mapping, belonging to \( \text{SO}_{1,3}^c \)

\[
v \mapsto R v R^{-1} = R v = w, \quad R \in \text{Spin}_{1,3},
\]

(64)

define a new covector \( w \) such that \( w^2 = 1 \). We can therefore fix a covector \( v \) and obtain all other unit timelike covectors by applying this mapping. This same procedure can be generalized to obtain any type of timelike covector starting from a fixed unit covector \( v \). We define the linear mapping

\[
v \mapsto \psi v \bar{\psi} = z
\]

(65)

to obtain \( z^2 = \rho^2 > 0 \). Since \( z \) can be written as \( z = \rho R v \bar{R} \), we need

\[
\psi \bar{\psi} = \rho R v \bar{R}.
\]

(66)

If we write \( \psi = \rho^2 M R \) we need that \( M v \bar{M} = v \) and the most general solution is \( M = e^{-2 g} \), where \( \tau_\eta = \gamma^0 \gamma^1 \gamma^2 \gamma^3 \in \wedge^4 \mathbb{R}_{1,3} \rightarrow \mathbb{R}_{1,3} \) and \( \beta \in \mathbb{R} \) is called the Takabayasi angle \([34, 37]\). Then it follows that \( \psi \) is of the form

\[
\psi = \rho^2 e^{2 \tau_\eta} R.
\]

(67)

Now, Eq. (67) shows that \( \psi \in \mathbb{R}_{1,3}^0 \simeq \mathbb{R}_{3,0} \). Moreover, we have that \( \psi \bar{\psi} \neq 0 \) since

\[
\psi \bar{\psi} = \rho e^{\tau_\eta} = (\rho \cos \beta) + \tau_\eta (\rho \sin \beta).
\]

(68)

A representative of a DHSF \( \Psi \) in the Clifford bundle \( \mathcal{C}(M, g) \) relative to a spin frame \( \Xi_u \) is a section \( \psi_{\Xi_u} = (\Xi_u, \psi_{\Xi_u}) \) of \( \mathcal{C}^0(M, g) \) where \( \psi_{\Xi_u} \in \mathbb{R}_{1,3}^0 \simeq \mathbb{R}_{3,0} \). So a DHSF such \( \psi_{\Xi_u} \psi_{\Xi_u} \neq 0 \) induces a linear mapping induced by Eq. (65), which rotates a covector field and dilate it.

B Description of the Dirac Equation in the Clifford Bundle

In the main text we utilized as arena for the motion of particles (and fields) the Minkowski spacetime structure \((M \simeq \mathbb{R}^4, \eta, D, \tau_\eta)\). Object \( \eta \in \text{sec} T^2_\eta M \) is the Minkowski metric field and \( D \) is the Levi-Civita connection of \( \eta \). Also, \( \tau_\eta \in \text{sec} \wedge^4 T^* M \) defines an orientation. We denote by \( \eta \in \text{sec} T^2 \eta M \) the metric of the cotangent bundle. It is defined as follows. Let \( \{x^\mu\} \) be coordinates for \( M \) in the Einstein-Lorentz-Poincaré gauge \([34]\). Let \( \{e_\mu = \partial / \partial x^\mu \} \) a basis for \( TM \) and \( \{\gamma^\mu = dx^\mu\} \) the corresponding dual basis for \( T^* M \), i.e., \( \gamma^\mu(e_\alpha) = \delta^\mu_\alpha \). Then, if \( \eta = \eta_{\mu\nu} \gamma^\mu \otimes \gamma^\nu \) then \( \eta = \eta_{\mu\nu} e_\mu \otimes e_\nu \), where the matrix with entries \( \eta_{\mu\nu} \) and the one with entries \( \eta^\mu_\nu \) are the equal to the diagonal matrix \( \text{diag}(1, -1, -1, -1) \). If
a, b ∈ sec^1 T^* M we write a · b = η(a, b). We also denote by \(\{\gamma_\mu = dx^\mu\}\) the reciprocal basis of \(\{\gamma_\mu = dx^\mu\}\), which satisfies \(\gamma^\mu \cdot \gamma_\mu = \delta^\mu_\nu\).

