Abstract

We study some aspects of low-energy effective actions in 4-d superconformal
gauge theories on the Coulomb branch. We describe superconformal invariants
constructed in terms of the $\mathcal{N} = 2$ abelian vector multiplet which play the role of
building blocks for the $\mathcal{N} = 2, 4$ low-energy effective actions. We compute the
one-loop effective actions in constant $\mathcal{N} = 2$ field strength background in $\mathcal{N} = 4$
SYM theory and in $\mathcal{N} = 2$ SU(2) SYM theory with four hypermultiplets in the
fundamental representation. Using a classification of superconformal invariants, we
then find the manifestly $\mathcal{N} = 2$ superconformal form of these effective actions. While
our explicit computations are done in the one-loop approximation, our conclusions
about the structure of the effective actions in $\mathcal{N} = 2$ superconformal theories are
general. We comment on some relations to supergravity–gauge theory duality in
the description of D-brane interactions.

1 Introduction

The study of the structure of low-energy effective actions in $d = 4$ superconformal theories is an important subject from several point of view, in particular, in connection with interactions of D-branes in string theory. Systems of D3-branes have complementary descriptions in terms of gauge theory and supergravity. As one of the consequences, the leading-order interaction potential between separated branes admits two equivalent representations: as a classical supergravity potential between a probe and a source, and as a leading term in the quantum gauge theory effective action. The agreement between the supergravity and the gauge theory expressions for the potential is possible because of the existence of certain non-renormalization theorems on the gauge theory side (see [1, 2] and references there).

One may conjecture that not only the $F^4/X^4$ term but all higher terms

$$
\sum_{n=1}^{\infty} c_n (g^2 N)^{n-1} \frac{F^{2n+2}}{X^{4n}}
$$

in the Born-Infeld action for a D3-brane probe moving near the core of a multiple D3-brane source (or in $AdS_5 \times S^5$ space) may be reproduced by the leading low-energy, large $N$, part of the quantum $\mathcal{N} = 4 \ SU(N)$ SYM effective action. The latter is obtained by keeping the $U(1) \ N = 4$ vector multiplet as an external background and integrating out massive SYM fields (see, e.g., [3, 4, 5, 6] and refs. there). This conjecture seems likely to be true at the first subleading order, i.e. for the $F^6/X^8$ term. Indeed, it is easy to show that this term is not present in the $\mathcal{N} = 4$ SYM analog [8] of the 1-loop Schwinger effective action, and the result of [7] for the dimensionally reduced 0+1 gauge theory suggests that this $F^6$ term should appear in the 2 loop effective action with precisely the right coefficient to match the supergravity expression.

This conjecture seems, however, to run into a problem at the next order of the $F^8/X^{12}$ term. According to the supergravity expression (1.1), it should appear in the SYM action only at the 3-loop order, but the 1-loop SYM effective action already contains $O(F^8)$ term. One may hope that the $F^8$ term does not receive corrections beyond the 3-loop order, so that the 3-loop correction dominates over the 1-loop and 2-loop terms in the supergravity limit ($g^2 N \gg 1$). Still, this may not be enough for the agreement since the $F^8$ invariants in the 1-loop SYM effective action and in the Born-Infeld D3-brane action happen to have different Lorentz index structure.

In order to shed more light on this problem of the supergravity–SYM correspondence one may study the constraints imposed by the superconformal invariance (which is a
natural symmetry of the supergravity “D3-brane in $AdS_5 \times S^5$” action \[9, 10, 11\]) on the structure of the SYM effective action.\(^1\) A possible strategy is to start with the 1-loop expression for the low-energy effective action on the Coulomb branch written in the manifestly superconformally invariant form and try to draw some general lessons about the form of the effective action which may go beyond the 1-loop order.

In this paper we shall consider two superconformal theories in four dimensions – the $\mathcal{N} = 4$ $SU(2)$ SYM and the $\mathcal{N} = 2$ $SU(2)$ SYM with four hypermultiplets in the fundamental representation of $SU(2)$, with the gauge group spontaneously broken to its $U(1)$ subgroup. We will be mainly interested in the part of their low-energy effective actions of $\mathcal{N} = 2$, 4 superconformal theories which involves the physical bosonic fields of $\mathcal{N} = 2$ vector multiplet (vector field strength and scalars). We will compute the one-loop effective actions in the constant field background

$$\mathcal{W}|_{\theta = 0} = X = \text{const} , \quad D_\alpha^i \mathcal{W}|_{\theta = 0} = \psi^i_\alpha = \text{const} ,$$
$$D_{(\alpha} D_{\beta)}^i \mathcal{W}|_{\theta = 0} = 8 F_{\alpha \beta} = \text{const} , \quad D^{\alpha(i} D^{j)}_\alpha \mathcal{W}|_{\theta = 0} = 0 , \quad (1.2)$$

which is a special supersymmetric solution of the equations of motion of the abelian $\mathcal{N} = 2$ vector multiplet ($\mathcal{W}$ is the $\mathcal{N} = 2$ gauge superfield strength). The fact that the theories under consideration are superconformal will allow us to use the classification of superconformal invariants constructed in terms of the abelian $\mathcal{N} = 2$ vector multiplet (section 2). As a result, we will be able to restore not only the known $F^4$–type quantum corrections

$$\int \! d^{12}z \, \mathcal{H}(\mathcal{W}, \bar{\mathcal{W}}) , \quad \mathcal{H}(\mathcal{W}, \bar{\mathcal{W}}) \propto \ln \mathcal{W} \ln \bar{\mathcal{W}} \quad (1.3)$$

computed previously (for $\mathcal{N} = 4$ SYM) using supergraph techniques \[22, 25\] (see also \[15, 16, 17\]), but also all terms in the effective action

$$\Gamma = c \int \! d^{12}z \, \ln \mathcal{W} \ln \bar{\mathcal{W}} + \int \! d^{12}z \, \ln \mathcal{W} \, \Lambda \left( \bar{\mathcal{W}}^{-2} D^4 \ln \mathcal{W} \right) + \text{c.c.}$$
$$+ \int \! d^{12}z \, \Upsilon \left( \bar{\mathcal{W}}^{-2} D^4 \ln \mathcal{W} , \, \mathcal{W}^{-2} \bar{D}^4 \ln \bar{\mathcal{W}} \right) , \quad (1.4)$$

which generate the quantum corrections of the form (1.1) in components ($\Lambda$ and $\Upsilon$ are specific functions of their arguments). While our explicit computations will be done in the one-loop approximation, our conclusions about the general structure of the effective action in superconformal theories have a universal, loop-independent, character.

