**Synthetic Methods**

**Pd-Catalyzed Directed Thiocyanation Reaction by C–H Bond Activation**

Mélissa Gao†, Mu-Yi Chen†, Xavier Pannecoucke, Philippe Jubault, and Tatiana Besset‡(†)

Abstract: The Pd-catalyzed directed thiocyanation reaction of arenes and heteroarenes by C–H bond activation was achieved. In the presence of an electrophilic SCN source, this original methodology offered an efficient tool to access a panel of functionalized thiocyanated compounds (21 examples, up to 78% yield). Post-functionalization reactions further demonstrated the synthetic utility of the approach by converting the SCN-containing molecules into value-added scaffolds.

Over the years, the direct functionalization of a simple C–H bond by transition metal catalysis became an efficient and pivotal tool in organic chemistry, answering to the increasing demand for more sustainable chemical transformations.[1],[2] Indeed, an array of methodologies was developed to build up a C–N, C–O, C–X or C–C bond. However, less attention was paid to the formation of the C–S bond by transition metal catalyzed C–H bond activation[2] as sulfur poisoning of the transition metal might be a problem to circumvent.[3] Nevertheless, key advances were made by several research groups using Pd[2],[4], Rh,[5] Ru,[5] Cu,[5] Co,[5] and Ni-catalysts, among others (Scheme 1).[5a,b] These major contributions brought synthetic solutions for making C–S bonds generally using di(hetero)aryl disulfides as coupling partners. In sharp contrast, the directed thiocyanation reaction by transition metal catalysis is still elusive, and the existing methods are based on the functionalization of innate positions. Convinced about the key role of organothiocyanate compounds,[5a,b] for agrochemicals and medicinal chemistry along with the synthetic utility of the SCN residue as a linchpin[6] to access a large variety of sulfur-containing molecules,[5] we thought that the development of a new tool for the direct introduction of a SCN moiety by transition metal catalyzed C–H bond activation is of prime importance and constitutes today a challenge.

To this end, in course of our research program dedicated to the development of new methodologies to build up C–S bonds by transition metal catalyzed C–H bond activation,[7] we report herein an unprecedented directed Pd-catalyzed thiocyanation reaction by C–H bond activation.

At the outset of this study, the 2-phenylpyridine was selected as the model substrate (Table 1). Pleasingly, in the presence of N-(thiocyanato)phthalimide as the electrophilic SCN source and using a catalytic amount of PdCl₂, the mono-thiocyanation of 1a occurred, affording the product 2a in 67% yield (Table 1, entry 1). Then, several parameters were investigated to further improve the efficiency of the transformation. First, different catalysts were tested (Table 1, entries 2–5) and PdCl₂ turned out to be the best one. It must be noted that when the catalyst loading was decreased (Table 1, entry 6), a significant drop of the yield was observed (37% vs. 67%). The replacement of DMF by other solvents did not improve the reactivity (Table 1, entries 7–10) and the temperature as well as the time turned out to be key parameters in this transformation (Table 1, entries 11–14). When other electrophilic SCN sources (II–IV) were provided the original work is properly cited, the use is non-commercial and no modifications or adaptations are made.

Scheme 1. State of the art on transition metal catalyzed directed C–S bond formation by Cl(sp²)–H bond activation and the present work.

formed without catalyst (Table 1, entry 20) and no product was observed, which confirmed the importance of the Pd$^{II}$ catalyst in that transformation.

With the optimized reaction conditions in hand, a series of 2-phenylpyridine derivatives was evaluated (Scheme 2). The thiocyanation of the 2-phenylpyridine 1a provided selectively an access to the mono-functionalized product 2a in 63% yield and the reaction was easily scaled up on a gram scale, affording 2a in 40% yield. When the naphthalene derivative 1b was used, the expected product 2b was obtained in 53% yield and its structure was further confirmed by X-ray analysis (CCDC 1993683).

Even ortho- (1o) and ortho, meta-disubstituted (1p) derivatives were suitable substrates. It must be noted that the transformation was tolerant to halogens (2f–2h, 2p) and fluorinated groups (2h–2j), although no reaction was observed with compounds bearing more sensitive functional groups such as alcohol, amine, nitrile.

Pleasingly, when an heteroaromatic substrate namely the 2-(2-thienyl)pyridine was reacted, the methodology furnished the corresponding product 2q in 41% yield.

A control experiment was conducted in the absence of Pd-catalyst using 1p and 1q as starting materials and no product was observed, which allowed us to rule out a Friedel–Crafts type reaction. Finally, when substrates bearing a pyrimidine or a pyrazole as directing groups were used, the expected products 2r and 2s were obtained in lower yields (44% and 28% yields, respectively).

We were pleased to see that our methodology was also applied to the thiocyanation of the N-pyrimidine carbazole 3 and the benzo[h]quinoline 5, offering an access to the corresponding products 4 and 6 in 33% and 78% yields, respectively.

Table 1. Optimization studies for the thiocyanation of the 2-phenylpyridine 1a.$^{[a]}$

| Entry | Catalyst | Solvent | SCN source | Yield [%] |
|-------|----------|---------|------------|-----------|
| 1     | PdCl$_2$ | DMF     | I          | 67        |
| 2     | PdBr$_2$ | DMF     | I          | 18        |

(Scheme 3). To further demonstrate the synthetic utility of the organothiocyanate compounds, the SCN residue was easily converted into high value-added groups (Scheme 4). The tetrazole 7 was synthesized by reacting 2a with NaN₃ via a [3+2]-cycloaddition reaction. Then, the trifluoromethylthiolation of the derivative 2c was carried out using the conditions described by Gooßen, leading to the corresponding product 8 in 43% yield.

Based on the literature, the following mechanism was suggested (Scheme 5). The metallacycle formation (intermediate A) followed by an oxidative addition with the reagent I, would provide the Pd⁹ intermediate B. Finally, a final reductive elimination would afford the expected product 2a and regenerate the catalyst.

In summary, the regioselective Pd-catalyzed directed monothiocyanation of 2-phenylpyridine and heteroarene derivatives by C–H bond activation was developed. With this innovative methodology, a panel of aromatic derivatives was functionalized in moderate to good yields (21 examples, up to 78% yield). Finally, the introduction of the thiocyanate group as a “synthetic transformable handle” reinforced the synthetic utility of the depicted method as it opened several possibilities towards a large variety of high value-added compounds. To this end, post-functionalization reactions were smoothly achieved. We believe that this original approach to build up C–SCN bond by C–H bond activation will be useful for the organic chemistry community and will open new avenues towards further investigations regarding the potential of the SCN group.