We denote the Clifford bundle of differential forms in Minkowski spacetime by \(\mathcal{C}(M, \eta)\) and use notations and conventions in what follows as in [34] and recall the fundamental relation

\[
\gamma^\mu \gamma^\nu + \gamma^\nu \gamma^\mu = 2\eta^{\mu \nu}.
\]

If \(\gamma_\mu, \mu = 0, 1, 2, 3\) are the Dirac gamma matrices in the standard representation and \(\gamma_\mu, \mu = 0, 1, 2, 3\) are as introduced above, we define

\[
\sigma_k := \gamma_k \gamma_0 \in \sec^2 T^* M \hookrightarrow \sec \mathcal{C}(M, \eta), \quad k = 1, 2, 3,
\]

\[
i = \gamma_5 := \gamma_0 \gamma_1 \gamma_2 \gamma_3 \in \sec^4 T^* M \hookrightarrow \sec \mathcal{C}(M, \eta),
\]

\[
\gamma_5 := \gamma_0 \gamma_1 \gamma_2 \gamma_3 \in \mathbb{C}(4)
\]

Noting that \(M\) is parallelizable, given a global spin frame a covariant spinor field can be taken as a mapping \(\Psi : M \rightarrow \mathbb{C}^4\) in standard representation of the gamma matrices where \((i = \sqrt{-1}, \phi, \varsigma : M \rightarrow \mathbb{R}^2)\) \(\psi\) is given by

\[
\Psi = \begin{pmatrix} \phi \\ \varsigma \end{pmatrix} = \begin{pmatrix} m^0 + i m^3 \\ -m^2 + i m^1 \\ n^0 + i n^3 \\ -n^2 + i n^1 \end{pmatrix},
\]

and to \(\Psi\) there corresponds the DHSF \(\psi \in \sec \mathcal{C}(M, \eta)\) given by

\[
\psi = \phi + \varsigma \sigma_3 = (m^0 + m^k i \sigma_k) + (n^0 + n^k i \sigma_k) \sigma_3.
\]

We then have the useful formulas in Eq. (75) below that one can use to immediately translate results of the standard matrix formalism in the language of the Clifford bundle formalism and vice-versa:

\[
\gamma_\mu \Psi \leftrightarrow \gamma_\mu \psi \gamma_0,
\]

\[
i \Psi \leftrightarrow \psi \gamma_{21} = \psi i \sigma_3,
\]

\[
i \gamma_5 \Psi \leftrightarrow \psi \sigma_3 = \psi \gamma_3 \gamma_0,
\]

\[
\tilde{\Psi} = \Psi^\dagger \gamma^0 \leftrightarrow \tilde{\psi},
\]

\[
\Psi^\dagger \leftrightarrow \gamma_0 \tilde{\psi} \gamma_0,
\]

\[
\Psi^* \leftrightarrow -\gamma_2 \tilde{\psi} \gamma_2.
\]

Using the above dictionary the standard (free) Dirac equation for a Dirac spinor field \(\psi : M \rightarrow \mathbb{C}^4\)

\[
i \gamma^\mu \partial_\mu \Psi - m \Psi = 0
\]

\[22\]Remember the identification: \(\mathbb{C}(4) \simeq \mathbb{R}_{4,1} \supseteq \mathbb{R}_{4,1}^0 \simeq \mathbb{R}_{1,3}^0\).

\[23\]\(\tilde{\psi}\) is the reverse of \(\psi\). If \(A_r \in \sec \bigwedge^r T^* M \hookrightarrow \sec \mathcal{C}(M, \eta)\) then \(\tilde{A}_r = (-1)^{r(r-1)} A_r\).

\[24\]\(\partial_\mu := \frac{\partial}{\partial x^\mu}\).
translates immediately in the so-called Dirac-Hestenes equation, i.e.,
\[ \partial \psi \gamma_{21} - m \psi \gamma_0 = 0. \quad (77) \]

**C Proof of Eq. (20)**

From Eqs. (15), (16) and (17) we have that
\[ \Pi + eA = mV = mR \gamma^0 R^{-1} = L \gamma^0 L^{-1} \quad (78) \]

This means that the rotor \( R : M \ni x \mapsto R(x) \in \text{Spin}_{1,3}^0 \) must be a boost. We also know that every boost must be the exponential of a biform \[38, 26\].