\(^1\)Some implications of special conformal transformations in $\mathcal{N} = 4$ SYM theory in the context of AdS/CFT correspondence were considered in \[21\].
The paper is organized as follows. In section 2 we describe superconformal invariants of the $\mathcal{N} = 2$ abelian vector multiplet, which appear as building blocks for the effective actions of $\mathcal{N} = 2, 4$ superconformal theories.

In section 3 we start with the one-loop effective action of $\mathcal{N} = 4$ SYM computed for the constant field background (1.2), and then restore its general $\mathcal{N} = 2$ superfield form using superconformal invariance considerations.

In section 4 the analysis of section 3 is extended to the case of $\mathcal{N} = 2$ SU(2) SYM with four fundamental hypermultiplets. We find that a specific feature of the $\mathcal{N} = 4$ super Yang-Mills theory that there are no $\Lambda$–type quantum corrections (second term in (1.4)) in the 1-loop effective action (in particular, the absence of the induced $F^6$ term) is not shared by generic $\mathcal{N} = 2$ superconformal theories. This unique property of the $\mathcal{N} = 4$ theory should be a consequence of a hidden $\mathcal{N} = 4$ superconformal symmetry.

Section 5 contains concluding remarks. Some useful facts about $\mathcal{N} = 1, 2$ superconformal transformations are collected in Appendix.

## 2 Superconformal invariants of $\mathcal{N} = 2$ vector multiplet

In this section we present superconformal invariants of an abelian $\mathcal{N} = 2$ vector multiplet described by a chiral superfield $\mathcal{W}(z)$ and its conjugate $\bar{\mathcal{W}}(z)$ which are subject to the standard off-shell constraints [12]

$$
\bar{D}_a \mathcal{W} = D^i_{\dot{a}} \bar{\mathcal{W}} = 0, \quad i = 1, 2
$$

$$
D^{ij} \mathcal{W} = \bar{D}^{ij} \bar{\mathcal{W}} , \quad D^{ij} \equiv D^{a(i} D^{j)}_{\dot{a}} , \quad \bar{D}^{ij} \equiv \bar{D}^{\dot{a}(i} D^{j)\dot{a}} .
$$

The $\mathcal{N} = 2$ superconformal transformation law of $\mathcal{W}$ reads

$$
\delta \mathcal{W} = -\xi \mathcal{W} - 2\sigma \mathcal{W} .
$$

Here $\xi = \xi^A D_A$ is a superconformal Killing vector, the chiral scalar $\sigma$ is defined by eq. (A.8), see Appendix for more details. It follows then that the classical vector multiplet action

$$
S_{\text{vm}} = \frac{1}{4} \int d^4x \, d^4\theta \, \mathcal{W}^2
$$

is, of course, superconformal invariant.
Let us assume that $\cal W$ possesses a non-vanishing expectation value, as is the case in $\cal N = 2, 4$ superconformal models with the gauge group spontaneously broken to its maximal compact subgroup. Then, using the results of Appendix, one check that the following (anti) chiral combinations
\begin{align}
\Psi^2 &= \frac{1}{16W^2} D^4 \ln \frac{\cal W}{\mu} , \quad D^4 = (D_1)^2 (D_2)^2 \\
\bar{\Psi}^2 &= \frac{1}{16\bar{\cal W}^2} D^4 \ln \frac{\bar{\cal W}}{\mu} , \quad D^4 = (\bar{D}_1)^2 (\bar{D}_2)^2
\end{align}
transform as scalars with respect to the $\cal N = 2$ superconformal group,
\begin{equation}
\delta \Psi^2 = -\xi \Psi^2 , \quad \delta \bar{\Psi}^2 = -\xi \bar{\Psi}^2.
\end{equation}
Using the fact that $\cal N = 2$ superconformal transformations preserve the $\cal N = 2$ superspace measure $d^{12}z = d^4x d^4\theta d^4\bar{\theta}$,
\begin{equation}
(-1)^A D_A \xi^A = 0 ,
\end{equation}
one can construct three types of $\cal N = 2$ superconformal invariants
\begin{align}
S_1 &= \int d^{12}z \ln \frac{\cal W}{\mu} \ln \frac{\bar{\cal W}}{\mu} , \\
S_2 &= \int d^{12}z \Lambda (\bar{\Psi}^2) \ln \frac{\cal W}{\mu} + \text{c.c.} , \\
S_3 &= \int d^{12}z \Upsilon (\Psi^2, \bar{\Psi}^2) ,
\end{align}
where $\Lambda$ and $\Upsilon$ are arbitrary holomorphic and real analytic functions, respectively. These functionals are the main data describing quantum corrections of the form (1.1) (along with special contributions with derivatives of the fields required by supersymmetry) which appear in the low-energy effective actions of $\cal N = 2, 4$ superconformal theories.

There exist additional superconformal invariants constructed in terms of
\begin{equation}
\Sigma^{ij} = \frac{1}{\cal W \bar{\cal W}} D^{ij} \cal W = \frac{1}{\cal W \bar{\cal W}} D^{ij} \bar{\cal W} ,
\end{equation}
where the primary field $D^{ij} \cal W$ transforms as follows
\begin{equation}
\delta D^{ij} \cal W = -\xi D^{ij} \cal W - 2i \hat{\Lambda}_k^{(i} D^{j)k} \cal W - 2(\sigma + \bar{\sigma}) D^{ij} \cal W.
\end{equation}

\footnote{Here $\mu$ is a formal scale which is introduced to make the argument of the logarithm dimensionless. It drops out from all superconformal structures listed below.}
\footnote{Chiral-like superconformal invariants, $\int d^4x d^4\theta \cal W^2 H (\Psi^2) + \text{c.c.}$, are equivalent to $S_2$.}
\footnote{$\Upsilon (\Psi^2, \bar{\Psi}^2)$ is defined modulo Kähler–like shifts $\Upsilon (\Psi^2, \bar{\Psi}^2) \to \Upsilon (\Psi^2, \bar{\Psi}^2) + \Xi (\Psi^2) + \bar{\Xi} (\bar{\Psi}^2)$.}
However, $\Sigma^{ij}$ involves the free equation of motion of the $\mathcal{N} = 2$ vector multiplet. As is well-known, contributions to effective action, which contain the classical equations of motion factor, are ambiguous (in particular, gauge dependent). For that reason we will ignore $\Sigma$-dependent quantum corrections in what follows.

A large number of nontrivial superconformal invariants can be obtained by noting that for a primary superfield $\Gamma_{ij} = \Gamma_{ji}$ with the transformation law

$$\delta \Gamma_{ij} = -\xi \Gamma_{ij} + 2\sigma \Gamma_{ij} + 2i \hat{\Lambda}_{(i} k \Gamma_{j)k} ,$$

its descendant $D^{ij} \Gamma_{ij}$ is also primary,

$$\delta D^{ij} \Gamma_{ij} = -\xi D^{ij} \Gamma_{ij} + 2 (\sigma - \bar{\sigma}) D^{ij} \Gamma_{ij} .$$

(2.12)

Given an arbitrary function $f(\Psi^2, \bar{\Psi}^2)$, the superfield $\mathcal{W} f(\Psi^2, \bar{\Psi}^2)$ transforms like $\mathcal{W}$, and therefore $\Gamma_{ij} \equiv (\mathcal{W}^2 \bar{\mathcal{W}})^{-1} D^{ij} \left( \mathcal{W} f(\Psi^2, \bar{\Psi}^2) \right)$ has the superconformal transformation law (2.12). As a consequence, the following combinations

$$\mathcal{W} D^{ij} \left\{ \frac{1}{\mathcal{W}^2 \bar{\mathcal{W}}^2} D_{ij} \left( \mathcal{W} f(\Psi^2, \bar{\Psi}^2) \right) \right\} ,$$

$$\bar{\mathcal{W}} \bar{D}^{ij} \left\{ \frac{1}{\mathcal{W}^2 \bar{\mathcal{W}}^2} D_{ij} \left( \mathcal{W} f(\Psi^2, \bar{\Psi}^2) \right) \right\}$$

(2.14)

are superconformal scalars. One more possibility to generate superconformal scalars is to take $SU(2)$ invariant products of several superfields of the form

$$\frac{1}{\mathcal{W} \bar{\mathcal{W}}} D^{ij} \left( \mathcal{W} f(\Psi^2, \bar{\Psi}^2) \right)$$

(2.15)

and their conjugates which transform similar to $\Sigma^{ij}$. Then one can repeat the construction of superconformal invariants discussed above by replacing the arguments of $f(\Psi^2, \bar{\Psi}^2)$ by other superconformal scalars, etc.

In this paper, we are mainly interested in the part of the low-energy effective action of $\mathcal{N} = 2, 4$ superconformal theories, which involves the physical bosonic fields of $\mathcal{N} = 2$ vector multiplet, i.e. the $U(1)$ field strength and its scalar superpartners, without higher derivatives. The crucial point is that all relevant component structures are then generated by the superconformal invariants of the three types given in (2.7), (2.8), (2.9). It should be noted that while many component structures of interest can be also obtained from the superconformal invariants generated by (2.14), (2.15) and their descendants, the difference between the two descriptions is only in terms which involve higher derivatives of the fields.
Let us represent $W$ in terms of its $\mathcal{N} = 1$ superfield parts\(^5\)

$$W = \Phi, \quad D_\alpha^2 W = 2i W_\alpha,$$  
(2.16)

where we used the notation $U = U(z)|_{\theta_2 = \bar{\theta}_2 = 0}$, for any $\mathcal{N} = 2$ superfield $U$. Then

$$\bar{\Psi}^2 = \frac{1}{4\Phi^2} D^2 \left( \frac{W^2}{\Phi^2} + \frac{1}{4\Phi} \bar{D}^2 \Phi \right) \equiv \bar{\Psi}^2 + \frac{1}{16\Phi^2} D^2 \bar{D}^2 \frac{\Phi}{\Phi}.$$  
(2.17)

From the $\mathcal{N} = 1$ superconformal transformations

$$\delta \Phi = -\xi \Phi - 2\sigma \Phi, \quad \delta W_\alpha = -\xi W_\alpha + \hat{\omega}_\alpha^\beta W_\beta - 3\sigma W_\alpha,$$  
(2.18)

it follows that the (anti) chiral combinations

$$\bar{\Psi}^2 = \frac{1}{4\Phi^2} D^2 \left( \frac{W^2}{\Phi^2} \right), \quad \Psi^2 = \frac{1}{4\Phi^2} \bar{D}^2 \left( \frac{\bar{W}^2}{\Phi^2} \right)$$  
(2.19)

transform as *scalars* with respect to the $\mathcal{N} = 1$ superconformal group.

### 3 $\mathcal{N} = 4$ super Yang-Mills theory

In this section we analyze the low-energy effective action of the $\mathcal{N} = 4$ $SU(2)$ super Yang-Mills theory with the gauge group broken to $U(1)$. A generalization to the case of an arbitrary semi-simple gauge group spontaneously broken to its maximal abelian subgroup is straightforward and can be done as in refs. [15, 16, 17] where the leading superfield correction to the low-energy action was computed.