Now, we observe that for any \( x \in M \) if \( X(x) \) is such that
\[ X(x) \gamma((\Pi + eA) \wedge \gamma^0) = 0 \quad (79) \]
we will have
\[ RXR^{-1} = X \quad (80) \]
and thus we conclude that \( R \) must be a biform proportional to \( C = \gamma^0 \wedge (\Pi + eA) \).

Indeed, since \( (\Pi + eA) \wedge \gamma^0 \) anticommutes with \( (\Pi + eA) \) and \( \gamma^0 \) we have that
\[ \frac{1}{m} \Pi + eA = R \gamma^0 R^{-1} = R^2 \gamma^0 = V \quad (81) \]

As we can verify by direct computation the have
\[ R(V) = \frac{1 + V \gamma^0}{1 [2 (1 + V \gamma^0)]^{1/2}} \quad (82) \]
and thus we can write
\[ R(\Pi) = \frac{m + (\Pi + eA) \gamma^0}{[2 (m + \Pi_0 + A_0)]^{1/2}} \quad (83) \]
with
\[ \cosh \chi = \frac{1}{m} (\Pi_0 + A_0) \quad (84) \]

Now, without any difficulty we can show that
\[ R(\Pi) = e^{\frac{\chi}{2} \frac{(\Pi + eA) \wedge \gamma^0}{[(\Pi + eA) \wedge \gamma^0]}} \quad (85) \]

For the case where \( A = 0 \) the canonical momentum is \( P \), with \( P^2 = m^2 \). In this case \[9\] Eq. \[83\] is
\[ R(P) = \frac{m + V \gamma^0}{[2m (m + P^0)]^{1/2}}. \quad (86) \]
D Rotation and Fermi Transport in the Clifford Bundle Formalism

Let $\sigma : \mathbb{R} \ni t \mapsto M, \tau \mapsto \sigma(\tau)$ be a timelike curve on Minkowski spacetime. Let $Y$ be a vector field over $\sigma$. As well known \cite{33}, in order for an observer (following the curve $\sigma$) to decide when a unitary vector $Y \in (\sigma_{\tau'})^\perp$ has the same spatial direction of the unitary vector $Y' \in (\sigma_{\tau'})^\perp (\tau' \neq \tau)$, he has to introduce the concept of the Fermi-Walker connection. We have the

**Proposition 13** There exists one and only one connection $\mathcal{F}$ over $\sigma$, such that

$$\mathcal{F}_X Y = [p(\sigma^* D)_X p + q(\sigma^* D)_X q] Y$$

for all vector fields $X$ on $I$ and for all vector fields $Y$ over $\sigma$.

In Eq. (87) $\sigma^* D$ is the induced connection over $\sigma$ of the Levi-Civita connection $D$ and $\mathcal{F}$ is called the Fermi-Walker connection over $\sigma$, and we shall use the notations $\mathcal{F}_\sigma, \mathcal{F}/d\tau$ or $\mathcal{F}_\mathcal{E}_0$ (see below) when convenient. We also will write (by abuse of language) only $D$, as usual, for $\sigma^* D$ in what follows. A proof of the theorem can be found, e.g., in \cite{34}.

We recall that a moving (orthonormal) frame $\{\epsilon_a\}$ over $\sigma$ is an orthonormal basis for $T_{\sigma(t)} M$ with $\epsilon_0 = \sigma_*$. The set $\{\epsilon^a\}$, $\epsilon^a \in \sec T^*_{\sigma(t)} M \hookrightarrow \sec \mathcal{C}(M, \eta)$ is the dual comoving frame on $\sigma$, i.e., $\epsilon^a(\epsilon_b) = \delta^a_b$. The set $\{\epsilon_a\}, \epsilon_a \in \sec T^*_{\sigma(t)} M \hookrightarrow \sec \mathcal{C}(M, \eta)$, with $\epsilon^a \cdot \epsilon_b = \delta^a_b$ is the reciprocal frame of $\{\epsilon^a\}$.