Our aim will be to find the manifestly superconformal invariant generalization of the well-known Schwinger-type expression for the bosonic part of the 1-loop effective action of $\mathcal{N} = 4$ SYM theory in the purely bosonic $F_{mn} = \text{const}$ background. The use of the superconformal invariance requirement may allow, in principle, to go beyond the constant field approximation.

For example, in the $SU(2)$ $\mathcal{N} = 4$ theory with the classical scalar field value producing the mass parameter $X^2 = |\Phi|^2$, the action in the background $F_{mn} = F_{mn} \sigma^2$, with $F_{mn}$ having eigen-values $f_1$ and $f_2$, is given by [8, 18]\(^6\)

$$\Gamma = \frac{4V_4}{(4\pi)^2} \int_0^\infty \frac{dt}{t^3} e^{-tX^2} \frac{f_1 t}{\sinh f_1 t} \frac{f_2 t}{\sinh f_2 t} \left( \cosh f_1 t - \cosh f_2 t \right)^2.$$  
(3.1)

\(^5\)Our $\mathcal{N} = 1$ conventions correspond to [13].

\(^6\)Here we consider the action in Minkowski space and hence the sign of $\Gamma$ is opposite to that in [8, 18].
Expanding in powers of \( f_n \sim F \) one finds that there is no \( F^6/X^8 \) term, while the \( F^8/X^{12} \) term has the structure different from the one that appears in the expansion of the abelian BI action (with the scale set up by \( X \)):

\[
L_{\text{BI}} = X^4 \sqrt{(1 + f_1^2/X^4)(1 + f_1^2/X^4)} - 1.
\]

The \( F^8 \) terms in the BI and SYM actions are thus different combinations of the \( F^8 \)-type superinvariants.

Below we shall find how to “supersymmetrize” the bosonic expression (3.1). Using the background field formulation [19] for general \( \mathcal{N} = 2 \) super Yang-Mills theories in \( \mathcal{N} = 2 \) harmonic superspace [20], it was shown [22] that under some restrictions on the background \( \mathcal{N} = 2 \) vector multiplet \( W = \{ W_\alpha, \Phi \} \), the one-loop effective action of \( \mathcal{N} = 4 \) SYM admits a simple functional representation in terms of \( \mathcal{N} = 1 \) superfields

\[
\exp(i \Gamma) = \int D\bar{V} DV \exp \left\{ i \int d^8z \bar{V} \Delta V \right\},
\]

where the operator \( \Delta \) is defined by

\[
\Delta = D^\alpha D_\alpha + W^\alpha D_\alpha - \bar{W}_\dot{\alpha} \bar{D}^{\dot{\alpha}} - |\Phi|^2.
\]

The integration in (3.2) is carried out over complex unconstrained \( \mathcal{N} = 1 \) superfields \( V, \bar{V} \).

The algebra of \( \mathcal{N} = 1 \) gauge-covariant derivatives is

\[
[D_\alpha, \bar{D}_{\dot{\alpha}}] = -2i D_{\alpha \dot{\alpha}} , \quad [D_\alpha, D_\beta] = i F_{ab}
\]

\[
[D_{\alpha \dot{\alpha}}, D_\beta] = -2i \varepsilon_{\alpha \beta \dot{\alpha} \dot{\beta}} \dot{W}_\dot{\alpha} , \quad [D_{\alpha \dot{\alpha}}, \bar{D}_{\dot{\beta}}] = -2i \varepsilon_{\dot{\alpha} \dot{\beta}} W_\alpha ,
\]

where

\[
F_{\alpha \dot{\alpha}, \beta \dot{\beta}} = (\sigma^a)_{\alpha \dot{\alpha}} (\sigma^b)_{\beta \dot{\beta}} F_{ab} = -i \varepsilon_{\alpha \beta \dot{\alpha} \dot{\beta}} \dot{D}_{(\dot{\alpha} \dot{\beta})} W_{\beta} - i \varepsilon_{\dot{\alpha} \dot{\beta}} D_{(\dot{\alpha} \dot{\beta})} W_{\alpha}.
\]

For a simple superfield background

\[
D_\alpha W_\beta = D_{(\alpha W_\beta)} = \text{const} , \quad \Phi = \text{const}
\]

the effective action can be exactly computed using the superfield proper time technique (see [13] for a review), and the result is [23]

\[
\Gamma = \frac{1}{64\pi^2} \int d^8z \int_0^\infty \frac{dt}{t^3} W^2 W^2 \exp(-t|\Phi|^2)
\]

\[
\times \text{tr} \left[ \left( \frac{e^{t M} - 1}{M} \right) \left( \frac{e^{-t M} - 1}{M} \right) \right] \text{tr} \left[ \left( \frac{e^{\dot{t} M} - 1}{M} \right) \left( \frac{e^{-\dot{t} M} - 1}{M} \right) \right] \det \left( \frac{t F}{\sin(t F)} \right)^{\frac{1}{2}}
\]

\[
= \frac{1}{16\pi^2} \int d^8z \int_0^\infty \frac{dt}{t^3} \bar{W}^2 \bar{W}^2 \exp(-t|\Phi|^2)
\]

\[
\times \det \left( \frac{e^{t M} - 1}{M} \right) \det \left( \frac{e^{\dot{t} M} - 1}{M} \right) \det \left( \frac{t F}{\sin(t F)} \right)^{\frac{1}{2}},
\]

(3.7)
where
\[ M^{\alpha \beta} = D_\alpha W^\beta = 2i F^{\alpha \beta}, \quad \bar{M}^{\dot{\alpha} \dot{\beta}} = -\bar{D}_\dot{\alpha} \bar{W}^{\dot{\beta}} = -2i \bar{F}^{\dot{\alpha} \dot{\beta}}. \] (3.8)

The effective action is ultraviolet and infrared finite.

To bring eq. (3.7) to a more useful form, we first note
\[ \text{tr} \left[ \left( \frac{e^{tM} - 1}{M} \right) \left( \frac{e^{-tM} - 1}{M} \right) \right] = \frac{4}{B^2} \left( 1 - \cosh(tB) \right), \] (3.9)

where
\[ B^2 \equiv \frac{1}{2} \text{tr}(M^2) = \frac{1}{4} D^2 W^2. \] (3.10)

In terms of the two invariants of the electromagnetic field
\[ \mathcal{F} = \frac{1}{4} F^{ab} F_{ab}, \quad \mathcal{G} = \frac{1}{4} \ast F^{ab} F_{ab}, \] (3.11)

we find that for the background under consideration one has
\[ B^2 = 2(\mathcal{F} + i \mathcal{G}), \] (3.12)

and
\[ \frac{1}{16} D^2 \bar{D}^2 (W^2 \bar{W}^2) = \frac{1}{16} D^2 W^2 \bar{D}^2 \bar{W}^2 = B^2 \bar{B}^2 = 4(\mathcal{F}^2 + \mathcal{G}^2). \] (3.13)

Then [24]
\[ \det \left( \frac{tF}{\sin(tF)} \right)^{1/2} = \frac{2i t^2 \mathcal{G}}{\cosh t \sqrt{2(\mathcal{F} + i \mathcal{G}) - \cosh t \sqrt{2(\mathcal{F} - i \mathcal{G})}}} \]
\[ = \frac{1}{2} \frac{t^2 (B^2 - \bar{B}^2)}{\cosh(tB) - \cosh(tB)}, \] (3.14)

and therefore the component form of the effective action is (which is equivalent to the one in (3.1))
\[ \Gamma = \frac{1}{4 \pi^2} \int d^4 x \int_0^\infty \frac{dt}{t^3} \exp(-t|\Phi|^2) \times \left( \cosh t \sqrt{2(\mathcal{F} + i \mathcal{G})} - 1 \right) \left( \cosh t \sqrt{2(\mathcal{F} - i \mathcal{G})} - 1 \right) \]
\[ \times \frac{2i t^2 \mathcal{G}}{\cosh t \sqrt{2(\mathcal{F} + i \mathcal{G})} - \cosh t \sqrt{2(\mathcal{F} - i \mathcal{G})}}. \] (3.15)

The superfield effective action is
\[ \Gamma = \frac{1}{8 \pi^2} \int d^8 z \int_0^\infty dt \ t \ W^2 \bar{W}^2 \ \exp(-t|\Phi|^2) \times \left[ \frac{\cosh(tB) - 1}{t^2 B^2} \right] \left[ \frac{\cosh(tB) - 1}{t^2 \bar{B}^2} \right] \frac{t^2 (B^2 - \bar{B}^2)}{\cosh(tB) - \cosh(tB)}, \] (3.16)
After a simple rescaling of the proper-time integral, we can rewrite the action as follows
\[
\Gamma = \frac{1}{8\pi^2} \int d^8z \int_0^{\infty} dt \, e^{-t} \frac{W^2 W^2}{\Phi^2 \Phi^2} \\
\times \frac{\cosh(t\Psi) - 1}{t^2\Psi^2} \frac{\cosh(t\bar{\Psi}) - 1}{t^2\bar{\Psi}^2} \frac{t^2(\Psi^2 - \bar{\Psi}^2)}{\cosh(t\Psi) - \cosh(t\bar{\Psi})},
\]
(3.17)
with $\Psi$ and $\bar{\Psi}$ defined in eq. (2.19).

Let us introduce the following function
\[
\omega(x, y) = \omega(y, x) = \frac{\cosh x - 1}{x^2} \frac{\cosh y - 1}{y^2} \frac{x^2 - y^2}{\cosh x - \cosh y} - \frac{1}{2}
\]
(3.18)
\[
\omega(0, y) = \omega(x, 0) = 0.
\]

Then the effective action can be rewritten in the form
\[
\Gamma = \frac{1}{16\pi^2} \int d^8z \frac{W^2 W^2}{\Phi^2 \Phi^2} \\\n+ \frac{1}{8\pi^2} \int d^8z \int_0^{\infty} dt \, e^{-t} \frac{W^2 W^2}{\Phi^2 \Phi^2} \omega(t\Psi, t\bar{\Psi}).
\]
(3.19)

Now we come to the key point. Until now we have used the constant field approximation (3.6). However, in eq. (3.19) we may no longer assume such an approximation. The effective action of $\mathcal{N} = 4$ SYM should be superconformal invariant, but $\Psi$ and $\bar{\Psi}$ are basically the only superconformal scalars constructed from both $W_\alpha$ and $\Phi$ (modulo contributions involving the free equations of motion terms $D^a W_\alpha$ and $D^2 \Phi$ and higher derivative invariants, see sec. 2). Thus the effective action (3.19) is manifestly invariant under $\mathcal{N} = 1$ superconformal transformations!

Of course, the effective action should not only be manifestly $\mathcal{N} = 1$ superconformal, but $\mathcal{N} = 2$ superconformal as well. One can restore a $\mathcal{N} = 2$ superconformal form of $\Gamma$ simply by noting that $\Psi$ is a part (2.17) of the leading $\mathcal{N} = 1$ component of $\Psi$.