Let $X$ and $Y$ be vector fields over $\sigma$ and $Y = \eta(X, \cdot), Y = \eta(Y, \cdot) \in \sec T^*_{\sigma(t)} M \hookrightarrow \mathcal{C}(M, \eta)$ the physically equivalent 1-form fields. We have the

**Proposition 14** Let be $X, Y$ be form fields over $\sigma$, as defined above. The Fermi-Walker connection $\mathcal{F}$ satisfies the properties

(a) $\mathcal{F}_\sigma Y = D_{\epsilon_0} Y - (\epsilon_0 \cdot Y) a + (a \cdot Y) \epsilon_0$, where $a = D_{\epsilon_0} \epsilon_0$, is the (1-form) acceleration.

(b) $\frac{d}{dt}(X \cdot Y) = \mathcal{F}_{\epsilon_0} X \cdot Y + X \cdot \mathcal{F}_{\epsilon_0} Y$.

(c) $\mathcal{F}_{\epsilon_0} \epsilon_0 = 0$.

(d) If $X, Y$ are vector fields on $\sigma$ such that $X_u, Y_u \in H_u \forall u \in I$ then $\eta(\mathcal{F}_{\epsilon_0} X, \cdot)_{\mid_u}$ and $\eta(\mathcal{F}_{\epsilon_0} Y, \cdot)_{\mid_u}$ in $H_u, \forall u$ and

$$\mathcal{F}_{\epsilon_0} X \cdot Y = D_{\epsilon_0} X \cdot Y.$$  

For a proof, see, e.g., \cite{34}.

Now, let $Y_0 \in \sec T^*_{\sigma_{\tau_0}} M$. Then, by a well known property of connections there exists one and only one 1-form field $Y$ over $\sigma$ such that $\mathcal{F}_{\epsilon_0} Y = 0$ and $Y(\tau_0) = Y_0$. So, if $\{\epsilon_a\}_{\mid_{\tau_0}}$ is an orthonormal basis for $T^*_{\sigma_{\tau_0}} M (\epsilon_a|_{\tau_0} \in T^*_{\sigma_{\tau_0}} M, a = 0, 1, 2, 3)$ we have that the $\epsilon_a$’s such that $\mathcal{F}_{\epsilon_0} \epsilon_a = 0$ are orthonormal for any $\tau$, as follows from (b) in proposition 14.

---

25 Recall the notations introduced in Chapter 4, where $g$ denote the metric in the cotangent bundle.
We then agree to say that $Y_1 \in H_{\tau_1}^∗$ and $Y_2 \in H_{\tau_2}^∗$ have the same spatial direction if and only if $Y_1 = a^i \varepsilon_i|_{\tau_1}$, $Y_2 = a^i \varepsilon_i|_{\tau_2}$. This suggests the following

**Definition 15** We say that $Y \in \sec T^*_\sigma M$ is transported without rotation (Fermi transported) if and only if $\mathcal{F}_\alpha Y = 0$.

In that case we have

$$D_{\varepsilon_0} Y = \varepsilon_0 \cdot \partial Y \equiv \frac{D}{dt} Y = (Y \cdot \varepsilon_0) a - (a \cdot Y) \varepsilon_0 = Y \omega(\varepsilon_0 \wedge a) = (a \wedge \varepsilon_0) \wedge Y.$$  \hfill (89)

**D.1 Frenet Frames over $\sigma$ and the Darboux Biform**

**Proposition 16** If $\{\varepsilon_a\}$ is a comoving coframe over $\sigma$, then there exists a unique biform field $\Omega_D$ over $\sigma$, called the angular velocity (Darboux biform) such that the $\varepsilon_a$ satisfy the following system of differential equations

$$D_{\varepsilon_0} \varepsilon_a = \Omega_D \cdot \varepsilon_a,$$

$$\Omega_D = \frac{1}{2} \omega_{ab} \varepsilon^a \wedge \varepsilon^b = -\frac{1}{2} (D_{\varepsilon_0} \varepsilon_b) \wedge \varepsilon^b.$$  \hfill (90)