As follows from (3.18) and (3.19), $\Gamma$ contains contributions of the two types
\[
S_1 = \int d^8z \frac{W^2 W^2}{\Phi^2 \Phi^2},
\]
(3.20)
\[
S_3^{(m,n)} = \int d^8z \frac{W^2 W^2}{\Phi^2 \Phi^2} \Psi^{2m} \bar{\Psi}^{2n}, \quad m, n \neq 0.
\]
(3.21)

Using the identities
\[
\frac{1}{16} D^4 \ln W = \frac{1}{4} D^2 \left( \frac{W^2 W^2}{\Phi^2} \right) + \ldots,
\]
\[
\frac{1}{4} (D^2)^2 \frac{1}{W^{2m}} = - \frac{2m(2m + 1)}{\Phi^{2m}} \frac{W^2 W^2}{\Phi^2} + \ldots,
\]
(3.22)
where dots denote terms involving derivatives of $\Phi$, we observe that the $\mathcal{N} = 2$ extensions of $S_1$ and $S_3$ are

$$ S_1 = \int d^{12}z \ln \frac{\mathcal{W}_\mu}{\mu} \ln \frac{\bar{\mathcal{W}}}{\mu}, \quad (3.23) $$

$$ S_3^{(m,n)} = \frac{1}{2m(2m+1)2n(2n+1)} \int d^{12}z \Psi^{2m} \bar{\Psi}^{2n}. \quad (3.24) $$

Let $\Omega(x, y) = \Omega(y, x)$ be the analytic function related to $\omega(x, y)$ as follows: if

$$ \omega(x, y) = \sum_{m,n=1}^{\infty} c_{m,n} x^{2m} y^{2n}, \quad (3.25) $$

then

$$ \Omega(x, y) = \frac{1}{4} \sum_{m,n=1}^{\infty} c_{m,n} m(2m+1)n(2n+1) x^{2m} y^{2n}. \quad (3.26) $$

Then the manifestly $\mathcal{N} = 2$ superconformal form of $\Gamma$ is

$$ \Gamma = \frac{1}{16\pi^2} \int d^{12}z \ln \frac{\mathcal{W}_\mu}{\mu} \ln \frac{\bar{\mathcal{W}}}{\mu}, $$

$$ + \frac{1}{8\pi^2} \int d^{12}z \int_0^\infty dt \ e^{-t} \Omega(t\Psi, t\bar{\Psi}). \quad (3.27) $$

Here the first term was computed in [22, 25] (see also [15, 16, 17]).

As is seen from (3.27), the one-loop effective action of $\mathcal{N} = 4$ SYM does not contain terms described by the “second” superconformal invariant (2.8). In particular, there are no $F^6$-type corrections generated by

$$ \int d^{12}z \frac{1}{\mathcal{W}^2} \ln \frac{\mathcal{W}_\mu}{\mu} D^4 \ln \frac{\mathcal{W}}{\mu}. \quad (3.28) $$

Such terms are expected to appear at the 2-loop order.

The absence of this “$F^6$” correction at the 1-loop order is a unique feature of the maximally supersymmetric $\mathcal{N} = 4$ super Yang-Mills theory (which, as discussed in the Introduction, is crucial for supergravity–SYM correspondence at the subleading order). As we are going to demonstrate in the next section, this property is no longer true in generic $\mathcal{N} = 2$ superconformal models.

It may be instructive to compare the low-energy action (3.19) with the $\mathcal{N} = 1$ supersymmetric Born-Infeld action [26]

$$ S_{BI} = \frac{1}{4} \int d^6z \mathcal{W}^2 + \frac{1}{4} \int d^6\bar{z} \bar{\mathcal{W}}^2 + \frac{1}{X^4} \int \frac{W^2 \bar{W}^2}{1 + \frac{1}{2} a + \sqrt{1 + a + \frac{1}{4} b^2}}, \quad (3.29) $$

$$ a = \frac{1}{2X^4} \left(D^2 \mathcal{W}^2 + \bar{D}^2 \bar{\mathcal{W}}^2\right), \quad b = \frac{1}{2X^4} \left(D^2 \mathcal{W}^2 - \bar{D}^2 \bar{\mathcal{W}}^2\right), \quad (3.29) $$
where we used $1/X$ as a scale parameter. The non-trivial last term here has the structure similar to that of $\Gamma$ in (3.19), with $X^2$ playing the role of $|\Phi|^2$. While the two actions coincide at the leading $W^2\bar{W}^2$ order, they contain different combinations of invariants at higher orders (see also the discussion in Introduction). In particular, the subleading $^*F^{6\alpha}$ term which was absent in the 1-loop $\mathcal{N} = 4$ SYM effective action is present in the BI action (3.29) and has the form

$$\frac{-1}{8X^8} \int d^8z \, W^2 \bar{W}^2 \left( D^2 W^2 + \bar{D}^2 \bar{W}^2 \right). \quad (3.30)$$

\section{$\mathcal{N} = 2$ superconformal models}

In this section we shall consider a special $\mathcal{N} = 2$ superconformal theory – the $\mathcal{N} = 2$ $SU(N)$ super Yang-Mills model with $2N$ hypermultiplets in the fundamental representation; the effective action of generic $\mathcal{N} = 2$ superconformal models [27] can be analyzed in a similar fashion. For simplicity, only the case of $N = 2$ will be discussed, with the gauge group $SU(2)$ spontaneously broken to its $U(1)$ subgroup.

Both $\mathcal{N} = 2$ SYM and hypermultiplet models are superconformal invariant at the classical level. Their quantum effective actions include the scale independent non-holomorphic terms besides standard divergent and holomorphic scale dependent contributions. For special combinations of these models divergent and holomorphic contributions cancel out and the full quantum effective action is superconformal invariant.

For computing the one-loop low-energy effective action of a hypermultiplet coupled to a background abelian $\mathcal{N} = 2$ vector multiplet it is sufficient to make use of the simplest realization of the hypermultiplet in terms of two $\mathcal{N} = 1$ covariantly chiral superfields $\phi_1$ and $\phi_1$ with opposite $U(1)$ charges $e = \pm 1$, with the action

$$S = \int d^8z \left( \bar{\phi}_1 \phi_1 + \bar{\phi}_2 \phi_2 \right) + \left\{ i \int d^6z \, \Phi \phi_1 \phi_2 + \text{c.c.} \right\}, \quad \bar{\mathcal{D}}_a \phi_{1,2} = 0. \quad (4.1)$$

In the constant field approximation (3.6), the effective action is given by a functional determinant of the D’Alambertian

$$\Delta_c = \mathcal{D}^a \mathcal{D}_a + W^a \mathcal{D}_a - |\Phi|^2, \quad (4.2)$$

which acts on the space of covariantly chiral superfields. The effective action is [28, 29, 23]

$$\Gamma_{hm} = \frac{1}{16\pi^2} \int_{t_2}^{\infty} \frac{dt}{t} \exp(-t|\Phi|^2) \int d^6z \, W^2 \times \frac{\cosh(tB) - 1}{t^2 B^2} \frac{(B^2 - \bar{B}^2)t^2}{\cosh(tB) - \cosh(t\bar{B})}, \quad (4.3)$$
where $\epsilon \to 0$ is a UV cutoff.

The form of $\Gamma_{hm}$ is determined by the function

$$
\lambda(x, y) = \frac{\cosh x - 1}{x^2} \frac{x^2 - y^2}{\cosh x - \cosh y}, \quad \lambda(x, 0) = 1 .
$$

(4.4)

It is useful to introduce a new function $\zeta(x, y)$ related to $\lambda$ by

$$
\lambda(x, y) - 1 = -y^2 \zeta(x, y),
\zeta(x, y) = \zeta(y, x) = \frac{y^2(\cosh x - 1) - x^2(\cosh y - 1)}{x^2 y^2 (\cosh x - \cosh y)} .
$$

(4.5)

Recalling the definition $\bar{B}^2 = \frac{1}{4} \bar{D}^2 \bar{W}^2$, we can rewrite the effective action as follows

$$
\Gamma_{hm} = \frac{1}{16 \pi^2} \int_{\epsilon}^{\infty} \frac{dt}{t} \exp(-t|\Phi|^2) \int d^6 z W^2
- \frac{1}{16 \pi^2} \int_{0}^{\infty} \frac{dt}{t} \exp(-t|\Phi|^2) \int d^6 W^2 t^2 \bar{B}^2 \zeta(tB, t\bar{B}) ,
$$

(4.6)

i.e.

$$
\Gamma_{hm} = -\frac{1}{16 \pi^2} \int d^6 W^2 \ln \frac{\Phi}{\mu} + \text{c.c.}
+ \frac{1}{16 \pi^2} \int d^8 z \int_{0}^{\infty} dt \, t e^{-t} \frac{W^2 \bar{W}^2}{\Phi^2 \bar{\Phi}^2} \zeta(t\bar{\Psi}, t\Psi) ,
$$

(4.7)

where we have absorbed the UV cutoff into the renormalization scale $\mu$. Here the first term (holomorphic contribution) may be derived also by other well known methods\(^7\) (see, e.g. [31]).

In the $\mathcal{N} = 2$ superconformal theories holomorphic contributions cancel out. Let us recall how this happens for the present model with 4 fundamental hypermultiplets. Each hypermultiplet has two $SU(2)$ components, so that altogether we have 8 abelian hypermultiplets with charges $e = \pm \frac{1}{2}$ with respect to the unbroken $U(1)$ generated by $\frac{1}{2} \sigma_3$. In addition, we have the adjoint ghost superfields or two hypermultiplets with $U(1)$ charges $e = \pm 1$. The charges may be accounted for by replacing $W_\alpha$ and $\Phi$ in the effective action by

$$
W_\alpha \to eW_\alpha , \quad \Phi \to e\Phi .
$$

(4.8)

\(^7\)In obtaining eq. (4.7), we concentrated on the quantum corrections involving the vector multiplet strength and did not take into account the effective Kähler potential $K(\Phi, \bar{\Phi}) = -\frac{1}{16 \pi^2} \Phi \bar{\Phi} \ln(\Phi \bar{\Phi}/\mu^2) = \bar{\Phi} \mathcal{F}(\Phi) + \Phi \bar{\mathcal{F}}(\Phi)$ generated by the holomorphic Seiberg potential $\mathcal{F}(\Phi) = -\frac{1}{12 \pi^2} \Phi^2 \ln(\Phi/\mu)$. A derivation of $K(\Phi, \bar{\Phi})$ in the framework of the superfield proper time technique, which we used in this paper, can be found in [30, 13].
Then the complete effective action is
\[
\Gamma = 8 \times \frac{1}{16\pi^2} \int d^8z \int_0^\infty dt \, e^{-t} \frac{W^2\bar{W}^2}{\Phi^2\bar{\Phi}^2} \zeta(2t\Psi, 2t\bar{\Psi}) \\
- 2 \times \frac{1}{16\pi^2} \int d^8z \int_0^\infty dt \, e^{-t} \frac{W^2\bar{W}^2}{\Phi^2\bar{\Phi}^2} \zeta(t\Psi, t\bar{\Psi}) \\
+ \frac{1}{8\pi^2} \int d^8z \int_0^\infty dt \, e^{-t} \frac{W^2\bar{W}^2}{\Phi^2\bar{\Phi}^2} \left\{\omega(t\Psi, t\bar{\Psi}) + \frac{1}{2}\right\},
\]
with the function \(\omega(x, y)\) defined in (3.18). Here the last term coincides with the effective action (3.19) of \(\mathcal{N} = 4\) SYM\(^8\).

Note that since
\[
\zeta(x, 0) = \frac{\cosh x - 1 - \frac{1}{2}x^2}{x^2(\cosh x - 1)},
\]
the effective action now contains the \(\mathcal{N} = 2\) superconformal invariants of the type (2.8) (and, in particular, the “\(F^6\)” contributions (3.28)) which were absent in the \(\mathcal{N} = 4\) case.

5 Conclusions

Let us summarize the results obtained.

We described the superconformal invariants which are constructed in terms of the \(\mathcal{N} = 2\) abelian vector multiplet and play the role of building blocks for the low-energy effective actions of \(\mathcal{N} = 2\) or \(\mathcal{N} = 4\) superconformal theories on the Coulomb branch. We then computed the one-loop effective actions in constant \(\mathcal{N} = 2\) field strength background in \(\mathcal{N} = 4\) SYM theory and in a particular \(\mathcal{N} = 2\) SU(2) gauge theory.