**Proof.** The proof is trivial and we also have the following □

**Corollary 17** If the comoving coframe $\{\varepsilon_a\}$ is Fermi transported then the angular velocity is $\Omega_F$,

$$\Omega_F = a \wedge \varepsilon_0.$$  \hfill (91)

**D.2 Physical Meaning of Fermi Transport**

Suppose that a comoving coframe $\{\varepsilon_a\}$ is Fermi transported along a timelike curve $\sigma$, ‘materialized’ by some particle. The physical meaning associated to Fermi transport is that the spatial axis of the tetrad $\eta(\varepsilon_i, \varepsilon_0) = \varepsilon_i, i = 1, 2, 3$ are to be associated with the orthogonal spatial directions of three small gyroscopes carried along $\sigma$.

**Definition 18** A Frenet coframe $\{f_a\}$ over $\sigma$ is a moving coframe over $\sigma$ such that $f_0 = g(\sigma, \cdot) = g(\varepsilon_0, \cdot) = \varepsilon_0$ and

$$D_{\varepsilon_0} f_a = \Omega_D \cdot f_a,$$

$$\Omega_D = \kappa_0 f^1 \wedge f^0 + \kappa_1 f^2 \wedge f^1 + \kappa_2 f^3 \wedge f^2,$$  \hfill (92)

where $\kappa_i, i = 0, 1, 2$ is the i-curvature, which is the projection of $\Omega_D$ in the $f^{i+1} \wedge f^i$ plane.

**Definition 19** We say that a 1-form field $Y$ over $\sigma$ is rotating if and only if it is rotating in relation to gyroscopes axis, i.e., if $\mathcal{F}_\alpha Y \neq 0$. 

19
D.3 Rotation 2-form, the Pauli-Lubanski Spin 1-Form and Classical Spinning Particles

From Eq. 92 taking into account that \( \alpha = D_\alpha f_0 = \kappa_0 f^1 \) and Eq. 91 we can write

\[
\Omega_D = a \land f_0 + \Omega_s. \tag{93}
\]

We now show that the 2-form \( \Omega_s \) over \( \sigma \) is directly related (a dimensional factor apart) with the spin 2-form of a classical spinning particle. More, we show now that the Hodge dual of \( \Omega_s \) is associated with the Pauli-Lubanski 1-form. To have a notation as closely as possible the usual ones of physical textbooks, let us put \( f_0 = v \).

Call \( *\Omega_s \) the Hodge dual of \( \Omega_s \). It is the 2-form over \( \sigma \) given by

\[
*\Omega_s = -\Omega_s f^5, \quad f^5 = f^0 f^1 f^2 f^3. \tag{94}
\]

Define the rotation 1-form \( S \) over \( \sigma \) by

\[
S = -*\Omega_s v. \tag{95}
\]

Since \( *\Omega_s v = 0 \), we have immediately that

\[
S \cdot v = -*\Omega_s (v \land v) = 0. \tag{96}
\]

Now, since \( D_\alpha (S \cdot v) = 0 \) we have that \( (D_\alpha S) \cdot a = -S \cdot a \) and then

\[
D_\alpha S = -S \perp (a \land v), \tag{97}
\]

and it follows that

\[
F_\alpha S = 0. \tag{98}
\]

It is intuitively clear that we must associate \( S \) with the spin of a classical spinning particle which follows the worldline \( \sigma \). And, indeed, we define the Pauli-Lubanski spin 1-form by

\[
W = k\hbar S, \quad \hbar = 1, \tag{99}
\]

where \( k > 0 \) is a real constant and \( \hbar \) is Planck constant, which is equal to 1 in the natural system of units used in this paper. We recall that as it is well-known \( D_\alpha W = -W \perp (a \land v) \) is the equation of motion of the intrinsic spin of a classical spinning particle which is being accelerated by a force producing no torque.