The fact that the theories under consideration are superconformal, allowed us to go beyond the constant field approximation and to restore, with the aid of the classification of superconformal invariants, the one-loop effective actions (1.4) (with \(\Lambda\) and \(\Upsilon\) being special model-dependent functions). These actions generate contributions which in components have the form (1.1) (with no coupling constant prefactors since we consider the 1-loop approximation).

The crucial difference between the \(\mathcal{N} = 4\) SYM theory and generic \(\mathcal{N} = 2\) superconformal models is that the second term in (1.4) is absent at the one-loop level in \(\mathcal{N} = 4\) SYM.

\(^8\)The \(\mathcal{N} = 4\) SYM theory is equivalent to the \(\mathcal{N} = 2\) SYM coupled to a single hypermultiplet in the adjoint representation; in this case, the hypermultiplet and the ghost contributions cancel each other, and the effective action is given by the last term in (4.9).
The first term in (1.4), which generates $F^4$-corrections, is known to be one-loop exact [1]. It would be of interest to study if there are possible non-renormalization theorems for the quantum corrections which are given by the second and the third terms in (1.4) for particular choices of the function $\Lambda$ and $\Upsilon$.

Acknowledgements

I.B. and S.K. are glad to acknowledge the participation of A. Petrov at early stage of this work. S.K. benefited from discussions with E. Ivanov and S. Theisen. We would like to acknowledge the support of the NATO collaborative research grant PST.CLG 974965. The work of I.B. and S.K. was partially supported by the RFBR grant No.99-02-16617, by the INTAS grant No.96-0308 and by the DFG-RFBR grant No.99-02-04022. I.B. was also supported by the GRACENAS grant No.97-6-2-34, FAPESP and thanks the Institute of Physics at the University of Sao Paulo for hospitality. The work of A.T. was supported in part by the DOE grant DOE/ER/01545-779, by the EC TMR grant ERBFMRX-CT96-0045 and by the INTAS grant No.96-538.

Appendix A  Superconformal transformations

In this appendix we collect basic properties of $\mathcal{N} = 1, 2$ superconformal transformations (see, for instance, refs. [13, 14] for more details). In $\mathcal{N} = 1, 2$ global superspace $\mathbb{R}^{4|4\mathcal{N}}$ parametrised by $z^A = (x^a, \theta^i, \bar{\theta}^\dot{i})$, infinitesimal superconformal transformations

$$ z^A \to z^A + \xi^A $$

(A.1)

are generated by superconformal Killing vectors

$$ \xi = \bar{\xi} = \xi^A D_A = \xi^a(z) \partial_a + \xi^i(z) D^i + \bar{\xi}^\dot{i}(z) \bar{D}^\dot{i} \quad \text{(A.2)} $$

defined to satisfy

$$ [\xi, D^j_{\alpha}] \propto D^j_{\beta} \quad \text{(A.3)} $$

From here one gets

$$ \xi^a_i = -\frac{i}{8} \bar{D}_{\dot{\beta}} \xi^{\dot{\beta} a}, \quad \bar{D}_{\dot{\beta}} \xi^a_i = 0 \quad \text{(A.4)} $$

while the vector parameters satisfy the equation

$$ D^i_{(\alpha \dot{\beta}) \dot{\beta}} = D_i (\alpha \dot{\beta}) = 0 \quad \text{(A.5)} $$
implying, in turn, the conformal Killing equation
\[ \partial_a \xi_b + \partial_b \xi_a = \frac{1}{2} \eta_{ab} \partial_c \xi^c . \] (A.6)

From eqs. (A.4) and (A.5) one gets
\[ [\xi , D^i] = - (D^i_{\alpha \beta} \xi^\beta )_i = \hat{\omega}^{\alpha \beta} D^i_{\alpha \beta} - \frac{1}{N} ( (N - 2) \sigma + 2 \bar{\sigma} ) D^i_{\alpha} - i \hat{\Lambda}^i_j D^j_{\alpha} . \] (A.7)

Here the parameters of ‘local’ Lorentz \( \hat{\omega} \) and scale–chiral \( \sigma \) transformations are
\[ \hat{\omega}_{\alpha \beta} (z) = - \frac{1}{N} D^i_{(\alpha \xi^\beta)} , \quad \sigma (z) = \frac{1}{N(N - 4)} \left( \frac{1}{2} (N - 2) D^i_{\alpha} \xi^\alpha - D^i_{\alpha} \hat{\bar{\sigma}}^i \right) \] (A.8)

and turn out to be chiral
\[ \bar{D}^i_{\dot{\alpha}} \hat{\omega}_{\alpha \beta} = 0 , \quad \bar{D}^i_{\dot{\alpha}} \sigma = 0 . \] (A.9)

The parameters \( \hat{\Lambda}^i_j \)
\[ \hat{\Lambda}^i_j (z) = - \frac{1}{32} \left( [D^i_{\alpha} , \bar{D}^j_{\beta}] - \frac{1}{N} \delta^i_j [D^k_{\alpha} , \bar{D}^i_{\dot{\alpha} k}] \right) \xi^{\dot{\alpha} \alpha} , \quad \hat{\Lambda}^i = \hat{\Lambda} \quad \text{tr} \hat{\Lambda} = 0 \] (A.10)

appear only in the \( N = 2 \) case and correspond to ‘local’ \( SU(2) \) transformations. One can readily check the identities
\[ D^k_{\alpha} \hat{\Lambda}^i_j = 2 i \left( \delta^k_j D^i_{\alpha} - \frac{1}{N} \delta^i_j D^k_{\alpha} \right) \sigma , \]
\[ D^i_{\alpha} \hat{\omega}_{\beta \gamma} = 2 \varepsilon_{\alpha(\beta} D^i_{\gamma)} \sigma , \] (A.11)

along with
\[ D^i_{\alpha} D^j_{\beta} \sigma = 0 . \] (A.12)
